THE
GARDEN

The title 'THE GARDEN' is rendered in a highly decorative, gold-tooled serif font. The letters are thick and feature intricate internal patterns, including floral and vine motifs. The word 'THE' is positioned above 'GARDEN'. The entire title is surrounded by elaborate, raised gold designs of leaves, stems, and small flowers, creating a lush, garden-like appearance. The background is a dark green, textured material, possibly leather or cloth.

Anthurium at Kew, 520
Antirrhinum siculum, 136
 Ants, modes of destroying, 165, 314; *versus* caterpillars, 74
Aphelandra aurantiaca Roezlii, 398
Aponogeton distachyon, 310, 523
 Apple grub, remedy for, 359
 Apple trees, cordon, 330; for ornament, 339, 371, 382; old espalier, 507; bloom and fruit on the same tree at the same time, 300; on the French Paradise, 451
 Apples, 187; American, 500; Newtown Pippin, 473; and Holly berries, scarcity of, 486; as food, 254; from Brit-

tany, 310; from France, 353; in Australia, 473; keeping, 187; ditto in gypsum, 524; ditto in plaster of Paris, 373; Michigan, 310; Siberian crab, 310
 Aquarium at Brighton, 245; at Yarmouth, 335
Aquilegia californica, 20
Arabia japonica, 8, 438, 478; hardiness of, 410
Araucarias, variegated, 465; at Pitt-down, 311
 Arboretum for Walsall, 498; the Arnold, 335; the Derby, 446
 Architecture, rustic, 555
Aristolochia Duchartrei, 438
 Ar-nut, 100
Artemisia anethifolia, 115
Arthropodium paniculatum, 462
Artichauts farcis a l'Italienne, 215
 Artichokes, exterminating Jerusalem, 434
 Art o. Nature, 148
Arum corsicum, 250
Arundo conspicua, 136; *versicolor*, 295
 Asa Gray on geographical distribution of plants, 337, 530
Asclepias princeps, 98; *tuberosa*, 115, 250
 Asparagus-growing company, an, 210
Asparagus, salting, 241; strong-growing, 512
Asplenium flagelliforme, 203
Asier turbinellus, 318
 Asters, culture of, 205
Aubrietia as a wall plant, 195
 Australian products, 543
 Autumn sowing, Stocks for, 72
 Autumn sown Sweet Peas, 73
 Avocado Pear, 55
 Ayrton, Mr., and Dr. Hooker, 42, 48, 62, 91, 113, 137, 168, 176, 188, 218, 246, 307, 355

B.

Bamboos, 464; hardy, 316, 428; rapid growth of, 238; rates of growth of, 335
 Banana, culture of, 136; eating, 306
 Banyan tree, 380
Barbarea vulgaris variegata, 452
 Baskets, Strawberries for hanging, 34
 Baths, park, 128
 Battersea Park in 1872, 179; carpet bedding at, 273
 Beach Plum, 450, 500
Beaucarnea, the genus, 480
 Bedding out, 394, 503; a defence and a reply, 265, 287, 333, 406; ugly examples of, 163
 Bedding plants, annual distribution of, 335; hardy *Heatus* as, 527
 Bee, death from sting of a, 88, 314
 Beech trees and lightning, 322, 339
 Bees and *Salyias*, 369
Begonia, 409; for winter flowering, 441; *Weltoniensis*, 92
 Belfast Botanic Garden, 413
 Belgium, gardening in, 99
 Belladonna Lily, the, 506
 Bellows sprinkler, the, 232
Berberis fascicularis, 172
 Bindweed, the great, 241
 Birch, a purple-leaved, 238; weeping, 197; Young's ditto, 465
 Bird, The, rev., 139
 Birds, a plea for the, 199; friends of the gardener and farmer, 432; to protect buds and seeds from, 543
 Birmingham, exhibition grounds, 309
 Birmingham Horticultural Congress, Professor Dyer's address at, 86

THE
REV. SAMUEL REYNOLDS HOLE, M.A.

THE First Volume of THE GARDEN was dedicated to the memory of one long passed away, but to whom gardening will be for ever indebted—J. C. LOUDON. The subject of our present notice is among us, in the prime of life; cheers with his presence most of our important horticultural meetings, and charms with his pen all interested in horticultural literature. Mr. HOLE is, it need not be said, well known as a florist, but he is a thousand times more endeared to the horticultural community by his genial character than ever he can be through any florist's triumphs. He is the high priest of good fellowship among gardeners of every degree. Those who have not had the pleasure of hearing any of his capital speeches, always sparkling with wit, such, for example, as those delivered at the Gardeners' Benevolent Institution, last year, may see evidence of this in many passages in the "Six of Spades," as well as in the "Book about Roses," and the "Little Tour in Ireland."

But Mr. HOLE is more especially distinguished as a florist, and it is chiefly as a florist we must speak of him in THE GARDEN, and his devotion to Rose culture has been most unremittingly followed up with an amount of success which has resulted in ample enjoyment and reward; for among Rosarians he is ungrudgingly acknowledged a head and chief. He is the founder of Rose Shows, and on such occasions is well known as a distinguished and unerring judge of that exquisite flower. Each year, as fresh varieties are brought forward by various cultivators, the never failing sagacity of his practised eye, and accomplished taste, pronounces the fiats of the "Rose King," which go forth undisputed, the condemned pretenders sinking back to the limbo of obscurity and neglect, while the favoured among the blooming throng at once take the places assigned to them in the Court of Beauty and Sweetness, without let or hindrance, and become the ruling fashion of their season, as other beauties do, attracting ever increasing crowds of willing worshippers, till new bebies, in due course, replace them in the affections of inconstant votaries. But here and there a flower of matchless beauty and perfection assumes the place of a perennial queen, to add to the permanent stock of our magnificent modern Roses, of the exquisite beauty of which the ignorant growers and admirers of the Queen of flowers in former times could have conceived no idea, even in their brightest flights of fancy, or their wildest Rosarian dreams. But these are matters too closely connected with the pride of place, and privilege, and precedency, in the Rosy Court of Sweetness and Beauty to be discussed beyond its immediate precincts; they must be left exclusively to the despotic ruling of its accomplished Lord Chamberlain, who, in his office, possesses the courtly gift of uttering even utter condemnation in such pleasant, witty words, as are more charming than another's praise; and many a fair Rose, defeated and condemned, might exclaim with *Phoebe*, in "As you like it"—

Sweet youth I pray you chide a year together;
I'd rather hear you chide, than that man woo.

But let us hear the benignant despot speak for himself; for that he has a right to do so, is sufficiently proved by what he advances in the preface to his charming "Book about Roses." "I write about Roses," he says, "because, having grown them for twenty years, having won more than thirty cups, 'open to all England,' having originated the first Rose Show, that is the first show of Roses only, and having attended most of the subsequent meetings, either as a judge or an exhibitor, I ought to have something to say worth hearing to those who love the Rose; and will try to say it, as Bassuet preached, *sans etude, familierement de l'abondance du cœur.*"

In the abundance of useful hints which he then proceeds to pour forth to us in this brilliant little volume, we are first informed how recent and how rapid have been the great advances in Rose culture; but while telling us that twenty years ago Roses were grown by the dozen, and then by the thousand, and now by the acre, he feels compelled to state, emphatically, that the number of beautiful Roses in proportion to the vast multiplication is not what it should be; he is, indeed, so fully prepared with a negative to the question, "Has beauty been produced in fair proportion to quantity?" that he facetiously calls upon his printer to furnish him with two of his biggest and blackest capitals, in order that he may sufficiently emphasize his answer, "NO." This call for the big capitals is so amusing that it fairly takes the

sting out of the condemnation, and there is consequently a hearty laugh instead of a dismal groan in the condemned cell of rejected flowers. *Phoebe* was right, one would rather be chid by a judge so witty and so genial than patted on the back by a stupid one. How pleasant he is, too, when conducted with an air of triumph by a self-satisfied amateur to one of those "dismal slaughter-houses which are called a Rosary;" our smiling judge condemns with such *bonhomme*, and illustrates his condemnation so delightfully from his inexhaustible stores of anecdote and racy narrative, that the discomfited amateur positively goes on his way rejoicing, primed with half-a-dozen capital stories which he no doubt means to retail on the very first opportunity. He has been told, *apropos* to his unsuccessful Roses, of a volume of sermons reviewed in the first volume of the *Edinburgh Review* by SIDNEY SMITH, of which sermons the witty divine remarked, as critic, that their characteristic was "decent debility"; and then, as a young Rose grower, the amateur was smilingly informed that his progress had been somewhat analogous to that of GEORGE III. when learning the fiddle, who, when he asked his master, the celebrated VIOTTI, what he thought of his pupil, received, with a profound how and courtly smile, the following reply:—"Sire, there are three classes of violinists—those who cannot play at all, those who play badly, and those who play well. Your Majesty is now *commencing to enter upon* the second of these classes." What a capital story for the defeated Rosarian to take home to dinner, and retail, over the claret, to his neighbour, who may, perhaps, fancy himself a musician. This Rosist malefactor was let lightly and pleasantly off; but there is occasionally sterner rebuke in pickle for more obstinate offenders.

With what delightful enthusiasm our great Rosarian tells of the complete devotion that is absolutely necessary to the successful culture of the Rose. Something more than the ordinary devotion of a man seems to be requisite—a degree of devotion more akin to that of the more constant sex, for, as BYRON tells us, "Man's love is of his life a thing apart, 'tis woman's whole existence," as must be that of the Rosarian to the Queen of flowers, if he wishes to be triumphantly successful; for, says Mr. HOLE, "he must have, not only the glowing admiration, the enthusiasm, and the passion, but the tenderness, the thoughtfulness, the reverence, the watchfulness of love,—with no ephemeral caprices like those of the gay 'young knight who loves and rides away'"; on the contrary, the cavalier of the Rose must have *semper fidelis* upon both crest and shield. The Rose will not submit to be treated simply as one among the many fair flowers of the garden. Her "Standard" must not be made to form the central object of a neat little circlet filled with a few "bedding plants," which, like a band of leeches, suck away the life-blood of the Rose, and though—

Around the red Rose the Convolvulus climbing,

As Mrs. HEMANS says, sounds sweetly pretty, we are told "that such would be the loveliest arrangement possible, only that unfortunately it is death to the Rose. It is in fact these pretty little floral contrivances that defeat the object of the would-be Rose grower, as our author teaches us in sober earnest, while he amuses us, and makes us laugh. "Why does Charles Lefebvre behave so disgracefully in my garden?" asked a disappointed lover of Roses of the Seer, "Because," replies the man of Rose lore, "your 'Charles Lefebvre' is placed, like Titynus, '*sub tegmine fagi*,' under the drip and shade of a noble Beech tree, whose boughs above and roots below keep all nourishment from him." The august Rose will not submit to be placed as an ornamental dummy in front of a belt of shrubbery; he must have his own special conditions ungrudgingly complied with in every iota—and then—well, one need not tell experienced Rosarians what the result will then be, in the case of Charles Lefebvre.

What charming chapters there are in this compact little volume on a variety of matters connected with Rose growing and general gardening, and how well, truthfully, and honestly they are considered and calculated, so as to bring into activity the highest and best characteristics of the true gardener. To the genuine lover of flowers not only for their beauty, but for the pure pleasures that accompany their culture, was ever such a variety of hints and counsels conveyed in pleasanter or wittier words, on such a wide range of subjects connected with horticulture, from the inculcation of a love of flowers to parish children, to pleasant vauntings over new discoveries anent the *summum bonum* of "manures," and even to the humours, how racily told, of Rose shows?

Readers of THE GARDEN are familiar with the sparkling pages of the "Six of Spades," nor need it be pointed out that every communication from Caunton Manor, of which Mr. HOLE is the happy vicar, on whatever subject, grave or gay, is sure to contain some happily-conceived phrase, some cleverly picked out word, that never fails to brighten and light up horticultural pages that might otherwise, in the hands of routine writers, become just a trifle wearying, however conscientiously done, necessary, and useful. Such a writer as Mr. HOLE is a real benefactor to horticultural literature, for he not only revels in floral beauty, with the pleasantness of a true laughing philosopher; but where so many would be dull, he cannot be so—he makes the very desert smile. Of the good effect of gardening on a rightly balanced mind, Mr. HOLE says, "I have proved from my own experience that of all outdoor exercises, horticulture is the happiest and best, and realised the truth of Lord BACON's words, 'Gardening is the purest of human plea-

tures, and the greatest refreshment to the spirit of man.'” Allowing that, as a gardener, a man may not find as much excitement as may be found in a run with the Quoru hounds, or in a day among the Heather, with plenty of grouse, he yet maintains that as a constant, life-long source of cheerful belief and innocent diversion from the work and from the inevitable sorrows of life, the recreation of horticulture surpasses all. Mr. HOLE does not affirm that gardeners are free from great failures and reverses. He is not oblivious of the mealy-bug, the red spider, the wireworm, the cockroach, the earwig, and endless tribes of beetles, caterpillars, snails, and slugs after their kinds. He admits the drawbacks of mildew, canker, and blight. He knows very well, as he pleasantly tells us, that the mellow ouzel fluting it so cheerily up in the Elm, has wet his whistle with the ripe Cherries, and proposes to wet it again. He freely admits not only being aware of, but also having experienced most of the ills that gardening is heir to, from a thunderstorm to the nibbling mouse plague; but still avers that these solitudes only enhance its joys; and that there is no month in the year, no day in the week, supposing the existence of a “bit of glass” (“who loves a garden, loves a greenhouse too,” says COWPER), when there is not something new, something beautiful to interest and please.

He tells us, with the glee of a true-hearted enthusiast, how, in the dreary month of November, he cut fine flowers of the last Roses of autumn, Gloire de Dijon, Maréchal Vaillant, and Souvenir de Malmaison; which, mixed with a few fronds of hardy Ferns and a few feathers from the plumes of the Pampas Grass, made up a by no means contemptible bouquet; and next we are told of his healthy afternoon's dig in his kitchen garden, which made him feel muscular enough to “swarm up the very greasiest pole, and eat the leg of mutton at the top of it afterwards.” He has, too, his tiny “stove” in that happy vicarage garden, from the Stephanotis on the roof of which many a fair maid of the parish and neighbourhood of Cauntou has had her bridal bouquet, and in which he is able to force a few early Strawberries—which do not merely give the grower intense pleasure by their fragrant beauty, but serve still better purposes. A doctor once sent a dozen miles for the same number of berries, and afterwards told the happy grower that they were well worth a pound apiece to his patient.

It is not only in the literature of the garden that Mr. HOLE shines so conspicuously. Everything that his pen touches is embellished by it; and, indeed, it may be fairly said, as JOHNSON inscribed upon the tomb of OLIVER GOLDSMITH, “Nullum tetigit quod non ornavit.” In evidence of this, let us refer to the charming “Little Tour in Ireland,” which is brimful of the most genial humour, and apt and characteristic description. Yet, after all, it is the literature of the garden that we wish to see most often sparkling with the ready wit and pungent pleasantries of the author of the “Six of Spades,” brightening up for us every department of horticulture, with all of which he is so pleasantly and enthusiastically conversant.

"This is an art
Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTICE.

The FIRST VOLUME of THE GARDEN will be Published early this month, and will contain an Original Portrait of the late Mr. Loudon. The Index to the Volume will be ready for Publication next Saturday.

RECOLLECTIONS OF JOHN CLAUDIUS LOUDON.

BY NOEL HUMPHREYS.

(Continued from Vol. I., p. 698.)

LOUDON, when he first arrived in London, was much struck with the opportunity afforded by our spacious squares for enlivening, with the aspect of fresh green leaves, the dingy expanse of London houses, then nearly all built of brick, and blackened by the perpetual action of the coal smoke emitted by hundreds of thousands of chimneys. He perceived, however, that our squares were not made to enliven the murky aspect of the great wilderness of bricks and mortar, as they might have done; but almost the contrary, in consequence of a mistaken notion of their planters, that evergreens would be just the thing for the London squares, in order to insure a continuation of "verdure" through the winter. But the evergreens, as our young Scotch horticulturist found to his extreme disgust, had become permanently "nevergreens." The dingy-looking trees which he found struggling through a black and miserable half-existence, consisted chiefly of Scotch pines, yews, and spruce firs; all of which being exceedingly well calculated to receive and preserve the daily and nightly deposits of soot, without the power of renewing their foliage every spring, like deciduous trees, were evidently the very worst kind of plants that could possibly have been selected for the London atmosphere. This ignorant abuse of a fine opportunity woke up the young landscape gardener's indignation, and he dashed into print. Before the close of the first year of his residence in London (1803) he published an article in a periodical called the *Literary Journal*, which he entitled, "Observations on Laying out the Public Squares of London." The main gist of the article consisted in an uncompromising denunciation of the prevailing system, and in strongly recommending the plentiful introduction of deciduous trees, the foliage of which, renewed with the coming of each successive spring, would, as he remarked, secure a cheerful aspect to the squares for some seven months or so of each year. He particularly named the Oriental and Occidental planes, the sycamore, and the almond, as ornamental trees that would bear the smoke of the great city with comparatively small injury; and it is interesting to find how quickly his suggestions were adopted, and to note that there is scarcely a square in London in which planes are not found whose growth evidently dates from about that period or shortly after; and the same may be said of other trees which he named; while the yews, the Scotch pines, and the spruce firs have entirely disappeared.

It was about this time that he became a member of the Linnean Society, and it was also in the summer of 1803, according to a note in his journal, that he first conceived the idea of trying the effects of charcoal on vegetation; the thought having occurred to him in consequence of noticing the beautiful verdure of the young grass that sprung up all over a small space where charcoal had been burned.

In 1804, having been commissioned by Lord Mansfield to make some plans for altering the palace gardens at Scone, Perthshire, he returned to Scotland, and remained there for several

months, during which period he laid out grounds for several gentlemen in different parts of the country. The instructions he found it necessary to communicate to gardeners, foresters, and others, on the planting and management of woods, during the carrying out of the various works he was then engaged upon, and also during many extensive arrangements for draining, and otherwise improving several of the estates in question, led him to make a series of detailed and important notes, which he soon afterwards embodied in a book, which was published in Edinburgh by Constable & Co., and in London by Longmans & Co. This was the first work which Mr. Loudon presented to the public through the great firm of Longmans & Co., with whom he continued to transact business for nearly forty years. The book alluded to was entitled, "Observations on the Formation and Management of Useful and Ornamental Plantations; on the Theory and Practice of Landscape Gardening; and on Gaining and Embanking Land from Rivers or the Sea."

This was his first important work, and contained so many new ideas, explained in such a practical fashion, and at the same time combining with those practical views the power of expressing such noble sympathies with the beauties of nature, that the work met with considerable encouragement, and attracted the attention of many great landowners to the young horticulturist, who had not only the boldness thus to rush into print, but the evident capability of imparting a mass of useful and, up to that time, little known information on the subjects of which he treated. Of the poetical feelings which he mingled with the practical, the following extracts from the introduction will afford a fair idea. They are scarcely equal to similar passages in his later books; but as occurring in his first serious work, they may be advantageously introduced in this place, as samples of his earlier style:—

"Various are the vegetable productions which this earth affords. Blades of grass spring up everywhere, and clothe the surface with pasture; groups of shrubs arise in some places, and diversify this uniform covering; but trees are the most striking objects that adorn the face of inanimate nature. If we imagine for a moment that the surface of Europe were totally divested of wood, what would be our sensations on viewing its appearance? Without this accompaniment, hills and valleys, rivers and lakes, rocks and cataracts—all of themselves the most perfect that could be imagined—would present an aspect bleak, savage, and uninteresting. But, let the mountains be covered with wood, and the water shaded by trees, and the scene is instantly changed: what was before cold and barren, is now rich, noble, and full of variety. In travelling through a naked country, a whole unvaried horizon is comprehended by the eye with a single glance; its surface is totally destitute of intricacy to excite curiosity and fix attention; and both the eye and the mind are kept in a state of perpetual weariness and fatigue. But, in a wooded country, the scene is continually changing; the trees form a varied boundary to everything around, and enter into numberless and pleasing combinations with all other objects; the eye is relieved without distraction, and the mind fully engaged without fatigue. If we examine even a tree by itself, the intricate formation and disposition of its boughs, sprays, and leaves, its varied form, beautiful tints, and diversity of light and shade, make it far surpass every other object; and, notwithstanding this multiplicity of separate parts, its general effect is simple and grand."

The book contains, among other valuable matter, a number of acute observations on the distinctive characteristics of trees and shrubs, plainly showing how carefully and completely he had studied his subject even at that early period of his life, and how fully capable he was even at the age of one-and-twenty of undertaking and carrying out horticultural works of the most important kind. Before leaving Edinburgh in 1805, he published another work, entitled, "A Short Treatise on some Improvements lately made in Hothouses."

On his second visit to London, he was compelled by stress of weather to land at Lowestoft, on the coast of Norfolk, and he had suffered so much during the voyage, that he then determined never again to travel by sea where there was a possibility of going by land. On his return to England he at once resumed his labours as a landscape gardener, and his journal of that period is filled with innumerable notes founded on the ideas which suggested themselves to his ever-active mind during the progress of the various works upon which he became immediately employed. Among the most remarkable are his theories on the best

system of harmonizing the effects of colour in flower gardens. He arrived at the following general conclusions, which, though founded only on observations and an instinctive fine taste for colour, accord perfectly well with the more recent scientific discoveries on the affinities of colours, and of those which are necessarily complementary in regard to others. For instance, he asserts in these interesting notes, that he invariably found, while studying the best effects in gardens, that when flowers were so arranged as to have a plant bearing flowers of a compound colour placed next to a plant bearing flowers of a simple colour, which contained neither of the colours forming the compound one, that the best effects were produced. Thus, as there are only three simple colours—blue, red, and yellow—he advised that purple flowers, which are composed of blue and red, should have yellow next to them; and that orange flowers, which are composed of red and yellow, should be contrasted with blue; and that greenish flowers, which are composed of blue and yellow, should be relieved by red. Many years afterwards (1839) he was much delighted to find that M. Chevreul, the director of the famous manufacture of Gobelin tapestry, in his celebrated work, entitled “De la Loi du Contraste Simultané des Couleurs,” took precisely the same basis for the erection of his vast superstructure, which is the most exhaustive treatise on the nature of the contrasts and complements of colours that has hitherto appeared.

About the same time, that is in 1805, young Loudon formed the ambitious project, in part founded on his theory of colours, of publishing a pictorial dictionary, which was to embrace every kind of subject in which the treatment of colours, formed a part; but the scheme was never realised. In the following year (1806), though constantly employed in planning and laying out grounds, he yet found time to write his “Treatise on Forming, Improving, and Managing Country Residences; and on the Choice of Situations Appropriate to every Class of Purchasers: with an Appendix, containing an Inquiry into the Utility and Merits of Mr. Repton’s Mode of showing Effects by Slides and Sketches; and Strictures on his Opinions and Practice in Landscape Gardening; illustrated by Descriptions of Scenery and Buildings, by Reference to Country Seats and Passages of Country in most parts of Great Britain; and by thirty-two Engravings.” The work was the most bulky and important, as it was the most costly, he had as yet published. The illustrative engravings were careful reproductions of really excellent drawings executed by himself, which were afterwards republished, with short descriptions, as a separate work. At the time I knew Mr. Loudon, many years afterwards, he still preserved a set of proof impressions of this series of engravings, which he was fond of exhibiting to intimate friends as reproductions of drawings which he had made before his right hand became so crippled as to prevent his indulgence in the manual use of pen or pencil for the whole remainder of his life; a deprivation which he felt most keenly and unceasingly, and yet with that placid resignation which was one of the most distinctive traits of his character.

(To be continued.)

Royal Parks’ Act.—On Saturday the Act for the regulation of the Royal parks and gardens was printed. The object of the statute is to protect from injury the places under the management of the Commissioners of Works and Public Buildings, and to secure the public from molestation and annoyance while enjoying the same. A schedule contains the regulations to be observed, and the powers conferred are not in derogation of any other statute. Among the twenty regulations is the following:—“No person shall deliver, or invite any person to deliver, any public address in a park, except in accordance with the rules of the park.” In a second schedule the following parks are referred to:—Hyde Park, St. James’s Park, the Green Park, Kensington Gardens, Parliament Square Gardens, Regent’s Park, Kennington Park, Primrose Park, Victoria Park, Battersea Park, Greenwich Park, Kew Gardens, Hampton Court Park, Richmond Park and Green, Bushey Park, Holyrood Park, and Linlithgow Park. By one of the provisions for appointing a park-keeper, a person may be fined a sum not exceeding twenty pounds, or be imprisoned for a term not exceeding six months, with or without hard labour.

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM JUNE 27TH TO JULY 3RD, INCLUSIVE.)

BY OUR OWN REPORTERS.

Achillea biserrata filipendula incisa Millefolium rosea mollis	Dianthus serotinus Digitalis eriostachys fulva lanata sibirica	Lilium Brownii excelsum fulgens and vars. giganteum longiflorum philadelphicum Thunbergianum and vars.	Pyrethrum achilleae-folium alpinum Balsamita Robinia viscosa Rudbeckia californica triloba Salvia Æthiopis sylvestris Sanguisorba dodecandra Santolina rosmarifolia Scutellaria orientalis Scyphantus elagans Sedum arropetalum Gmelini Senecio Doronicum Sempervivum acuminatum heterotrichum Mettenianum Serratula polyclonis Seseli elatum Sida malvaeflora Silene fruticosa Solidago canadensis rigida Spartium junceum Spiraea callosa corymbosa Douglasii laucolata nutans venusta Stenactis annua Tanacetum vulgare crispum Tetragonolobus biflorus purpureus Teucrium pyrenaicum Thymus vulgaris varie- gatus Trifolium pannicum Tropaeolum majus Urospermum Arnopogon Veratrum nigrum Verbascum Blattaria Chaixii longifolium pulverulentum Veronica Andersonii neglecta Vicia Crucetorum sylvatica Yucca recurva

Plants in this list are almost without exception such as have come into bloom during the past week.

New Park for Leeds.—Roundhay Park is at last secured for the inhabitants of Leeds. Much must be done to it, however, to render it fit to receive the vast crowds who will flock to it. Plans have, we believe, already been prepared for the laying out of new walks and drives, and we trust that care will be taken, in carrying them out, to preserve unimpaired the natural beauty of the park. If the people of Leeds are to have a really beautiful suburb at Roundhay, good taste must be shown in the character of the houses to be built on the fringe of land on its outskirts.

THE GARDEN IN THE HOUSE.

MARANTAS.

The following engraving of *Maranta fasciata* illustrates one of the very handsomest fine-foliaged plants in our collections. Its green leaves, banded with white from the midrib to each margin, characterise it as peculiarly suitable for the decoration of vases. *Maranta roseo-picta* is of more recent introduction, and is noticeable for its rosy midrib and for the similarly-coloured bands upon the leaf a little way from the margin.

Maranta fasciata.

We have often been struck with the absurdity of the forms of vases into which some people delight to thrust the flower-pots in which their favourite plants have been grown. And as our illustrations of the right path and the wrong path in the matter of building up rockwork have, as we are informed,

Maranta roseo-picta.

helped materially to a clear comprehension of what should be done and what avoided, so we venture to hope that the annexed engravings will direct attention to what is good taste, and what is not good taste, in the matter of plant vases. In the vase which holds *Maranta roseo-picta*, there is a chasteness and a beauty of outline which cannot fail to please, combined with a solidity which harmonises well with the style of the

plant. The vase which contains the plant of *Maranta fasciata*, on the contrary, consists of a clumsy heavy saucer, partly supported by a thick piece of stick, and partly by the tail of a pig-headed, or pug-headed fish, which is gracefully reclining his snout and two out of his four ears upon a raised cushion. Such a zoological monstrosity may be amusing to some people, who may also find something to laugh at in the anatomical impossibility of any fish or fish-shaped creature standing upon its head and supporting a heavy weight on its tail; not to mention its double allowance of aural appendages; but we doubt if it would be possible to suggest any form of vase more out of character with the beautiful plant which it contains than this particular vase must appear to the eye of good taste.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 710, Vol. I.)

TRANSPLANTING.

THE best season for transplanting is when the plants are about to pass from a state of rest into a condition of fresh growth, that is, early in spring. Another favourable time is at the end of the first growth in spring, and before the plants (as is the case with many evergreens, such as Camellias, Azaleas, &c.) commence to form the buds for the following year. Transplanting at the time when the plant is in full growth should be avoided, as it disturbs the growth of the plant, and the young shoots are frequently injured, and sometimes quite destroyed. It is only to be recommended when individual specimens of speedy growth are grown for exhibition, and for this purpose are transplanted several times in the course of the summer. Transplanting in autumn is especially to be avoided in the case of room plants, as the new soil does not become filled with roots during the winter, and, in consequence, becomes sour and spoiled; and, if not watered with great care the plants will become sickly, or perish completely. There are a few exceptions to this; as, for instance, bulbous plants, which are kept dry late in summer, and are intended for winter blooming, and some other plants which are to be forced in winter. We would specially remark that the results of forcing will be so much the more certain, the earlier this transplanting takes place, in autumn or late summer.

In the common practice of transplanting, fine healthy specimens are sought to be raised in pots which are proportionately not too large. Plants which have their ball only so far filled with roots that a few small ones reach the side of the pot, should not be transplanted so long as these roots are healthy, and the soil of the ball is fresh, and does not give out a sour smell; which, as we have seen before, is the result of an unhealthy and injurious condition.

Where the soil is spoiled, or the young roots are unhealthy, or, as is frequently the case in good culture, the entire ball becomes so full of roots that it seems to be thickly covered with threads, the plants should be transplanted. Therefore, before proceeding to transplant, the condition of the ball should be examined. This should be done very carefully, so that, in case no change is necessary, the ball may be replaced in the pot without injury. With small plants this examination is best effected in the following manner:—The left hand is spread over the top of the pot, allowing the stem of the plant to come between the fingers. The pot is then taken in the right hand and reversed. The edge is then carefully struck against the corner of a table or board, so as to loosen the pot from the ball; the pot is then lifted off and the ball examined. In the case of larger plants, the soil is first of all allowed to become somewhat dry, then the plant is seized by the lower part of the stem and lifted along with the pot. The pot is gently struck on the rim with the hand or a piece of wood, and so carefully separated from the plant. When a ball filled with roots will not readily separate from the pot, a knife should be passed round the edge as deep as it will go; this will greatly facilitate the operation.

Lastly, plants in large wooden tubs or boxes should only be transplanted when an examination of the ball from above shows that transplanting is absolutely necessary. The vessels

are removed either by taking off the hoops of the tubs, or by taking the boxes to pieces, or else by first passing a long knife round the ball to loosen it, and then turning the vessel on its side and carefully drawing out the plant. After the ball has been carefully removed it should be reduced in size, by removing the spoiled and exhausted soil, in order to give the plant as much fresh good soil as possible, without having to place it in too large a pot or other vessel, which, especially in room-culture, would be very inconvenient. For this purpose the earth round the ball is loosened by means of a sharp-pointed stick, and is shaken out from the roots, so that the ball may be rounded above and below, and its diameter reduced to three-fourths or two-thirds of its former size. If there is an underlayer of potsherds, &c., it must be entirely removed. The roots should then be trimmed round with a sharp knife. In sickly plants the roots will be more or less decayed in parts. These parts must be cut back until sound wood is reached. The roots of healthy plants should not be cut when the plant is in a state of active growth; in which condition, or when it is known that the plant will be injured by a severe root-pruning, it will be sufficient to take away some of the upper soil, to remove the layer of potsherds, to loosen the surface of the ball, and to trim a few of the longest roots a little.

In planting, a pot should be selected so large that, according to the strong or feeble root-forming powers of the plant, there may be around the ball a layer of fresh earth from one-third of an inch to one inch thick. A piece of potsherd, arched in shape, should then be placed over the drainage-hole, so as to cover it well above, but leaving space at the sides for the flow of water. Then should follow a layer of broken potsherds from half an inch to one inch thick, and over this a thin layer of moss to prevent the soil being carried among the sherds. Instead of the layer of potsherds, a layer of moss or of coarse sand may be used, or some of the coarse fibrous tufts which remain in the sieve when soil is sifted. Attention in providing good drainage will be always repaid by the healthy condition of the plants which it secures, especially if they are sometimes carelessly and immoderately watered. After the drainage layer has been put in, just so much soil should be placed upon it that when the ball is laid in, the uppermost roots will be from about one-third of an inch to half an inch below the top of the rim of the pot, so that when the soil is filled in, there may be sufficient space left to retain the water in watering. The ball being so placed that the plant may stand exactly in the centre of the pot, the soil should then be filled in. This should be dry, so that when closely pressed it will not become cloddy. During the gradual filling-in of the soil, the pot should be repeatedly shaken, so that the soil may be evenly settled all round. In small pots it will be sufficient after the soil is filled in to press it down close with the thumb. In pots more than five inches high, especially when the space between the pot and the ball is only limited, the soil should be pressed in during the process of filling in, with a flat blunt piece of wood, so that it may lie evenly in all parts. When the soil is moist and stiff it should not be pressed so closely. The common rule is that a well-potted plant, if the pot is not disproportionately large, may be lifted up by the stem along with the pot without the pot falling off. This experiment should not be tried with weak plants, as they could not sustain the weight of the pot, and would break off, especially if the soil was stiff and moist and the pot rather heavy.

After filling in with just so much soil that the upper roots will be covered, it is to be pressed round the rim of the pot, so that the flow of the water may be directed towards the ball, and not pass through without wetting it thoroughly. When it is desired to raise fine strong specimens quickly, the roots of the plants should not be trimmed more in transplanting, than will allow them to draw sufficient nutriment from the soil in the pot for a strong growth. Two modes of treatment are in use, viz., a single transplanting, and transplanting several times. Single transplanting in pot culture is similar to that practised in open-air culture. It is generally employed in the case of young healthy plants of quick growth, which have not been long raised from seeds or cuttings. When they are transplanted in spring, they are put into pots from twice to four times the diameter of those in which they have previously grown. The old ball is not

disturbed, only the roots which come through it are loosened and spread out in the fresh soil, which should not be pressed down so closely as in ordinary transplanting, as it will be quite sufficient to shake the pot frequently and then press the soil down gently with the thumb. A deep layer of potsherds and moss for drainage, is, in this case (where at the same time a great deal of nutriment is given, and the soil changed only once in the year), very conducive to successful results.

Frequent transplanting effects the same purpose in a different manner. Here also the ball is not disturbed at the time of transplanting, but the pot should be only two or three inches larger in diameter than the pot from which the plant is removed. The soil also, when filled in, should not be pressed down so much as in ordinary transplanting, and the means of good drainage must not be neglected. If a strong growth sets in, the ball must be examined from time to time by carefully inverting the pot. As soon as the ball is quite filled and surrounded by the new roots, the plant must be transferred to a larger pot. A strong and fast-growing plant may, in this manner, be transplanted from two to four times between spring and the beginning of August; after which time further transplanting must be avoided, as such plants endure the winter with greater difficulty and suffer more in proportion as the ball is scantily filled and penetrated with roots.

Of these two methods of raising strong specimens we would, for room-culture, recommend the latter, for the following reasons:—

1. In a room only a few plants can be devoted to this purpose, as they require a good, open position near the window, where, of course, there will not be room for many large specimens. The trouble of frequently transplanting these few will not, therefore, be great.

2. All plants do not bear the change into comparatively very large pots well, but there are some which, when so planted, in spite of all care in watering and drainage, become sickly instead of strong. As an example, we may name the Coffee-tree (one of our most durable room plants), the seedlings of which will bear a tolerably large pot; while plants of the same, raised from cuttings, when transplanted into too large a pot, soon become very much deteriorated in appearance. *Dracæna Jacquinii* and *D. marginata* do not succeed well in large pots, while the other species of *Dracæna* thrive very well in them. Therefore, as the amateur is liable to make mistakes in his selection of plants for this purpose, frequent transplanting affords a means of remedying his errors in this respect, as by often examining the balls he can ascertain to what extent new roots have been formed, and so whether the plants require removal into larger pots or not.

3. By frequent transplanting, the treatment of the plants with regard to watering is much simplified.

4. Small plants in large pots do not look well, and therefore are not suited for room-decoration. The system of single transplanting affords no remedy for this.

Special modes of transplanting are not employed in ordinary room-culture. But in glazed cases and double windows a different method is used, especially in the case of Epiphytes. With these, whether grown in pots, vases, or baskets, the soil must not be closely pressed down, but should be left very loose. All the interstices should be stopped with sphagnum, laid on inside the pots, and the soil should be a mixture of chopped moss, pieces of decayed wood, and coarse fibrous heath soil or peat. Where these plants are only grown on wood, a layer of moss should be fastened on with thread or wire; or if they are plants which, like many of the *Bromelia* family, have been previously grown in pots, the ball should first be wrapped round with moss, and then fastened on to the wood. In this way, in glazed cases, a dead branch here and there is furnished in a picturesque manner with such plants.

Lastly, we have to mention top dressing, which sometimes (especially in the case of plants grown in tubs and boxes, and which, therefore, are more difficult to transplant) takes the place of transplanting. In this operation the soil on the upper part of the ball is loosened by means of a pointed stick; and, after the soil so loosened is removed, the soil at the sides of the vessel is loosened in the same manner to as great a depth as possible, and also removed. The longest of the roots which are thus laid bare are then trimmed, and suitable fresh soil is

filled into the place of that which was taken out. Care should be taken not to fill in the fresh soil any higher than just to cover the uppermost roots of the ball, as, when the upper part of the ball is not well filled with roots, an immoderate degree of dryness is apt to be produced there, which may induce the amateur to give water at a time when it would be very hurtful to the plant.—*Dr. Regel.*

(To be continued.)

ASPECTS OF VEGETATION.

MADAGASCAR.

SOME of the aspects of vegetation in Madagascar are of so peculiar a character that it may be worth while to allude to them again. Of the growth of *Angræcum superbum* on *Strichnos* trees we have already given an account (see p. 509). Another species of the same genus, viz., *A. sesquipedale*, is also parasitical on trees in Madagascar. The Rev. Mr. Ellis says:—"On more than one occasion I found this singular Orchid growing splendidly on the trunks of decaying or fallen trees, as shown in the accompanying engraving, and sending its tough roots down the trunk to the moist parts of the vegetation on the ground. I found one decaying tree of large size lying on the ground almost overgrown with grass and ferns, on the rotten trunk of which *A. sesquipedale* was growing most luxuriantly. The roots, which had penetrated the soft trunk of this dead tree, were white and fleshy, while the leaves were of unusual length, and comparatively soft and green. There were, however," he adds, "neither flowers nor flower-stalks on any of the plants growing in the rich vegetable mould furnished by this old dead tree."

As regards *Angræcums* found on the ground, Mr. Ellis says the finest were to be seen growing near the roots of leafless bushes, and having their own roots surrounded by long green grass. The bushes themselves were growing in loose sand. The very healthy state of these plants tended to induce a belief that a moderate amount of shade and moisture suits them better than the dry exposed branches or trunks of dead trees, on which they are so often found growing.

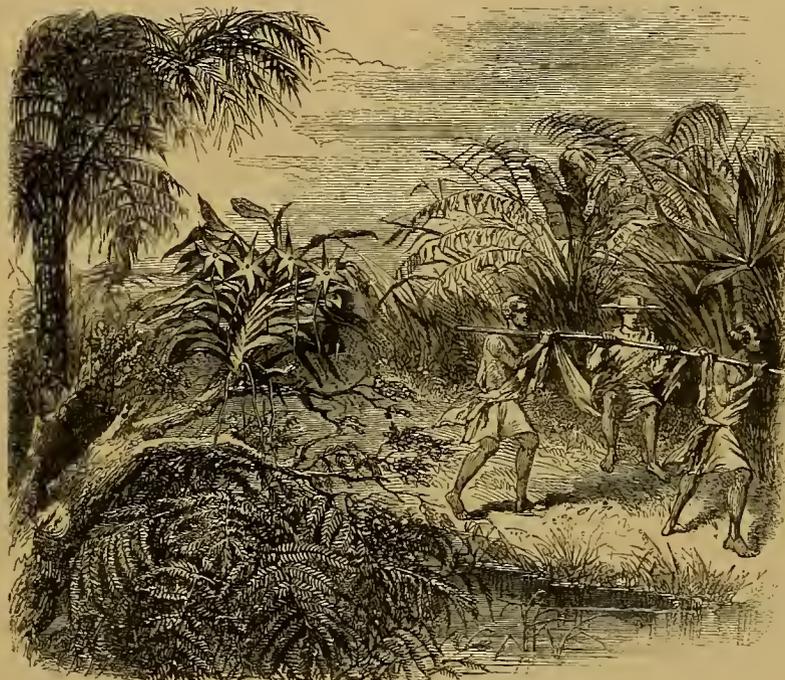

The yellow-flowered *Angræcum crassum* and *A. citratum* were also found by Mr. Ellis in Madagascar, as well as many other interesting Orchids and other plants. "Amongst the latter," he says, "my attention was arrested by a new species of *Pandanus*, with dwarf stalks and broad pointed leaves. Amongst the varieties of indigo, a plant with a pink or red flower was unusually attractive; while a little modest blue *Tradescantia*, somewhat resembling the wild forget-me-not, enlivened the borders of the path. But the greatest rarity was a kind of large-growing heath, with pink or lilac-coloured flowers. In some places I also saw large masses of creeping ferns entirely encircling the trees. The greater part of the

road, however, had been over sandy plains, traversed by ridges or high banks of sand, which had at one time been the boundary of the sea. We also passed through regions of dead, blanched, barkless forest trees, still standing; the only signs of life amongst them being a few orchids or ferns growing in the forks of their trunks and branches. Sometimes we passed through a tract of thick verdant forest of large timber; but in general there were ponds or stagnant marshes, on both sides of the path, sometimes overgrown with long grass or rushes. Along the borders of the running streams, I saw numbers of the tropical lettuce, *Pistia Stratiotes*, growing very freely."

GARDENS AT RAILWAY STATIONS.

BY JAMES M'NAB.

OF late years a great improvement has been effected in reference to these, and I am glad to observe that the taste for station embellishment is greatly on the increase, as we now see one railway vieing with another for this laudable end. Almost all the extra decoration is due to the horticultural taste of the station-master or those under him. I do not quite agree with all the freaks exhibited on roadside stations; still, such freaks in the meantime ought not to be objected to, as they often lead to other and better suggestions. When we consider the great diversity in the tastes and ideas of those for whose gratification they are chiefly intended, allowance must be made by the public for the primitive notions which are displayed in some of them. The great diversity in localities and soils where intermediate stations have to be placed, must in many instances call forth a great amount of ingenuity from those in charge, so as to turn them to the best account. It is to be hoped that railway directors will

Angræcum sesquipedale, as seen in Madagascar.

encourage station gardens as much as possible. In all new-formed stations the *employés* would do well to examine as many as they can, and select the good points of each. Some are, perhaps, too much hampered for room, and in some we find a wall of rock rising almost perpendicularly on each side. Such stations have charms unseen, and, in the hands of a skilful garden architect, could be made to assume forms at once interesting and characteristic of the district. Such schemes would take years to accomplish, but as stones are always in demand, no matter of what kind, their gradual removal would always be facilitating the end in view. Many of these stations, where the rocks are not excessively high, could have the materials removed down to the surface level for 70, 80, or 100 feet in breadth, till the time arrived for their final arrangement. Instead of upright rocky walls, having a narrow platform and the rails between, where the sun rarely penetrates, we ought to see sloping rocky banks, made as irregular as it is possible to work them. The hollow places formed could be filled with soil, to be planted with coniferæ or shrubs and flowers suitable for rocky places. It is greatly to be desired that civil engineers will consider all these hints when designing new station buildings.

In the station building department a great improvement has of late been effected, but much still remains to be done. Any one travelling over the kingdom cannot fail to observe the comfortable-looking

stations on many of the English lines, where brick and white stone are employed, and surrounded by well-kept grass and shrubs. If a little more ground could be allowed round some of the Scottish stations, they would soon be able to vie with the English in every respect. When the train comes to a standstill, it is certainly pleasant to cast the eyes on these delightful spots, particularly after a weary run of many miles, and then rest contented till arriving at another station. By a continued improvement of the kind suggested, delicate eyes may be kept at rest, knowing that something more pleasing is in store for them at the next stopping-place, instead of straining them on tree stems and telegraph posts.

THE FRUIT GARDEN.

PACKING FRUIT.

IN these days, when a large portion of the produce of the garden has to be sent by rail, the question of packing is one of no little importance. Having had some experience in packing fruits, flowers, and vegetables for travelling long distances, I propose to say a few words on the subject.

The fruit which is generally wanted in greatest quantity, and which bears carriage worse than almost any other, is the strawberry; and some varieties, however, stand carriage better than others, and among these I may mention British Queen, the Pines, Prince of Wales, Sir Harry, and others. Still, I have packed all sorts for many years; and, as a rule, they arrive in London in very good condition. The tin boxes we use for this purpose are one foot square, and from one and a half inch to two inches deep. When about to be filled, a thin sheet of cotton wadding is laid on the bottom of the box, and on this a layer of soft vine leaves. The berries are then laid hold of by the footstalks, and laid in one by one, as nearly on their hase as the footstalks will permit; a soft strawberry leaf is laid between each berry, and they are wedged together as tightly as can be done without actual crushing. When all have been laid in they are covered evenly over with strawberry leaves, and another sheet of cotton wadding (sufficient with the leaves to hold all firmly in their places) is laid on the top, and the lid shut down and secured. The condition of the leaves for putting between the berries is of some importance. No leaves of any kind are fit for this purpose when just pulled; they are then too hard, and do much injury. For this reason we have the strawberry leaves pulled the night before and strewed over the fruit-room table; by morning they are limp and flaccid, and can be used with safety. It is a common practice to wrap each berry in a leaf; but it is not a good plan, for the less the fruit is handled the better; and the plan of laying a soft leaf between each fruit, as I have described, does away with the necessity of handling the berries at all except by the footstalks.

As regards peaches they require as much care in gathering as in packing, for the slightest bruise will appear an ugly blemish a few hours afterwards. Have a tray lined with a thick layer of wadding beside you when going over the trees; try only those that look ripe, and, taking the peach gently in the palm of your hand, bring the fingers and thumb under its hase, and if it does not come away with a slight effort leave it. What are ready, set on the tray, and do not handle them again till they are packed. Some have their peach boxes divided into compartments about four inches square; but it is not an economical plan, for only one peach, be it large or small, can be put into a division, and they are too often bruised in getting them out again. The boxes should be of tin, and from twelve to eighteen inches square, and four and a half inches deep. In packing lay a thick piece of wadding on the bottom, and line also the sides; then take a square piece of wadding of the requisite size, lay upon it a piece of the softest tissue paper, and on this set the peach; fold the wadding up over it, and set it on its base in the box at one corner. Fold up the others in the same manner, pack them closely together, lay a sheet of thick wadding on the top, shut and fasten the lid securely, and they are safe from any ordinary danger.

Few fruits bear carriage better than grapes, and yet, strange to say, they are often much damaged in their transit, for the simple reason that they are seldom packed as firmly as they ought to be, through fear of crushing them, though the grape will stand a wonderful amount of pressure before breaking, and the bunches have a certain elasticity about them which protects them. Boxes eighteen inches by one foot, and six inches deep, are a convenient size. We use soft paper shavings or wadding for packing them, first wrapping the bunches in soft drapery or tissue paper, and twisting it at each end; they are then wedged together with a few shavings between the bunches, and a layer below and above all, in sufficient quantity to hold them securely in their places, when the lid is put on. All

our packing materials are returned in due course, and it is seldom that there is the slightest stain from a broken berry on the grape papers. Nor does the bloom suffer to any serious extent by this mode of packing, if done with ordinary care. It is friction which rubs the bloom off most, but firm packing prevents this to a great extent.

Figs are precarious things to handle in packing if perfectly ripe, as all figs ought to be before they are sent to table. Their skin rubs off with the slightest touch. They should be detached from the tree with great care, and they should be packed like peaches; but, instead of using tissue paper inside the wadding, use a soft vine leaf in a flaccid state and fold the fruit carefully in it, and pack tightly, using plenty of wadding.

Raspberries when sent for dessert are packed like strawberries. Other small fruits, such as currants, gooseberries, and cherries, will travel well without packing further than a layer of leaves top and bottom. Plums will travel well in a bed of soft, clean leaves, and covered with the same, but the bloom of the fruit is easily rubbed off. It is a common plan, and a good one, to pack the different boxes of fruit in one hamper when sent off. Sometimes they can be sent in the vegetable hamper. Either way, do not let the hampers be unwieldy and inconvenient to handle, and the chances are that the damage, if any, will be less than it otherwise would be. J. S.

THE MARKET-GARDEN STRAWBERRY STRIKE.

A GREENGROCER'S life just now, says the *Telegraph*, must be rather too exciting to be pleasant. Vegetables are daily advancing in price, and the indignant remonstrances of *Materfamilias* intensify with every new rise. The meek purveyor of vegetables would never finish his daily course had he to explain at every house door the roundabout circumstances which have occasioned so unseasonable a dearth of garden produce. Were purchasers to be dropped down for half an hour in the rural lanes of Fulham, the mystery would be explained to them in a trice. Any of these corduroy-trousered men with their hands deep in their pockets, and a sad kind of scowl on their faces, would prove voluble on the subject. They are market gardeners on strike, and very melancholy they do look, prowling about on the wrong side of the hedge. They have been executing that penitential promenade for fully a fortnight, and as yet they don't see how or when it is to end.

Fulham has suffered from similar insubordination once before; on that occasion it succeeded, and the matters in dispute were comfortably settled. And so they have gone on till about three weeks ago, when the word was passed that on the following Thursday the men in each garden should wait upon the masters, and intimate that after Saturday night a halfpenny an hour more would be wanted. The scheme was carried out with entire unanimity, and on the Monday morning every garden in the district was deserted. The masters had peremptorily refused any rise, or any entertainment of the question. Some of the men crossed the river to Barnes, and sought employment there; but a hint had preceded them from Fulham, and Barnes would receive no firebrands. This "blackballing" was viewed with bitter resentment. A few single men packed up their goods and crossed the Channel to Ireland; but the majority, being married, chose to remain at home, lounging about among the lanes. That has been their daily occupation for a fortnight; and all I could observe of them implied that they were doing it very decorously indeed. A master with whom I spoke afterwards admitted the fact of their good behaviour, but transferred the credit from the men themselves to the police—of whom, during the afternoon, I saw two.

Covent Garden had to be supplied from these deserted lettuce-grounds and strawberry-beds. Cauliflowers and radishes were at their best. All garden produce was at a premium, and the masters had to get it taken off the ground somehow. In some cases they buckled to the work themselves. After a day or two they managed to beat up a small troop of boys and girls in the village. All the while agents were scouring the adjacent districts for men. Last Sunday morning the fine warm weather had brought things to a crisis. Fruit must be picked, and vegetables cut, else they would spoil. Vans and carts were sent into the odorous purlieus of Seven Dials and Drury Lane for the halt, the lame, and the blind. The *sans culottes*—enticed from their reeking courtyards by the promises of a free ride to-and-fro, a warm dinner, as much fruit as they could eat, and a trifle in Queen's coin—turned out in shoals, and made a prosperous journey to Fulham. It was reported on Sunday night that the strike hands assailed their successors with yells and hootings which threatened to end in more violent proceedings. There was even a rumour of incendiarism in connection with a fire which happened at a gardener's house. I questioned my authorities on these reports, and they were profoundly disgusted. The eldest acknowledged that when the vans arrived at Parson's Green there had been

some "hollerin' and hootin'," but the ill-used man interposed that it was only "a bit of amusement loike." The Seven Dialites went peaceably to work, and some of them have been carted out and in daily since. They have taken the place of the women rather than of the men. In one or two gardens male substitutes had been found within the first day or two—farm labourers brought up from the country.

They did not give up hope when they threw down their spades. There were no "agitators" in the district to mount the stump on their behalf; but a more judicious champion came forward in the Vicar of Fulham. Either of his own accord, or at the instance of the Rev. Father Bond, to whose congregation many of the men belonged, he went round among the masters to ascertain their real disposition on the subject. It was unrelenting, however; and the kindly vicar carried back to the priest a discouraging answer. Anticipating another issue, the men had clubbed together a few pence, and got a hand-bill printed, calling a public meeting in the schoolroom at St. Thomas's Church. The bill stated for them "that they most respectfully invite the master-gardeners to attend, pledging themselves to pay them every respect, and assuring them that their only object in calling the meeting is to bring about a peaceful settlement of the differences now existing between them." One master accepted the invitation, and he represented only himself. There were excuses offered afterwards by others, that the men should have known Friday was a very busy night—that they should have given longer notice—and so on. The intended conference was a failure; and Pat is scratching his head about what to do next. Fulham is little else than a market garden, and, except in the brick-fields, he has very little chance of other employment. He is attached to the village, albeit the rent of a couple of rooms for his family costs him more than a fourth of his wages, and like many another householder, he wishes to have the increased price of coals and bread taken into account on his behalf.

In order to test the men's statements, and to be placed on the masters' standpoint, I called on the owner of one of the largest gardens. His tone in speaking of the strike was strikingly akin to that of the Warwickshire farmers in March. They could not pay more wages, he said; and they wouldn't. Some of them would rather give up their gardens first, or turn the plough into them. "Why," he asked, "did they not come forward in a manly way and give us a week's notice? I have heard several people say they will not take back their old bands on any terms. One is selling off his stock and crop now, and means to let his place. In Fulham, where digging has been all done by spade hitherto, we shall have to use the plough, and the men will see what good they have done themselves next winter, when they are told to take fourteen shillings a week, or stay at home." I was surprised, however, at the answer to an inquiry about the quality of Irishmen as labourers. He would not deny that they were first-rate labourers—or at least had been till this summer. They learnt the business very quickly, and they were clever at turning from one kind of work to another. They were particularly suited for a market garden, where they might have to be at half-a-dozen different jobs in the course of a day. Their gravest fault in the eyes of their ex-employer was that they were not vigilant in driving away juvenile trespassers from the lettuces. These labourers—whose occupation implies that they must be more than merely muscular machines, and whose lodging costs them more than a fourth of what they earn—have thrown themselves idle because they want a pound a week to live upon, instead of seventeen shillings and sixpence.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Disabled Peach and Nectarine Trees.—I have some Peach trees which last year made very excellent growth, and which promised to produce a good crop. The bloom was most profuse, but Jack Frost put a stop to my getting any fruit. Then came swarms of aphides, which threatened to take trees and all. Having a liberal supply of Pooley's Tobacco Dust and a distributor at hand, I thoroughly dusted the trees, with a determination to either win or lose. I was successful; now they are thriving grandly, and no other intruders have ventured to attack them. I believe, however, that I should have lost my trees had it not been for this antidote.—THOMAS J. CAPARN, *Newark-on-Trent.*

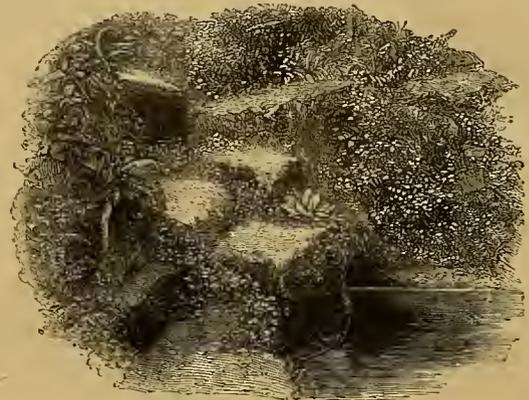

Gooseberry Training and Protection.—I lose nearly all my gooseberries when ripe, from want of some efficient means of protecting them from the birds. Will you kindly tell me how to protect them in the most efficient way? A neighbour of mine trains his in a concise way, and covers each bush with some galvanized wire-netting.—S., *Highgate.*—[A very excellent way of growing the gooseberry, and at the same time protecting it from frost, is to train the shoots on a low trellis, made, say, of three lines of thin galvanized wire, rising three or four feet high. These should be fixed in lines at three feet apart, and the plants placed rather closely, so that the trellis may be covered quickly and well. By this arrangement a net may be stretched over a number of lines with less trouble than would be required to "net" half-a-dozen bushes on the old plan; while the berries may be gathered as readily as if the bushes were not netted at all—the gatherer entering at one end and passing readily between the lines.]

THE FLOWER GARDEN.

THE ALPINE GARDEN.

(Continued from page 606, Volume I.)

In the construction and planting of every kind of rockwork it should be distinctly remembered that every surface may and should be embellished with beautiful plants. Not alone on rocks or slopes, or favourable ledges, or chinks, or miniature valleys, should we see this kind of exquisite plant-life. Numbers of rare mountain species will thrive on the less trodden parts of footways; others, like the two-flowered Violet, seem to

Steps in Alpine Rock-garden.

thrive best of all in the fissures between the rude steps of the rockwork; other dwarf succulents delight in gravel and the hardest soil; others will run wild in any wood or among low shrubs near the rock-garden.

The accompanying figure is from a photograph of the lower part of rude steps ascending abruptly from a deep and moist recess in a rock-garden. It shows very imperfectly—no engraving could show it otherwise—the crowds of lovely plants that gather over it, except where worn bare by feet, thriving year by year as freely as they do on the most favoured spots in the Alps.

It can scarcely be necessary to add that we cannot too carefully avoid any cemented work which would in the least degree interfere with this happy tendency. In cases where the simplest type of rockwork only is attempted, and where there are no steps or rude walks in the rock-garden, the very fringes of the gravel walks may be gracefully enlivened by allowing such plants as the dwarfed Sedums to become established in them. The alpine Linaria is never more beautiful than when self-sown in a gravel walk.

Another very important principle to bear in mind in forming the rock-garden is, that, as a rule, much more vegetation than rocks should be seen. Where vast regions are inhabited by alpine plants, acres of crags with a stain of flower or fern here and there, are very attractive and imposing parts of the picture; but in gardens, where our creations in this way can only be Lilliputian, an entirely different method must be pursued; except in places where great cliffs are naturally exposed and even in this case an abundant drapery of vegetation is desirable. A rockwork is rarely seen in which plants predominate as much as they ought. Frequently masses of stone are met with under this

Alpine Flowers (a Garden Sketch).

name with an occasional tuft of vegetation, every chink and joint between the stones being thus exposed. This should not be so; every minute chink should have its little line of verdure; and in this way we should not only have more plants, but hide the artificial nature of the structure. Where the ground is low and bank-like, there really is not the slightest necessity for placing stones all over the surface; an occasional one cropping up here and there from the mass of vegetation will produce the best effect. Alpine flowers are often seen in multitudes and in their loveliest aspect in some little elevated level spot, frequently without a rock being visible through it, and, if so, merely peeping up here and there. They are lovely too in the desolate wastes of broken rock, where they cower down between the great stones in isolated, lonely-looking tufts; but it is only when Gentians and silvery Cudweeds, and minute white Buttercups, and strange large Violets, and Harebells that waste all their strength in flowers, and fairy Daffodils that droop their heads as gracefully as Snowdrops, are seen, forming a dense turf of living enamelled work, that alpine flowers are seen in their fairest aspects. Fortunately the flowery turf and stony mound

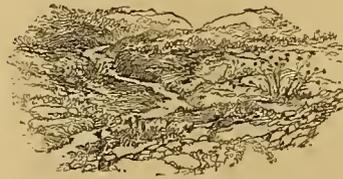

A little Upland Valley in a Rock-garden. (From a photograph.)

are much more possible to us than the bare moraine blocks or arid cliffs. The accompanying illustration is a view of a little elevated stony valley in an artificial rock-garden. Its surface is composed of comparatively large stones, but between them there are chinks leading to deep masses of earth, broken stones, and grit, and from thence issue vigorously tufts of the Moss Campion and other plants, which lap over the hard edges of the stones, and become at all seasons cushions of glistening verdure—in spring and summer of innumerable starry flowers. Stone and plants are seen in about equal proportions, and the effect is of the most pleasing kind.

In cultivating the very rarest and most minute alpine plants, the stony, or partially stony, surface is to be preferred. In their case we cannot allow the struggle for life to have its own relentless way, or we should often have to grieve at finding the *Eritrichium* from the high Alps of Europe overrun and exterminated by a dwarf American Phlox, and similar cases. Perfect exposure is also necessary to complete success with very minute plants, and the stones are very useful in preventing excessive evaporation from their roots. Few people have any conception of the great number of alpine plants that may be grown on the fully exposed level ground as readily as the common Chamomile; but there are, on the other hand, not a few that require some care to establish them, and there are usually new kinds to be added to the collection, which, even if vigorous ones, should be kept apart and under favourable conditions. Therefore, in every place where the culture of alpine plants is entered into with zest, there ought to be a select spot on which to grow the most delicate, most rare, and most diminutive kinds. It should be fully exposed, and while sufficiently elevated to secure perfect drainage and all the effect desirable, should not be riven into miniature peaks or crags or cliffs.

The greatest watchfulness should be exercised over the plants on all such structures as this. They will not perish from cold or heat or wet, if properly planted, but many of them are so minute that they are not capable of affording a full meal to a browsing slug, and accordingly often disap-

pear during a moist night. Now as our gardens abound with slimy creatures that play havoc with many subjects colossal compared with our alpine friends, it is clear that one of the main points is to guard against slugs, and as far as possible against

Water-fence in an Alpine Garden.

worms. Mr. Backhouse has very cleverly fenced off the choicest parts of his rock-work from them by a very irregular little canal, as shown in our illustration. It may be so arranged and cemented that, while not an eyesore, and perfectly water-tight, no slug will cross it. It thus becomes

a much easier task to guard the plants from injury than when they crawl in from all points of the compass. But even with this precaution, it is necessary to search continually for snails and slugs; and in wet weather the choicest parts should be searched over in the evening, or very early in the morning; with a lantern, if at night. Sir Charles Isham, who is an enthusiastic cultivator of rock-plants, says that he not only protects toads, but does not forget to lay stones so as to form little retreats for them underneath. They prefer a stone just sufficiently raised to crawl under, and must do a deal of good by destroying slugs, &c. He also protects frogs and all carnivorous insects. Ceaseless hand-picking is the best remedy for slugs, and where not done, there is little hope of succeeding with many subjects, at least in regions where slugs are as abundant as we usually find them in gardens.

(To be continued.)

ARALIA JAPONICA.

A VALUABLE kind, quite distinct, with undivided, fleshy, dark-green leaves. It is usually treated as a greenhouse plant, but is hardy, and makes a very ornamental and distinct-looking shrub on soils with a dry porous bottom. It grows remarkably well in the dwelling-house; in fact, it is one of the very few plants of like character that will develop their leaves therein in winter. Not difficult to obtain,

Aralia japonica. (After Vilmorin.)

it may be used with advantage in the flower garden or pleasure ground among medium-sized plants—say those not more than a yard high. It would form striking isolated specimens on the turf, and is also very suitable for grouping. It is commonly known in our gardens as *A. Sieboldi*. About London it may be noticed thriving in various districts, as for example, in the Regent's Park, and in the Duke of Buccleugh's garden at Montague House.

Tropæolum polyphyllum.—A hardy species belonging to the tuberous-rooted *Tropæolums*, viz., *T. polyphyllum*, is now an attractive object in some of the London nurseries, notably the Exotic Nursery, Tooting, and the Wellington Nurseries, St. John's Wood. At the first-named establishment it is used as a low wall-plant, where

its showy, pale orange-yellow blooms are so freely produced as to nearly hide the foliage; while at the latter place it is allowed to trail over the ground, a position in which it flowers equally well. It is a capital subject for low trellises, rockwork, low walls, or warm banks, and succeeds best in rich sandy loam.—T. S.

Angry with Exotics.—Since we possess in our own land such a wealth of delicate flowers in harmony with our dispositions, and so subtly interpreting our European nature, why do we roam over the whole earth in quest of decorations for our gardens? Within the last half-century the face of Europe has been changed by the sudden, reckless, and uncontrolled invasion of exotics. The acacia we had before I was born. During my childhood, I witnessed the introduction of the Hydrangea; in my youth, of the dahlia; in my manhood, of the fuchsia, and simultaneously, of a hundred thousand plants. Our parterres, loaded and overloaded, remind one of the heavy, gaily-coloured shawls which have destroyed the genuine Cashmere. The seasons fail in their due effect—their deep and native poetry—because troubled by the unexpected apparitions of strange flowers, which often come at inopportune times, are ignorant of the periods of our year, and, for example, beam gaily and smilingly in the melancholy moods of autumn. The time is wan and pathetic; but the Antipodean flora thinks it is spring, and vexes our souls with its bravery of colour. The eye, nevertheless, accustoms itself to their fantastic conceit, as the ear becomes habituated to brazen instruments; and thus our ruder senses embrutify the soul, for a certain kind of pleasure which is without taste and without memories. Surely, a more artistic age will come, when these intruders shall no longer force themselves upon us, as they now do, with eager and abrupt impertinence. We shall no longer admit a plant without knowing something of its relationships, and even, as far as possible, of all the great local harmonies by which it is circled.—*Jules Michelet.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Podophyllum Emodi.—I shall be glad of any hints as to the culture of this peculiar plant. Also as to when it flowers and fruits.—G. P.—[This plant succeeds perfectly in peaty soil, if planted in warm sheltered spots. In such positions it is a capital subject for the margins of beds of American plants. It may be increased by seed or division.]

Dwarf Rock Harebells.—I am planting an old chalk pit with these pretty plants, and shall be glad if you or any of your readers will give me the names of all the distinct dwarf kinds that are worthy of a place.—Wm. EGINGTON.—[*Campanula cespitosa* and its vars., *carpatica* and vars., *Elatines*, *fragilis* and its vars., *hirsuta*, *garganica*, *isophylla*, *marialis*, *pulla*, *rotundifolia* and its vars., and *turbinata* are all excellent kinds, well adapted for the purpose you require.]

The Corn-Flower (*Centaurea cyanus*).—Few persons seem to have any just idea of the value of this as an early summer plant, when sown in autumn. The variety in the colours of the pretty flowers is quite charming. The blooms are among the best for cutting. Self-sown plants, or those sown in the autumn, make a lovely display on strong soils. No garden in which flowers are valued in the early summer, should be without a mass or a few tufts of it.—W. R.

Eriogonum umbellatum.—I noticed a fine plant of *Eriogonum umbellatum* the other day flowering more profusely than I had hitherto seen it. The plant I allude to was about fifteen inches across, throwing up numerous flower stems six to eight inches high, on which were produced its golden yellow blooms in umbels four inches or more across, forming a neat and conspicuous tuft. This plant I have usually observed flowering very sparsely; but when seen in the fine condition above named, it is worthy of a place on any rockwork or border.—S. W. K.

Solanum jasminoides.—As a wall-climber this is a plant that is not at all sufficiently appreciated; when seen as I have recently seen a specimen on a wall at Kew it is a grand object. There it thrives perfectly, and has lived out and flowered for many years, and has this year produced its pretty white flowers so profusely as to form a very conspicuous object, whether seen at hand or at a distance. It is a native of Chili, and is worthy the attention of anyone who is in need of wall plants; it would also be useful for training up pillars, verandahs, trellises, &c. It likes good sandy loam.—U.

Lasthenia glabrata.—This hardy annual composite has been flowering freely in the Botanic Gardens, Kew for these past two months, and is now a perfect mass of rich orange yellow blossoms. It grows about fifteen inches in height. The plants at Kew are evidently from seeds self-sown last autumn; and where an early summer display is wanted this would form a capital subject if sown in autumn. Patches of it in mixed borders would come in along with early Phloxes, Alyssum, Iberis, Wallflowers, &c.; it certainly far surpasses any of the *Doronicums*, which often find a place in such borders.—T.

Agapanthus umbellatus.—I lately saw at Ravensbourne Park plants of this lovely old-fashioned Lily, that had stood out in the open ground all the winter, and which are now pushing up strongly. The soil is stiff clay; aspect east. I have somewhere read that this plant ought to be allowed to have plenty of light during the winter, but here I saw a fine lot that had been wintered in an ashpit, and I was informed that thus treated they flower profusely every season. This Lily may be wintered successfully under the stage of a greenhouse, or even in a cold pit, and never fails to bloom freely during the summer-time.—J. C.

Rare Alpines at Benthall Hall.—*Cortusa Matthioli*, a rare and valued alpine, sometimes considered difficult to grow, and uncommon, grows perfectly here in a border of sandy peat. The fringe of a bed of American plants suits it admirably. The Lion's-foot cudweed (*Gnaphalium Leontopodium*) also grows well out of doors here in ordinary moist soil. The fine yellow *Anemone palmata*, a superb spring flower, shows itself to be an excellent border plant, its handsome leathery leaves forming large tufts which have flowered freely. The Sikkim primrose (*Primula sikkimensis*) also grows well in beds of peat in this part of Salop.—W. R.

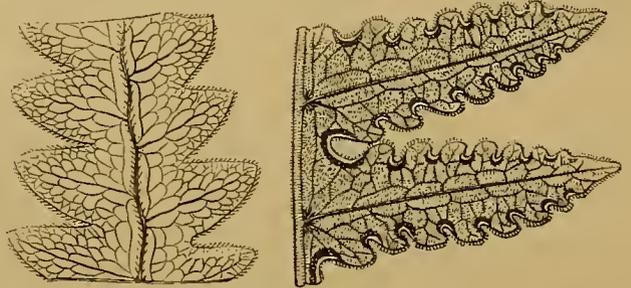

Hardy Palms.—Your illustration (p. 479) of *Chamarops excelsa* leads me to inquire whether there are more hardy Palms than one? I have always understood the plant just alluded to, to be *Chamarops Fortunei*, which in some catalogues is bracketed *excelsa*. In others, and in your descriptive list of Palms, they are distinct. I have also been shown the two in nurseries, and their appearances were very different. As I propose planting some out it is of importance to myself, or anyone similarly inclined, to get the right one. I should therefore be obliged if you would decide this matter for me.—HERR F. [Mr. Croucher and others think that *Chamarops Fortunei* and *excelsa* are distinct; M. Carrière that they are one; and we have never seen any evidence that they are distinct.]

THE LIBRARY.

GARDEN FERNS.*

THE book which we are about to notice is not a very recent work, six years having elapsed since its publication. It is, however, part of the programme which we have laid down for our guidance, to bring before our readers such works as are likely to be of the greatest amount of practical use to them; and, in the present instance, we know of no more recent volume which is superior to Mr. Smith's "Ferns, British and Foreign," as a handbook for cultivators, whether as regards the practical or the scientific knowledge which it contains. That it is not so well-known as it ought to be is evidenced by the requests to recommend a book on ferns which we so frequently receive; and we believe that we shall be doing a service to many in directing their attention to this little volume.

Few authors can lay greater claim to be considered as an authority upon any subject than can be brought forward by Mr. Smith to support the position which he has taken as a writer on ferns. From the year 1822 up to 1864, a lifetime of many men, he has watched and superintended the formation of the now wonderful fern collection at Kew. At the former date he tells us that the entire Kew collection of exotic ferns did not exceed forty species, while, in 1857, in his catalogue of cultivated ferns, five hundred and sixty are enumerated as known in British gardens, most of which were at Kew. "Since the last mentioned year, the constantly increasing demand for ferns, consequent upon their wider cultivation, has greatly stimulated the introduction of new ones, and our collections have increased at the rate of about fifty species a year." The Kew collection dates from 1775, when Francis Masson, "one of the earliest, if not the earliest, collector sent out from Kew, sent home several ferns from the Cape of Good Hope and Madeira." The first introduction of Australian ferns was about 1808, when George Caley (erroneously

Portion of barren and Fertile Fronds (Natural size).

named Alexander in the work before us) was sent by Sir Joshua Banks to New South Wales; "to him we owe *Platyterium alaicorne*, *Doodia aspera*, and *Davallia pyxidata*." The first colonial garden from which ferns were received at Kew was that of Ceylon, from which Mr. Alexander Moen, the then director, sent home a collection of plants, among which was *Nipholobolus costatus*. Singularly few Cape ferns are in our collections, although the fern flora of Southern Africa is extremely rich. Jamaica has supplied more ferns to Kew than any other part of the western hemisphere, a fact mainly due to the energy and perseverance of Mr. Nathaniel Wilson, the island botanist and director of the botanic garden. The West Indian Islands have, indeed, contributed a very large proportion of the tropical ferns now in cultivation, as comparatively few have been received from the continent of America.

Turning to those who have been most prominent in introducing ferns, Messrs. Loddiges, of Hackney, were the earliest to form a collection, although the old-established firm of Lee & Kennedy, of Hammersmith, is recorded in the second edition of the "Hortus Kewensis," as having introduced *Polypodium asplenifolium* and *Asplenium monanthemum* in 1790. But to Messrs. Veitch & Sons, of Exeter and Chelsea, must be assigned the credit of having introduced the greatest number of these plants; the collectors employed by them in Chili and other parts of the American continent, in India, the Malayan continent and islands, and in Japan, having sent home numerous fine species; while through other sources they have obtained many additions from Australia, New Zealand, and other countries.

It would occupy too much of our space did we attempt to enter more fully into the chapter on the introduction of exotic ferns from which the preceding facts are, for the most part, taken. The chapters

* "Ferns, British and Foreign; their History, Organography, Classification, and Enumeration." By John Smith, A.L.S., Ex-Curator of the Royal Botanic Gardens, Kew. London: Robert Hardwicke.

on organography, and the genera, and classification of ferns, will well repay careful perusal. A word, however, must be said as to the figures, by one or more of which each genus is illustrated, and of which we are enabled to give examples; they are in most cases, although small, and of portions only of fronds, sufficiently characteristic, and form an important adjunct to the book. The genera only are described, the species being arranged in groups marked by one or more distinctive features, with details of geographical distribution, and copious references to figures and descriptions. The chapter on cultivation is simply invaluable to every cultivator whether on a small or large scale.

The book, in short, is the work of a man thoroughly conversant with, and enamoured of his subject; and, as a natural consequence of these conditions, it is one which will be of practical use to all who may purchase it.

PUBLIC GARDENS.

THE BOTANIC GARDENS, EDINBURGH.

NOTES BY A VISITOR.

EDINBURGH is, or will soon be, at the height of its tourist season. Already the "one side of the one street" in the town is thronged by strangely-clad and marvellously-battled pleasure-seekers of every civilized nation; and if among the crowds of nomads who annually sojourn in the caravanserais of Princess Street there are any who are—scientifically or unscientifically—fond of trees and flowers, let them not leave the town without visiting the Botanic Gardens in Inverleith Row, for they are worthy of the noble city of which they are a feature. No sooner is the modest gateway entered than the visitor may believe himself to be a hundred miles from the busy city, for he may wander for hours in sunny glades, and find at each turn new objects of beauty and interest, new vistas of bright colour and fresh verdure.

On the upper or northern terrace are situated the palm house and the principal plant houses, which at present are being largely added to, and which contain a splendid collection. These were closed at the time of my visit the other day; but this I hardly regretted, as it left more time for the outdoor part of the gardens. At the back of the range of houses is a long walk, with a wide border upon each side filled with beds of herbaceous plants. Just now the most conspicuous masses of colour there are formed by Delphiniums, *Gladiolus byzantinus*, *Pyrethrums* in great variety and of singular beauty, *Agrostemma coronaria*, whose bright rosy flowers show so well against the glaucous, or hoary foliage, *Lilium monadelphum*, and *Hemerocallis*. The brick wall which forms the northern boundary of the garden is at the back of one of these beds, and supports an interesting collection of climbing plants and trained shrubs. Along the front of the plant houses is a mixed border with some nice plants in it, notably one labelled *Cosmea diversifolia*, with striking flowers. The bank on the south side of the terrace contains beds of American and other flowering plants; below which again is an extensive and well-arranged collection of British plants. The remainder of the northern half, down to where used to be the wall dividing the Botanic from the Experimental garden (which wall is now removed with happy results), is occupied with beds of roses, and beds containing plants arranged in Natural Orders. The most showy of these at present are the *Liliaceæ*, the *Iridaceæ*, from the stately *Iris pallida* to the delicate *sibirica* and the curious *atrorubens*, and the *Saxifragaceæ*. The whole space here is agreeably ornamented with pines and deciduous trees singly and in groups. We now pass the rather shabby little piece of ornamental water, into the old Experimental garden, where there is a large collection of American shrubs and bedding-out plants. Another large plant house, at the back of which, on the south side, is one of the newest and best features of these grounds, namely, the rock-garden. Comparisons are to be avoided as a rule, yet one involuntarily calls to mind the unfortunate constructions which go by the same names in some other botanic gardens. This one is very extensive, and contains an interesting collection of alpine and other hardy plants. It is, perhaps, nay, certainly is, more formal in design than would be desirable in a private garden, as each

species occupies a rectangular compartment and has a label of its own, which necessarily destroys any illusion; but that is probably found necessary in a scientific institution; and for the most part the plants are growing so luxuriantly as to hide the margins of their cages and the labels. The general outline and design of the rockery leave little to be desired.

The most attractive objects on it at present are certainly the magnificent *Saxifrages* in full bloom. There are numerous fine specimens of *S. nepalensis*, *S. Cotyledon*, *S. intacta*, and *S. pyramidalis*; and every flower-lover who is without them, would doubtless on seeing them, determine to be without them no longer. The too-seldom-seen *Delphinium Belladonna* (pale blue larkspur) is also a great ornament to the higher points of rock. Among many gems in full bloom may be noted as rare and desirable *Calochortus luteus*, with beautiful waxy yellow flowers; *Dianthus alpinus*, of which there were several seedling plants; *Epilobium Dodouæi*, a most brilliant dwarf, large-flowering Willow herb, about six or eight inches high; *Myosotis Imperatrice Elizabeth*, a hybrid, apparently of *M. azorica*, of erect habit, and coloured like *Gentiana verna*; *Cheiranthus longiflorus*, a dwarf wallflower, covered with shaded purple and reddish flowers; the lovely *Aquilegia cærulea*, which should be more sought after; *Chrysobactron Hookeri*, with clear, rich yellow spikes; and some very pretty *Babianas*. Many *Sedums* and *Sempervivums* are in, or coming into, flower (note the strangely disproportionate blossoms of the quaint cobweb houseleek, *S. arachnoideum*), and the lovely Indian poppy, *Meconopsis aculeata*, has just passed over.

These notes are sent not as an account of these gardens—may we hope for that some day from a pen that can do them justice, graphically and scientifically—but as a sort of rough-and-ready guide to some of the many visitors who are now in Edinburgh, and who might otherwise feel adrift on entering the grounds, as there appears to be no catalogue or guide obtainable at the lodge.

SALMONICERS.

THE BOTANIC GARDEN, GLASNEVIN.

The Glasnevin Botanic Garden is situated on the north side of Dublin; but in the immediate suburbs, being only two miles from the centre of the city, on the road leading to the Naul, Drogheda, and the northern counties. We learn from the director's "Handbook to the Garden," that it was originally founded, about the year 1790, for promoting scientific knowledge in the various branches of agriculture and planting, as well as for fostering a taste for practical and scientific botany. The first grant for forming the garden was made by the Irish Parliament in that year, and ever since annual sums have been voted for its maintenance by the Irish and Imperial Parliaments. Although so near Dublin, the immediate surroundings of the garden are quite rural, the extension of the city during the last half century having been to the south and opposite direction from that of Glasnevin. The ground occupied comprises thirty-one acres, and is naturally beautifully undulated; the central portion being sixty-five feet above sea level, though only one and a half mile distant from it. This elevation commands an extensive view of the Dublin and Wicklow mountains on the south, and of the agrarian county on the north, east, and west. It is further beautified by the river Tolka forming the boundary on the north, which enables a stream of water to be conveyed through the aquarium, which, consequently, only gets stagnant during dry seasons, when the river is very low. It was formerly the domain of the poet Tickel, Addison's friend, by whom many of the trees still standing were planted. The locality has consequently a sort of classical interest attached to it. The collections of plants in the several departments of stove, greenhouse, herbaceous, alpine, &c., are all extensive; the more recently introduced kinds being well kept up according as they appear in commerce.

The conservatories are also on an extensive scale, two of the ranges being upwards of three hundred lineal feet each, varying in height from fifteen to sixty feet at their centres and wings, besides other ranges of detached pits and small houses. As in other metropolitan botanic gardens, plants which are useful in medicine and the arts receive special attention here, but

PLAN OF THE ROYAL BOTANIC GARDENS AT GLASNEVIN, DUBLIN.

the more showy kinds are not held altogether subordinate to the former, convenience being afforded for both to be well attended to. The principal conservatories are therefore kept well furnished with flowering plants at all periods of the season. Palms, ferns, pitcher plants, and cacti are specialties of which there are good collections, and also a fair collection of orchids. The herbaceous department is one of the most extensive and best arranged to be met with in any botanic garden in Europe at the present time.

This establishment is open to the public daily, from twelve to four o'clock in winter, and from one to five in summer. Being at a considerable distance from the most fashionable side of Dublin, those who have time to visit botanic gardens on week days are small in number compared with the Sunday visitors, who resort in large numbers to the garden. The director, Dr. Moore, in his report for 1871, states, that 54,068 persons visited on week-days, and on Sundays, 169,760. He further states that no material damage was done by them. When we last had the pleasure of seeing these gardens we were much pleased to observe that the comfort of the assistants had not been neglected among the many recent improvements which have taken place. A good two-storied house has been built for them with reading-room and other conveniences.

Paris Gardens.—In the great nursery gardens of Paris we learn there is now an abundant and well-cultivated supply of plants for embellishing the promenades and public squares. The squares are again well kept, and Paris will soon be as beautiful, from a gardening point of view, as it was during the brightest days of the Empire. The same cannot be said of the tree plantations, which, although nearly completed, leave much to be desired.

GARDEN DESTROYERS.

THE WHITETHORN SAWFLY.

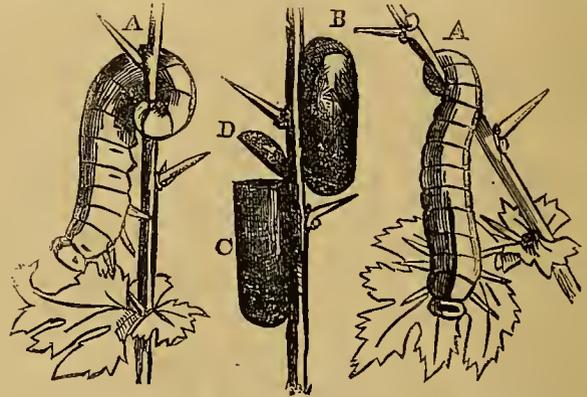

In what is called the merry month of May, the whitethorn sawfly may frequently be seen buzzing about the hedges like a great hairy bee that has lost its way; its flight is so eccentric as to seem altogether purposeless, and it is far more likely to strike you in the face, and then fall plump down in the road or pathway as though desirous of being trodden under foot, than to make any attempt to escape so dangerous an enemy as either man or boy. It is totally ignorant of fear, and has no idea whatever of self-preservation. Yet this strange and seemingly uncouth creature possesses the instinct needful for the continuation of its kind. Its apparently blundering and meaningless flight is often arrested by its legs catching in the twigs of the hawthorn; when this happens its claws serve as grappling-irons, and suddenly bring it to a standstill amongst the newly expanded or just expanding leaves. A "happy thought" now seems to strike the creature, for no sooner is its blundering career interrupted by a hawthorn twig, then in a state of tender youth and succulence, than it commences the apparently agreeable task of sawing a little slit in the rind, and depositing therein a single semi-transparent egg; and, this feat being performed, it proceeds to find another twig, apparently in the same blundering manner, and then another, until it disposes of all its eggs, laying one, and generally only one, on each twig. I am not aware that any precise observations have been made as to the number of days passed in the egg state; my first acquaintance with the caterpillar is when about half-grown; it is then of a pale sickly green colour, but covered with small white flakes, which come off on the hand when touched; this clothing is very singular, and its object, whether for adornment, warmth, or protection, has not been ascertained; the head is white, excepting only the crown and a spot on each cheek, which are black; in the cheek-spot is situated the eye; the body is wrinkled transversely as though divided into a great number of little rings; down the very middle of the back is a darker stripe; the legs and claspers are pale green.

Unlike the majority of sawfly caterpillars, those of the whitethorn seem to feed only by night. On a hawthorn hedge in my neighbourhood, I saw such a multitude of these caterpillars one evening, that it looked as though loaded with white fruit: some were suspended by their tails, and sprawling their legs about in the air; others were feeding vigorously; others again were rolled in a compact ring round a twig of the hawthorn; one and all seemed fully engaged. The following day I went to the same spot in the forenoon, expecting to witness a morning performance; in this I

was doomed to disappointment—not a caterpillar was to be seen, nor could I find one by searching the twigs and leaves with the utmost care. At last I made out to my entire satisfaction that they descended towards the roots every morning, but reascended the stems after sunset and made a night of it. At night I collected a number, with a view to watching their movements and making a more precise description.

On each side of the body is a row of apertures, through which the creature discharges a watery fluid on being annoyed. On these occasions it evinces a strong disposition to throw itself on the ground, always first arranging its body in the ring form; but the attempt to drop is often frustrated by a leaf or twig being included in the ring, and the twig thus decorated with its living burthen is a very curious object. Just below each of the above-mentioned apertures is an oblong spiracle. The head, when the caterpillar is full-grown, is yellow, with a raw-sienna-coloured blotch on the crown.

In July or August the caterpillar ceases his peregrinations up and down the stem, and, having found a place exactly to his mind, constructs of glue a very hard oblong cocoon; this is most firmly attached to a twig, and is of a very dark brown colour—in fact, it so closely resembles a lump of gutta-percha in colour, substance, and texture that imitation cocoons might be made of that substance which would deceive the most experienced entomologist. Having carefully ensconced himself in his new dwelling, the caterpillar rests from his labours, and takes life very easily for the next eight months. All the change that I can observe is a gradual shrinking—a growing smaller by degrees, and beautifully less. In October it is evidently smaller than in August; smaller still, and more shrivelled, in December; and again smaller still in March. Its colour also undergoes some little change; it becomes yellowish, and has a very indistinct

The Hawthorn Sawfly. A A, caterpillars of the natural size; B, a cocoon; C, the same after the perfect insect has escaped by cutting off the top, D.

transparent appearance. The head is yellow, except the crown, which is brown; the legs are huddled up close to the mouth, and the claspers look as though drawn into the body; little is to be seen of them, but there are small cavities in the places they formerly occupied. These changes indicate the greater change—that to a chrysalis—which invariably takes place in March or April, after the creature has spent about forty weeks in the caterpillar state, during thirty-four or thirty-five of which it has been a total abstainer, eating and drinking nothing, and gradually diminishing in bulk.

The chrysalis is of a dingy green colour, but shining, and having brown cases to the wings and body. Every limb, every part of the body, is plainly distinguishable, although it is enveloped in a separate skin or covering; the antennae, eyes, mouth, legs, wings, even the saw of the female, are almost as distinct as in the perfect insect; but all is still as death—there does not appear to be the slightest power of motion. The chrysalis state does not last long—rarely more than twenty or twenty-five days, sometimes not so much as either; and then the colour gradually deepens, until it assumes almost the black-brown tint of the perfect insect which is now about to appear. The final change is a rapid one, and the mode in which the prisoner obtains his release is very singular. The fly is furnished with enormous sickle-shaped, sharp-pointed jaws; and, instead of applying any solvent to the interior walls of the cocoon, as some of the moths certainly do, it uses these formidable weapons to cut off the upper portion of the cocoon, just a little shallow cup-shaped lid, which hangs for a few moments, and then falls and is lost. The cutting of this circular lid is a work of the greatest nicety, and the precision with which it is executed is truly wonderful. The point of one mandible is first seen puncturing the cocoon and protruding beyond it; it is then withdrawn by a semicircular movement, its

sharp edge meeting that of the opposing mandible, which is seldom visible on the outside; the two mandibles continue to open and close with a scissors-like certainty, the outer one being frequently visible, the inner one rarely so, until the circle is completed, and the incision returns, as it were, into itself. The released sawfly then slowly emerges, the antennæ being first projected, and the legs immediately afterwards. The creature comes out with great deliberation, and, crawling up the hawthorn twig, allows its wings to hang down and harden; it should, however, be observed that the wings of this insect are never observed, even on their first emergence, in that soft and crumpled state so noticeable in lepidoptera. The stigmoidal spot on the costal margin of the forewings is, in reality, an articulation or hinge, and at this point the wings are folded so long as the insect remains in the cocoon.

These cocoons, both before and after the emergence of the perfect insect, are very conspicuous objects in our hawthorn hedges, and schoolboys are familiar with their use as whistles; the lid is separated from the cup exactly in the place which leaves the whistle of the most perfect form. The scientific name of the whitethorn sawfly is *Tenthredo cratagi*.—*Edward Newman, in "Field."*

THE YELLOW ROSE-LEAF SAW-FLY.

(*ATHALIA ROSÆ.*)

THE insect represented in the accompanying woodcut is a saw-fly, which in the larval state feeds on the leaves of the rose tree, and at times, besides disfiguring it, injures it by abstracting the nourishment which it would otherwise have derived from the healthy action of the leaves. The perfect insect is a yellow saw-fly, with the whole back of the body (the thorax) and of the head of a deep black colour. The larva has twenty-two feet, is dark green upon the back, lighter on the sides and breast, and has a reddish yellow head.

It appears in May, and is most numerous in June and July; and a second brood appears at the end of September and October. The rosarian will recognise the presence of this insect by finding his rose leaves assuming the aspect of thin ghosts or skeletons of leaves,

The Yellow Rose-leaf Saw-fly.

with the upper surface eaten away, and nothing but the under skin left, transparent as gauze; whenever he finds this he may be pretty sure that the *Athalia rosæ* has been at work.

The female lays her eggs on the mid-rib of the rose leaf, and the larvæ browse on its upper skin and the chlorophyll, without penetrating the skin of the underside. When it is matured, it allows itself to drop from the leaf, makes its way a little into the ground, and there spins a cocoon, out of which the saw-fly escapes in August. The winter generation remains in the shape of shrivelled up larvæ until May in the following year before it is developed. The larvæ are said also to feed on the leaves of *Sedum album*. Hand-picking is the means adopted for getting rid of this insect. A. M.

WATERCRESS GROWING IN FRANCE.

THE systematic cultivation of watercress was unknown in France until 1811, when M. Cardon, an officer of the Grande Armée, established at St. Léonard, near Senlis, cresseries similar to those he had seen at Erfurt, forming a bright green oasis amidst the snows of the winter of 1808-9. In 1835 a report of M. Héricart de Flury called attention to the success which had crowned M. Cardon's efforts, and the Central Society of Horticulture gave encouragement to the further cultivation of this plant by awarding him for his fine cressery of forty beds (covering fifteen acres) their grand medal. From that time watercress-growing made rapid strides, and cresseries were shortly to be seen in all the valleys in the neighbourhood of Paris. In some instances, it is true, the results obtained were unsatisfactory, and much time and trouble were wasted in the attempt to produce cress in situations in which, owing to the insufficient water supply, it could not possibly thrive. In spite, however, of ill-success in certain cases, the cultivation of watercress had, in 1855, assumed such proportions that the number of beds then supplying Paris with their produce had increased to 710; and at the present time there exist, we are told, no fewer than 950, nearly half of which have been laid down, and are worked by M. Billet, at Duvy (Oise), and at Gonesse (Seine et Oise).

The cressery of Duvy, formerly a swampy meadow is situated in the lowest portion of the valley crossed by the road from Paris to Crépy, and advantage has been taken of the river St. Marie and a canal, as well as of several fine springs in the neighbourhood, to secure for the numerous beds into which the "culture" is divided a constant flow of fresh water. The springs alone are said to furnish no less than 12,000 to 13,000 gallons a minute. M. Billet, however, does not rely entirely upon water as a fertilizing agent, but turns to account as manure the droppings of a herd of thirty cows. He finds that in spite of a certain portion of this application being washed away by the current, a sufficient quantity remains to have a marked influence on the crop. The cress, instead of being thin and stalky, develops a luxuriant growth of close-set leaves, and its flavour becomes at the same time less bitter and more piquant. To distribute the manure the workman makes use of a large wooden rake without teeth (so-called *schaële*), forcing it in between the leaves of the green herbage, and by the same movement pressing down the stems which the labourer engaged in the preceding operation, that of cutting, had left erect. To facilitate the cutting, a plank is placed across each bed, and the workman, kneeling on the same, draws a bunch of cress towards him with one hand, and cuts it with the other. Great care is taken not to "crop" the luxuriant head to be operated upon, but simply to "thin" it; and so well is this point attended to, that an unpractised eye fails to distinguish cut from uncut beds.

As fast as the cress is cut and tied—and a skilful labourer will do this work at the rate of 100 bunches an hour—it is thrown into water on the shady side of the bed, and then removed to a reservoir under the kiosk. It is afterwards packed and forwarded to Paris in baskets which hold 100 bunches, and are made in the shape of a cylinder, so as to allow of a free passage of air down the centre. The operations of cutting and manuring succeed that of rolling, and the roller in use is one which, on account of its peculiar construction, M. Billet considers specially adapted for the purpose. When it is desired to lay down fresh beds or renew old ones, the necessary supply of plants is procured by thinning those spots in the cressery where an over-luxuriant growth is observable; and as to weeds, which no amount of vigilance can prevent from occasionally making their appearance, all that is needful to succeed in eradicating them is the exercise of a little patience and attention.

The second cressery of which he is the proprietor—that of Gonesse (Oise et Seine)—presents, as regards character of the soil on which it is established, a remarkable contrast to the one we have just described; for whereas that at Duvy is situated in what was formerly a swampy peat bog, the beds at Gonesse are laid on a firm sandy clay of considerable agricultural value. Although, however, the soil in one of these two localities is greatly inferior to that of the other, the produce per acre is about the same, and it is therefore evident that the successful cultivation of watercress depends far more upon the quality, quantity, and method of distribution of the irrigating water—in the above cases almost identical—than upon the character of the land. No herd is kept at Gonesse, but manure is purchased from cowkeepers in the suburbs of Paris, and applied in the same manner as at Duvy. As to the result of the two undertakings, we are informed that each of them supplies Paris with about 200,000 dozen bunches of watercress per annum—which is equal to an average of 1,000 dozen per bed—and that M. Billet, who is constantly adding to the extent of his watery domain, can command a higher price for his produce by some centimes than is obtainable by any of his competitors in the market.

MARKET GARDENING.

BY H. EVERSHED.

(Continued from Vol. I, p. 632.)

THE courtesy of Messrs. T. & J. Mathews, of East Ham, Essex, and Wandsworth, Surrey, enables me to describe the management of an extensive garden-farm, lying within seven miles of the General Post Office, and occupying a site remarkable for historical memorials, and still more so for certain modern works. The Danes crossed it when they rowed up the Roding to Ilford; the Romans had a burial-place on it; and a few years ago the main sewer of North London was carried through it. These and other intrusions have cut up the farm to some extent, and perhaps it may some day be overwhelmed by works of trade and commerce. Acreage: 620 acres in the parishes of East Ham, Barking, and Little Ilford. There are about 420 acres of gravel loam and 200 acres of alluvial land drained by "sewers," that is, open ditches which are under management and capable of being drained into the Thames at low tide. Situated in the valley of the Thames, within one mile of the river and immediately opposite Woolwich, this farm, like the rest of the garden district, lies on a flat. The nearest rising ground is at Epping, to the north, and Shooter's Hill across the river. Technically, however, the farm is divided into the light land called "upland," which is from 10 to 20 feet above the water level, and rests on a bed of gravel, and the marsh land in Plaistow, and East Ham Levels, which is below the water-level at high tide. Eighteen inches of dry mud forms here a desirable *locus statio* for many kinds of vegetables, though not for corn. Magnificent crops of common and red cabbage, parsnips, and long red mangold, are growing on a surface that is only just out of the water at any period of the year. Water oozes into the furrows, where deep ones are drawn here and there; it fills the intersecting ditches and the main sewers. Water, almost stagnant, and covered at this warm season with a thick green scum of vegetation, bounds and protects the fields; and during the whole period of the growth of the crops it fills the subsoil at less than 24 inches from the surface. But the upper layer of this mud-bed is almost always dry, crumbling after a few hours of sun or wind into a soft, black earth, which may be lifted in handfuls that leave no stain of dirt.

The marsh land was converted from pasture by ploughing 15 years ago, and, after a succession of such crops as I have named, with onions and potatoes, it is still so strong as to require but little manure, which in the case of parsnips might induce causer at the crown, and in the case of onions might possibly bring on an affection called "booting," a term expressing the situation of young onions when they sink away, or, so to speak, "sink down into their boots." Onions are liable to be overcome in this way when sown too frequently in the same field, or on a cold, stiff, unsuitable soil, or in an ungenial situation. The more artificial the treatment the nearer the disease, and the cultivation of onions is certainly artificial when they receive 50 tons of manure per acre; young onions, however, in the condition described, seem to suffer from want of vitality rather than from any specific disease. The size of the fields on the farm, generally large, varies from 60 acres to 4 acres. The elm is the native tree. The situation of the farm is anything but rural; and its surroundings, especially on the river side, are incongruous with agricultural operations, if not forbidding in their aspect. There are in the immediate neighbourhood enormous gasworks, jute factories, docks, an arsenal, a forest of ships' masts, and acres covered with tall chimneys, and, besides the noise of great industries and a large population all around, there is the roar of constant artillery practice at Plumstead Marsh. The average of rent, tithe rent-charge, rates, and taxes is, together, £5. 15s. an acre, rates being about 18s. to 21s. an acre in the several parishes, and tithes 14s. an acre. The number of farm horses averages about 50, varying from 47 to 52. The yearly expenditure in manual labour is nearly £5,000, or about £9 an acre.

The quantity of manure purchased yearly is about 10,000 tons, besides bones to the value of £300. The live stock at the present consists of 25 bullocks, and 220 sheep to eat the aftermath. A large portion of the manure is brought from London by the waggons returning after carrying goods to market. The farm is divided into 540 acres of arable, and 80 acres of grass land. About 160 acres produce two marketable crops yearly, or, if it can be so expressed, 700 acres of crops are grown in each year on the 540 acres. The principal crops, and the customary breadths of each, are the following:—potatoes, 200; onions, carrots, and parsnips, 130; cabbages, 90; corn, principally wheat, and turnip, cabbage, and other seeds, 50; rhubarb, 20; mangold, 20; a variety of small crops and seed-beds, 30. The second crops are collards, following potatoes, cabbages, or onions; potatoes following spring cabbages; mangold transplanted after cabbages up to about 10th July; and savoys and cabbages after any other crop removed in spring.

The rules observed in cropping are to apply heavy dressings to the

gross-feeding crops; to place some others, such as onions, at wide intervals in the rotation; to select the best land for crops like cabbages and savoys, which require strong land; to keep the breadth of potatoes within 200 acres; to use corn, which is not a paying crop, as a rest or change for the land, and mangold as a cleansing crop, *i.e.*, one which induces a healthy growth in the next crop. No regular rotation is adhered to, but the following examples may be taken as an approximation of the system of cropping:—1, potatoes and greens; 2, parsnips or carrots; 3, mangold; 4, onions and cabbages. Or, 1, cabbage and savoys; 2, parsnips or carrots; 3, onions; 4, potatoes. In order to give the reader a general idea of the distribution of the £9. per acre per annum expended on labour, I shall notice the main items connected with each crop.

(1.) POTATOES AND GREENS.—The land is left unploughed till March; it is, however, cultivated deeply in spring for this crop and for most others. As the next year's crop ought not to be manured, the potatoes get an unusually heavy dressing, such as 30 tons of short manure per acre, ploughed in with three horses and a 10-inch furrow in March. The sets are planted in every other furrow, at 18 inches by 15 inches in the row. They are hoed and moulded in the usual way, and marketed in June, July, and August. The potato-gang were lifting a large crop of early potatoes, exceeding 4 tons per acre, on July 7th, at 6s. 8d. per ton, weighed in the field, and the haulm raked neatly into wide rows. In a few days the price would be reduced, and the cost of lifting a heavy crop of 10 tons of late potatoes would be about 4s. per ton. The ground is harrowed at the time of lifting the potatoes, and is immediately ploughed deeply, with three horses, for the collards, which are dunged heavily if they are to be followed by carrots, and are not manured if parsnips are to be the next crop. The plants are set one foot apart, at a cost of 20s. per acre for labour, and 40s. an acre for the plants, supposing one acre of seed-bed to plant 14 acres of collards. This crop is hoed several times. Bunching for market costs 4s. 6d. per 20 dozen bunches. The collards having been removed during the winter, the land is cultivated deeply early in spring and ploughed 14 inches deep with four horses for

(2.) CARROTS OR PARSNIPS.—As the cultivation of the latter is described elsewhere and that of the former does not require minute description, it will be sufficient to add that the Early Horn or James's carrot for bunching is sowed broadcast immediately after the plough. The hoeing and cleaning of this crop costs Messrs. Mathews £1. an acre. Taking up and bunching, which was in full progress last season in the third week in June, costs 8s. per 20 dozen bunches, which is thus divided: the men taking up the roots, 2s. 6d.; the women washing them, 1s. 8d.; men bunching, 3s. 4d.; cost of rods, 6d.

(3.) ONIONS.—The land having been heavily manured for the previous crop, is ploughed deeply with three horses, sown with 5 cwt. per acre of bone-dust mixed with guano, and scarified: 10 or 14 lbs. of seed per acre is sown broadcast at the end of February, or early in March. The cost of hoeing and cleaning the crop is £5 per acre, and bunching a great crop costs 40s.

The spring crop of cabbages, sent to market in April, May, and June, is sown in the last week in July or first week in August, and planted at the end of September or early in October. The summer crop of cabbages is sown in succession, commencing in open weather in spring. The seed must not be sown too early, as the young plants become blind when frost-bitten.

(To be continued.)

Weeds on Walks.—I have a weed-killer which perfectly answers that purpose, at least as far as walks are concerned. It has various names, but that by which it is best known is muriatic acid. It can be supplied from the makers at about five shillings or six shillings per cwt. It completely destroys all vegetable life (insect and animal as well) mixed at the rate of half a pint to the gallon of water. One application of this will keep walks free from weeds, moss, or worm casts for two years. As regards its application, it is only needful to wet the walk with it; in two seconds the weeds and all insects will be killed, and in a few hours after they can be swept off; or, if left, it does not matter much, for in a day or so they become shrivelled up, leaving the walks greatly improved in appearance, owing to the nice gloss it leaves on them. On broad walks, I put it on with a large watering-pot and ordinary sized rose. It is not necessary on hill walks to put it on so heavily that it will run; for of course wherever it touches grass edgings or box it at once kills them. Even in the case of narrow walks, however, if carefully used and run through a smaller rose no harm need be apprehended. As respects conditions, dry weather is better than wet for applying it, as it soaks in before it can be washed to the sides. Properly applied, I can only repeat that it is the finest remedy for weeds on walks I have ever met with.—J. G. TEMPLE.

THE GARDENS OF ENGLAND.

ALTON TOWERS.

THE chief features of this beautiful place are the house, "The Enchanted Valley," and the drive of rare length and beauty that leads to them. The last introduces one to scenery more akin to that found in the highlands of Scotland than anywhere else. It pierces, winds, and insinuates in bends of more than Grecian elegance through miles of hanging woods, approaching sometimes to the boldness and precipitancy of mountain scenery. The carriage-drive is mostly cut out of the side of a hill, and commands every feature of interest along the route. The wood is rich and varied, and abounds in out-cropping masses of rocks, natural ferneries of rare breadth and magnificence, that make our artificial imitations little and poor indeed. Almost every feature of woodland scenery is unfolded as one drives along the carriage-road. Of course, the predominating character is that of a hanging wood of almost interminable extent. But now it widens out or closes in; at times it is comparatively smooth, and again rocks and under-shrubs and ferns jostle each other for the mastery. Anon, we sweep round a curve, and come in sight of a broad lake. Through such scenery, affording the most charming bird's-eye views of the opposite valley, we drive on and on, until at last "The Towers" themselves are seen and reached. It speaks much for the dignity of the mansion to be able to add that it bears the strain of the noble interlude—the grand approach—well. It is a worthy terminus to such a drive. This is a point that is often badly managed—the correlation, if we may so put it, between the length, width, and general importance of the carriage-drive and the house.

Alton Towers, as is well known, is a magnificent example of Gothic architecture, and bears the impress of the master-mind of Pugin. More need not be said, but that the chapel, mansion, and all its surroundings constitute a grand whole of rare purity, massiveness, and grandeur. A fine conservatory is attached to the house; and there are flowers and gardens in the different courts and on the terraced platform. Most of the plant houses are also placed near the house, and contain an extensive collection of stove and greenhouse plants and orchids. But the style of gardening around the house, immediately we leave the courts, is hardly in keeping with its grandeur, and is capable of great improvement. The site of the strawberry grounds, for instance, and the entire space between these and the mansion, should be converted into a geometrical or Gothic flower garden to harmonise with "The Towers." Let us now hasten from the glories of Gothic architecture to the lighter and more fascinating charms of "The Enchanted Valley."

This is a splendid medley of waving wood and rolling surface—of falling waters of dark cedars and green glades—of archi-

ture and artistic gardening—of gilded temples, Swiss cottages, panelled walls decorated at the basement with floral mosaics, light and shadow—a rich commingling of nature and art, with the former everywhere predominating.

To appreciate the scene as it is, it is needful to look back, and grasp the idea of what it was meant to be. The past history of this valley, as of most things, pours a flood of light on its present condition. Time was when art, high and dry, reigned supreme here. Everything was faultily faultless, splendidly regular, evenly trim. The rod, the line, the shears, the knife, bore rule for years after the valley was planted and furnished, and the effect, we are told, was at that time admirable.

(To be continued.)

D.

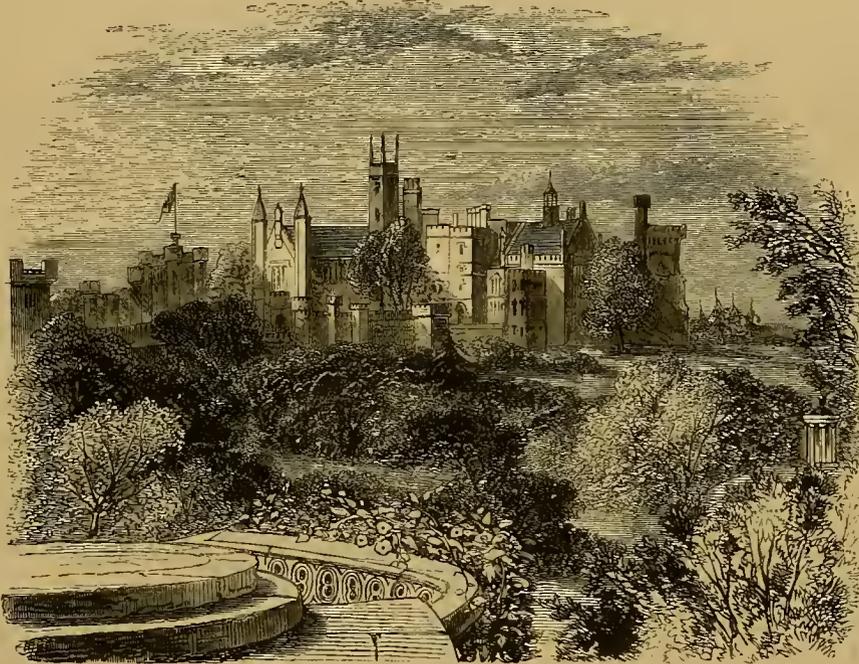

THE RELATIVE INFLUENCE OF PARENTAGE IN FLOWERING PLANTS.

READ BY DR. DENNY, AT THE BIRMINGHAM CONGRESS.

FROM early youth I have taken much interest in artificial fertilization, but kept no registered account of my crosses, or their results, until the controversy arose respecting the tri-colored Pelargoniums, as to whether their leaf markings could be re-produced by fertilization and seed, or whether they were sports only, and owing to a diseased condition of the plant. To ascertain for my own satisfaction the correct theory upon these points, as well as with the object of obtaining, if possible, some information regarding the relative powers the respective parents exert over their progeny, I commenced a series of experiments upon the scarlet section of the Pelargonium, employing varieties of the most opposite and varied character, and crossing them in every conceivable way. I conducted these experiments too with the utmost possible care and minuteness of detail, both as regards the methods I adopted for preventing self or insect

fertilization, for insuring the fertilization being effected by the desired pollen only, and as regards the keeping an exact register of every cross, as well as record of their results. By this means I soon arrived at a satisfactory conclusion as regards the points at issue respecting the transmission of variegation of the foliage by fertilization, from the fact of its being manifested, to a greater or less degree, in as large a proportion as from fifty to sixty per cent. of the offspring, where the green zonal had been fertilized by the pollen of the variegated; I also obtained some valuable information indicative of the powers the respective parents exert upon various other points in connection with the transmission and modification of the foliage and habit of the plant, as well as of the colour and form of the flower.

From the information thus derived, I am of opinion that, by careful and persistent fertilization, under the guidance of the observation of results, it is possible to produce almost any modification in the character and habit of our plants, and variety of colour and form in our flowers, we may desire; for I am satisfied that by these means we possess a much greater power of moulding our flowers in accordance with preconceived design than is generally supposed; and, moreover, I think it possible that ultimately some insight might be obtained into the working of the laws that govern procreation in the vegetable kingdom, and that produce variation in our fruits and flowers. The result of my experience, derived from these experiments, as regards the relative influence of the parents, certainly tends in the reverse direction to my previous ideas, which were derived from books, from which I gleaned that the form of the flower, and constitution and habit of the plant, were inherited from its mother;

Alton Towers.

whilst the colour of the flower only was supposed to be conveyed by the father. The recorded results of my crossings indicate an immense preponderance of influence over the progeny on the part of the father in all respects—in colour and in form, in the quality, in size and substance of the flower, as well as in the production of variegation of the foliage, and in the habit and constitution of the plant also, provided the plants employed are of equal strength.

I wish to be distinct upon this point of relative strength of the parents, because it seems to me that upon the equality, or the preponderance, of strength on either side, very much hinges, as regards the results we obtain from our crossings; for power of constitution exerts most unmistakable influence, and where it preponderates on the part of the seed parent, it will modify the otherwise prepotent influence of the pollen parent; this modifying influence manifests itself most as regards the habit and foliage of the plant, and next as regards the form and substance of the flower; and, lastly, as regards the production of a blend in the colour of the flower. To instance what I mean (I am alluding to the *Pelargonium*), if the pollen of a flower of brilliant and decided colour, but of bad form and substance, belonging to a plant of weakly constitution, be applied to the stigma of a finely formed, thick-petalled flower, of a plant possessing a vigorous constitution, some few of the progeny will be influenced towards improvement in the form and substance of the flowers and habit of the plant, with perhaps some blend in the colour; showing that the preponderance of vigour in the seed parent had exerted a certain amount of influence; but even under these circumstances much the greater proportion of the progeny would resemble the father in all respects, or show reversion, either towards former progenitors, or towards an original type.

I will quote a case or two in point from my note-book. During the summer of 1869 I raised about one hundred and forty seedlings from crossings between Lord Derby and Leonidas; in about half of these Lord Derby was the pollen and Leonidas the seed parent, and half resulted from crosses effected the reverse way. The flower of Lord Derby possessed fine qualities, both as regards form of petal and smoothness of texture, but was wanting in depth and brilliancy of colour, and in substance also, and the plant was deficient in vigour of constitution as compared with Leonidas. The flower of Leonidas was much inferior as regards form and quality, but of greater substance and brilliancy of colour, as well as larger, than Lord Derby, and the plant possessed a vigorous constitution.

These seedlings flowered during the spring and summer of 1870. Of that portion in which Lord Derby was used as pollen and Leonidas as seed parent (the seed parent, observe, being the most vigorous), about one-third resembled in all respects their father; a few produced flowers very considerably in advance of Lord Derby, in size, in substance, and in colour of the flower, and with a superior constitution and habit of plant, showing the mother's influence in combination with that of the father. (I would instance Sir Charles Napier as an example and which resulted from this cross.) Of the remaining two-thirds, a few very nearly resembled in flower Leonidas, except being paler in colour, and having a somewhat increased breadth of petal, resulting from the father's influence (for instance Iago), but a large proportion were inferior, showing reversion towards an ancestral type. Of that portion in which Leonidas was used as pollen and Lord Derby as seed parent, nearly half resembled in all respects their father, and the rest were much inferior; not one showed that any appreciable amount of influence had been exerted by the mother towards improvement. It will be observed that in this cross the pollen parent possessed both the inferior flower, and the most powerful constitution also. As regards the habit of these seedlings, they were all more robust than their mother. The same season I raised about sixty seedlings from a cross between Celestial and Lord Derby. Celestial, which was used as pollen parent, possessed a brilliant magenta-coloured flower, but of very bad form and substance, and possessed a weakly constitution; from this batch of seedlings a few produced flowers of a colour very similar to their father (but somewhat less brilliant), and with a great improvement as regards the form, quality, size, and substance of the flower, accompanied too with a fair habit and constitution of plant, showing a marked influence on the part of the mother, which in this cross, was decidedly the stronger of the two parents. (Lanthe resulted from this cross.) The remainder of this batch were mostly of very bad form and quality of flower, and weakly constitutions, but there were some very brilliant and novel colours, interesting examples of colour blending; amongst them were carmine, rose crimson, pinks, and vivid scarlets; some in all respects resembled Celestial.

My large seedling nosegay Wellington was the result of a cross between Le Grand nosegay and Leonidas; Le Grand being used as pollen parent. Here the plants were about equally vigorous. Wellington resembles in the character of its flower its father, but has an increased breadth of petal derived from its mother; the colour of the flower is nearly that of the father's also, but it is somewhat a blend, the purple hue of Le Grand and the deep scarlet of Leonidas, having produced a very dark crimson scarlet, almost maroon. The foliage, too, of Wellington is most distinctly of the nosegay type; the habit being still more vigorous than that of either parent.

In breeding for "variegates," and using the variegates (which as a rule are wanting in vigour) as pollen parents and the robust green zonals as seed parents, about half the number of their progeny showed variegation and possessed weakly constitutions, the remainder being green zonals; upon the order of procedure being reversed, by which the pollen parent became the parent of very much the greater vigour, the mother's influence was almost nil. I believe that in plants with long-established properties it is owing to the existence of a difference in the vigour of the parents that the produc-

tion of novelties and varieties in our flowers (and probably in our fruit too) mainly depends, and that were it not for a preponderance of power on the mother's side, the progeny would almost invariably resemble the father; and hence the immutability of our flowers and vegetables, which are annually re-produced from seed, the result of self-fertilization. But I consider that another source of the production of novelties and variation exists in the tendency in all flowers (and fruits) that have been artificially bred up to a state far in advance of their original condition, to revert towards former progenitors (especially under the influence of self-fertilization), by which means new combinations of ancestral properties are formed, and hence new varieties.

Even under artificial fertilization I find in the *Pelargonium* this tendency to reversion to exert very considerable modifying influences; especially have I observed it as regards the colour of the flower; for instance, the magenta shades that have been produced upon the scarlet *Pelargonium*, have resulted from the crossing of pinks upon scarlets; and very many of my seedlings, the offspring resulting from the crossing of two magenta-coloured flowers, have produced pink ones as well as scarlets, showing reversion to both the colours of their immediate ancestors. It is a point worthy of observation, whether the colour of a flower, or a change in the character of a plant that has been recently obtained, is conveyed to the offspring in the same proportion as to numbers, and with the same certainty as those of long standing? I think not. I must also mention a remarkable instance of reversion as regards foliage that has occurred in two of a number of seedlings raised this spring from Violet Hill nosegay as seed parent, crossed by Lanthe, with the object of obtaining variety in the flower; two of this batch of seedlings have come variegates; now Violet Hill was bred for variegation, and was planted out at Messrs. Henderson's establishment at St. John's Wood in the spring of 1864, with a view to its breaking into variegation, but which it did not do, but was selected and subsequently sent out for its flower, and on account of its dwarf habit of growth.

A close analogy seems to me to exist between the vegetable and animal kingdoms as regards the ill effects produced by breeding in and in, and the good resulting from crossing opposites; for I find it to be necessary for the maintenance of improvement in the flower and the constitution of my seedlings, to introduce fresh varieties to breed from annually; and I find that crossing two flowers of the finest qualities does not produce such satisfactory results as where one of much inferior quality is employed; of course, it will be inferred from my previous observations that I use the superior quality flower as pollen parent.

As regards the condition of the atmosphere that favours the effecting of difficult crosses, my experience indicates that bright, clear weather, and the hours of sunshine are conducive to fecundation.

I have alluded to the antipathies and affinities we find to exist without any explicable cause; for instance, I have found it impossible to fertilise three or four varieties of the scarlet *Pelargonium* (viz., the Duke of Cornwall, Dr. Muret, Beauty de Surrennes, and all that section of the doubles which sprang from Beauty de Surrennes), which to all appearance are mere varieties of the zonal section, save with one another; and showing the existence of affinity between what are supposed to be distinct species. I have fertilised without much difficulty a variety (*Peltatum elegans*) of the ivy-leaved section by the pollen of the zonal.

I have also alluded to the possible difference in the respective influence of the parents in true hybridization. Upon this point I have not sufficient evidence to form a fair opinion; but certainly in the seedlings I have raised between the ivy-leaved and zonal sections, their foliage (with the exception of some distinctive evidence of their being hybrids) resembles almost entirely that of their mother, which, you will observe, is the reverse of my experience of the results produced between varieties.

Much has been written and said upon the difference in the quality and powers of the pollen of the short stamens; and if the supposed difference really does exist, it is a matter of considerable practical importance, and one worthy of further scientific investigation; but my experiments have hitherto failed to satisfy me of their possessing any difference.

In an admirable article on hybridization by Mr. Isaac Anderson-Henry (see Vol. I., p. 480), he says, "That owing to the granules of the short stamens being smaller than those of the long ones, they can the more easily descend the tubules leading from the stigma to the ovaries, and consequently facilitate the crossing of a large-flowered variety or species upon a smaller one." I have not been able to detect this difference in size, although I have many times placed the granules of the long and short stamens side by side under a powerful microscope; nor, I believe, is it the opinion of physiologists of the present day, that they do descend these tubules at all; in fact, it has been shown that they send down filaments through them to the ovules. The arrangement of the anthers upon filaments of different lengths looks to me like a provision to insure all parts of the body and legs of insects coming into contact with the pollen as they pass down the flower to obtain the nectar, thereby rendering the fertilization of the next flower they visit the more certain.

Lastly, I would remark, that to enable reliable conclusions to be drawn upon any of these points, we require an accumulation of data derived from the careful observation of very many unbiased workers, whose results have been obtained from experiments conducted with scientific precision, upon all our flowers and fruits. Such an accumulation of recorded facts (if they could be obtained), would prove a source of the greatest interest to the philosopher, by their tendency to throw some light upon the working of nature's laws, and could not but afford most valuable information for the guidance of the practical horticulturist; and moreover by freeing horticulture from all empiricism would place it in its true and legitimate position among the modern sciences.

THE ARBORETUM.

THE FUNERAL CYPRESS.

(CUPRESSUS FUNEBRIS.)

THERE are three Asiatic Cypresses, namely, *funnebris*, *corneyana*, and *torulosa*, all of which have a pendulous habit when old, and bear considerable resemblance to each other. In the countries where they grow they are known by the name of weeping cypress. The Funeral Cypress is a native of the north of China, and, when full-grown, forms a tree sixty feet high, with forked branches and a spreading head, thickly furnished with a slender, pendulous spray; while young it is rather compact, and somewhat erect, but in proportion as it increases in size and age, it becomes graceful and drooping. The leaves on young plants are distant, linear, and glaucous, and very different from the old trees, which are oval, and closely imbricated in four rows. This cypress is quite hardy; it was first introduced into this country in 1849, by Mr. Fortune, to whom we are indebted for so many fine plants, both from China and Japan.

Like all cypresses, it is well worthy of a place in every collection of graceful evergreen trees. As yet, few examples of it in this country are above twenty feet high, but these sufficiently prove that the older it gets the more graceful it looks. It somewhat resembles, except in colour, old trees of *Cupressus tornulosa*. With the Chinese it is a great favourite for planting about tombs in burial grounds.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE JERUSALEM SAGE
(*PHILOMIS FRUTICOSA*).

THIS forms a dense evergreen bush, from two to four feet high, with a greyish aspect. It grows naturally on mountains and other dry exposed places in Spain, Sicily, Greece, and the Levant. It was first introduced into England in 1596. It is a plant which thrives well in any common garden soil, and is easily increased either by means of layers or cuttings of the half-ripened wood. When planted on the upper part of rock-work, and fully exposed to the sun, it makes a fine display in June and July, when furnished, as it usually is at that season, with numerous whorls of yellow flowers.

Its leaves are opposite, ovate, or oblong, roundly wedge-shaped at the base, wrinkled, villose, and green above, but

clothed densely beneath with white down; they are also either entire, or more or less crenated on the edges, and measure from two to three inches in length. The branches are somewhat spreading, and densely coated with little tufts of yellowish tomentum. The flowers, which are of a dusky yellow colour, are produced at the top of the branches in solitary or twin whorls, each containing from twenty to thirty flowers, which are bilabiate or two lipped, the upper one being helmet-shaped, and the lower one spreading and trifid. The bracts, or floral envelopes, are broad, ovate or ovate-lanceolate, acute, or villose, greenish in colour, and fringed on the edges with longish hairs. The calyx is large, tubular, and villose, with five blunt teeth, which end in a spreading, awl-shaped, stiff point.

Funeral Cypress. (After Fortune.)

AMERICAN INK OR WINTER BERRY (*PRINOS GLABER*).

THIS forms a pretty ovate-shaped evergreen shrub, three or four feet high, densely clothed with dark glossy leaves; and in the autumn, when covered with its black berries, it makes a fine display. It thrives best in a mixture of sandy peat and loam; but many who have grown it find it to succeed very well with them in any good garden soil that is not stiff or heavy; it can be readily increased either by means of seeds or cuttings.

The winter berry is a native of North America, from Canada to Florida, where it grows in shady woods. It was first introduced in 1759. The leaves are an inch and a half long, alternate, leathery in texture, lanceolate, tapering much towards the footstalk, dark glossy green above, pale beneath, and smooth on both surfaces, with two or three visible serratures near the apex. The shoots when young are rather downy, but quite smooth when fully matured. The flowers are small, white, and mostly produced in threes, on solitary axillary footstalks, in July and August. The berries are jet black and ripe in September, and in consequence of their

colour, are called ink berries. "Prinos" is the Greek name for the holly.

Yew Trees.—The following particulars of a yew tree, in the churchyard at Doveridge, Derbyshire, may prove of interest to your correspondent at Long-leat. Height, 36 feet; circumference of branches, 212 feet; spread of branches from north to south, 63 feet 4 inches; from east to west, 72 feet; girth of stem at the ground, 23 feet 6 inches; girth of stem at seven feet from ground, 24 feet; smallest girth of stem, 20 feet; length of stem 7 feet. This yew tree is quite hollow all the way up, and about one-third of the stem completely gone, which will account for the girth of the stem appearing small. It is perfectly healthy, and has grown in the circumference of its branches in the last thirty years from 167 feet to 212 feet.—*T. Povey, Doveridge, in "Field."*

GARDENING FOR JULY.

THE INDOOR GARDEN.

BY T. BAINES, SOUTHGATE.

Conservatory.—Every means should now be employed to prolong the blooming of such plants as are at present in flower, as well as to encourage such as are progressing, for conservatory decoration. Owing to the greater number of these structures being usually much loftier than ordinary houses for plant growing, a much greater surface is exposed to the action of the sun; consequently the atmosphere is much drier, so much so, indeed, during the long summer days, as to make short work of the greater number of blooming plants available at this season. The borders that usually exist for climbers should be kept as moist as is consistent with the well-being of the plants growing in them; the moisture given off from them will, in some measure, counteract the dryness of the atmosphere, and on all available occasions, especially early in the mornings and in the evenings, water should be applied under the stages, where such exist, and on the tables, yet not so plentifully as to occasion the unsightly inconvenience of wet paths to walk upon. Moisture applied in this way has not only the effect of benefiting the blooming plants, but tends to keep down red-spider, which generally has a particularly genial feeding ground on conservatory climbers. The latter should have forcible applications of water from the syringe, or, still better, from the garden-engine, occasionally. Thin shading material (in all cases movable) should be used not only for the roof, but for the sides of the house next the sun, if the house is lofty. Assist by all necessary attention *Fuchsias*, *Liliums*, *Amarantus*, *Balsams*, *Pelargoniums*, *Vallotas*, *Cassia corymbosa* (yellow), *Witsenia corymbosa* (blue), two plants of easy culture, but not nearly so often met with as they deserve. *Achimenes*, *Gesnera Cooperi* and *Doncklaari*, *Tydeas*, and *Gloxinias* should be properly and carefully hardened by giving them plenty of light, and placing them near where air is admitted in the stove before their introduction to the conservatory, where they should be placed in such a position as to be as far removed from draughts as possible; by such means such plants may be made to do duty there for a considerable time; and it is necessary to employ plants of this description during the next two months, when there is a greater scarcity of blooming plants for conservatory decoration than at any other time during the year. Attend well to all autumn and winter blooming plants. The first batch of *Cinerarias* should, by the middle of the month, be ready to be placed in their blooming pots; six-inch ones will be large enough, if the plants have been well managed all through the several stages of their growth. The first batch of *Hydrangeas* should now be potted, using pure peat and sand for a portion, and loam and sand for the rest of the stock; by this means, in all probability, both the blue and pink colours will be secured.

Stoves.—Old stocks of *Poinsettias* should now be shaken out, repotted, and encouraged to make strong sturdy growth. Another useful winter blooming plant is *Begonia dipetala*. If small plants of this are now at hand, and grown on freely, they will furnish quantities of bloom in the winter. *Allamandas*, *Clerodendron splendens*, and *Dipladenias*, showing flower freely, should now be trained round their trellises, but not too closely, as that gives them too stiff an appearance, and also has a tendency to cause premature decay in the leaves, which, if allowed to overlap each other, turn yellow and decay; this has also a tendency to weaken the plants and reduce their blooming capabilities. Expose them to all the light possible, using just sufficient shading material to break the direct rays of the sun; by this means the flowers will be produced much stouter, and will stand in a cut state, if required, much longer than when treated more tenderly. Autumn-struck cuttings of hardwooded stove plants, such as *Ixoras*, *Allamandas*, *Gardenias*, &c., which have been potted during the winter, will by this time require a further shift. The aim of the cultivator ought to be to get the plants up to the required size as quickly as possible; if such things are allowed to become stunted through being pot-bound, it takes a long time afterwards to get them to move; in fact, it is better to commence with a cutting than to grow a plant on that has been allowed to get into such a condition. It would seem that the increased demand for cut flowers at the present day is illimitable; it therefore behoves gardeners to make provision to meet it. In most establishments, large or small, there will be some things held in greater esteem than others. Therefore it is impossible to name any plants in particular that would be held in general estimation. Yet during this and the next two months flowers from stove plants will be largely used for mixing with *Roses* and other outdoor productions. There is a great charm in variety; yet the old system of growing collections of plants where the object was to include the greatest number possible, both of species and varieties, is anything

but calculated to meet the requirements of the present day; it is much better to confine to a reasonable extent the number of varieties of plants grown to such as are the most attractive, last the longest, and are held in the greatest estimation. If there is one plant more than another that is more generally useful as a decorative stove or intermediate house plant, and capable of producing quantities of cut flowers for eight or ten months in the year, it is *Ixora coccinea*. Now is a good time to either strike cuttings or procure plants of it; and if kept clean from insects, and grown under the same conditions as to temperature and atmospheric moisture, summer and winter, that will suit *Cucumbers*, it will amply repay for the trouble bestowed upon it. Its flowers will stand in water for a week, and it can be cut with impunity without injuring the plants.

Fern House.—Attend well to the general stock in the way of water, especially such as have filled their pots with roots; any inattention to this matter results in the destruction of that healthy green appearance of the foliage which is the first characteristic of well-grown plants. Do not maintain a higher temperature than is necessary for healthy development; such being inimical to persistency of foliage, or to its endurance if required for cutting. Keep down insects by repeated light fumigations, in preference to performing that operation seldom and severely.

Azaleas.—These should be making active growth, which should be encouraged by syringings overhead every afternoon, shutting up early, and keeping the plants thoroughly free from their two great enemies, thrips and red-spider. Plants that require repotting if their roots are active, should be shifted at once, using nothing but good peat, and sufficient sand to keep the soil sweet. Hardwooded plants that have been potted some time, and that are growing freely, should now be no longer shaded in bright weather, but, on the contrary, should be fully exposed to the sun, throwing water liberally about under the stages amongst the pots, so as to counteract drying influences. Young stock that was potted early, and that is growing vigorously, may be benefited by a further shift.

Orchids.—Encourage these by all means to mature their growth whilst there is length of days. Use discrimination in the application of water. The thick-rooted East Indian section, and more especially such varieties as inhabit the hill regions of India, require an amount of moisture at the root that would soon be fatal to *Cattleyas*, *Lælias*, and plants of similar description that are especially impatient of too much water at the root. See well to the varieties that are most suitable for furnishing winter flowers. *Cypripedium insigne*, *Cælogyne cristata*, *Zygopetalum*, *Calanthe vestita* and *Veitchii*, these if well managed will afford a succession of flowers for four months, and the length of time they will endure in wet sand or water would surprise those who have not tried them in that way. *Odontoglossum Alexandræ* is coming into general request as one of the most elegant of flowers; in some places it is now being grown by the hundred, and may be had in flower nearly all the year round. It and its congeners require only a comparatively low temperature, with plenty of moisture in the atmosphere and at the roots, with careful shading.

Heaths.—Some growers repot such as require it about this time, when the plants have done flowering; but it is much better to defer the operation until the autumn, when the weather gets cooler. Pick off all seed-pods, if seed is not wanted, as soon as the flowers are decayed, as the production of seed greatly exhausts the energies of plants.

THE FLOWER GARDEN FOR JULY.

BY GEORGE WESTLAND, WITLEY COURT.

Now that "bedding out" has been brought to a close, in order to render the flower garden thoroughly enjoyable, the greatest possible care must be exercised to insure perfect order and neatness. Owing to the terrific hailstorms which we experienced on the 7th and 8th ultimo, and the long continuation of wet, frequent stirrings of the soil, so as to thoroughly loosen the surface, will be necessary; this will greatly expedite the growth of the plants, and save much useless labour in watering. Mulching is a safe practice; more particularly in the case of heavy soils that are liable to crack; for this purpose use some light material such as cocoa-nut fibre, spent tan, or leaf-mould. When watering is absolutely necessary let it be done thoroughly; the best time for performing the operation is in the evening, as then the plants have a chance of getting thoroughly refreshed by it. In bright sunny weather, with dry, hot nights, foliage plants will be benefited by being sprinkled overhead late in the evenings. The surface soil in flower baskets and vases should also be mulched with moss, kept in its place by means of small pegs; this will have a tendency to prevent evaporation, and will save labour in watering.

Unremitting attention must now be directed to the keeping of

climbers within proper limits. Proceed with the pegging down and training of growing plants in beds; also with the staking of herbaceous plants in mixed borders. These should not be huddled together, but should be carefully tied out so as to have perfect freedom in the way of natural development. Dahlias and Hollyhocks should have their fastenings frequently examined, and the shoots tied up, thinning out such as are superfluous. Where Calceolarias are much exposed to wind, a few short twiggy branches placed neatly among them before they are fully grown, so as to become covered by the foliage, will fortify them against very severe blasts; for the support of annuals these branches are also excellent, if used sufficiently early. The thinning of these should have attention as soon as they are fit to handle. Annuals, biennials, and perennials may still be sown, and such as were sown early transplanted into nursery beds. Remove decaying blossoms and seed-vessels from Rhododendrons and plants in general; for upon attention to this will greatly depend the vigour of the plants.

Bulbs should be taken up as soon as they are well ripened, which is easily determined by the decay of the foliage; do not, however, remove the leaves at the time of lifting, except, perhaps, such as part freely from the bulb; allow them to dry gradually off in an airy shady situation, protected from rain. Anemones and Ranunculuses be careful to take up as soon as their leaves wither, for they are apt to emit fresh roots when left in the ground. After they are ripe, be particular that the bulbs are thoroughly dry before they are stored away. A great many roots are annually destroyed by being stored away in close drawers, &c., when in a half-ripened state.

Propagate Carnations and Picotees from layers as soon as the shoots are in a sufficiently advanced state. Clip all kinds of hedges, and prune back evergreens so as to keep them within proper limits. Continue to sweep and roll lawns, keep the grass neatly mown, and the edges of the walks trim and precise.

A great majority of evergreen shrubs may now be propagated either by layering, or by means of cuttings made of half-ripened shoots. Amongst these may be mentioned Hollies, which will now root freely from half-ripe cuttings of this season's growth. Choose a situation shaded from the sun, under a north wall, or under the shade of trees, and insert the cuttings in fine sandy soil, under a frame; water freely, and slightly tilt the lights; and beyond frequent sprinklings they will give no further trouble.

Pits and Frames.—Many things may now be propagated in these. Pinks, Mule Pinks, Pansies, and all kinds of herbaceous plants, if inserted in frames or under hand-lights in a shady place, will root freely. Sow seed of Cinerarias, prick off seedlings, and propagate choice sorts from cuttings. Sow Calceolaria seed; cover it lightly with sand, and place a square of glass over the pans, on which lay some wet moss until the seeds vegetate, when they must be gradually inured to light. To Chrysanthemums afford liberal treatment; layer young shoots of them in small pits, where they are wanted in a dwarf state. Increase Pelargoniums by means of cuttings. Cut down such as are well ripened, keeping them dry until they cease bleeding, and then sprinkle them frequently overhead to assist them in breaking. Sow Primulas for late flowering, and pot on such as were raised early.

THE FRUIT GARDEN FOR JULY.

BY WILLIAM TILLERY, WELBECK.

Outdoor Fruits.—The frost in May now shows its effects in this locality by a total failure of some of our hardy fruits, such as Apples, Pears, and Plums. Small bush fruits, such as Gooseberries, Currants, and Raspberries show but partial crops; but Strawberries, although their earliest opened blossoms were injured, are a very good crop. Cherries, such as Morellos and Kentish, on the north walls, and Eltons, Waterloo, and some of the American varieties on east and west aspects, are also well cropped. To keep up the character of the extraordinary season we are now experiencing, a terrific thunder-storm passed over us on June 18th, with a heavy hail-shower and rain. The storm seems to have been general in the midland counties and north of England; and the damage done to vegetation and the breakage of glass in hothouses by the heavy hailstones is very great in some districts. Wall fruit trees will require careful attention in trying to keep the legions of aphid and grubs in check, for I have never before seen these pests so numerous as they are at present. It is not only the loss of the crops of fruit we have to deplore this year, but likewise the foliage of the trees is now so much injured by insects, that it will affect the crops of fruit next year. On the care and attention, therefore, now paid to keeping insects down and the thinning and regulating the young wood so as to get it well ripened

will depend the success of the crop next year. In addition to hand-picking the grubs, the engine must be used freely on wall trees to try to clear them from filth. The shoots of Peaches and Nectarines should be kept nailed in as they advance, for high winds will do great damage to the young cross-growing trees. If the American blight puts in an appearance on Apple trees, a little soft soap or oil must be rubbed on the parts affected, and if this is done in time, it will effectually stop it from spreading. Thin out the canes of Raspberries where too numerous, and secure them against wind breaking them down. As early in the month as possible, and when runners can be got, the first lot of Strawberries should be laid in pots for early forcing. Perhaps Keens' seedling, if from selected plants, is as good a variety for the earliest as can be grown. President, Sir J. Paxton, and Ingram's Prince of Wales are likewise excellent varieties for succession; and Empress Engenie, Sir C. Napier, Lucas, Dr. Hogg, and British Queen for the latest crops.

Vineries.—When the grapes are all cut in the earliest houses every attention should be paid to getting the wood ripened thoroughly, and trying to get the vines into a state of rest by taking the lights off when it can be done, or exposing them to the air as much as possible. Give abundance of air night and day, and gentle fire-heat in dull weather to grapes in late vineries. All Grapes intended to be kept late in bottles of water should be well thinned, and, if possible, got thoroughly coloured and ripened by the end of September. This system of keeping Grapes in bottles is now a great fact; for many gardeners tried it last year, and have given in their adhesion to its utility. Some gardeners now say that they have tried the system nearly twenty years; but it is singular they should have let their light be hidden under a bushel so long, to the great loss of the gardening community. We have all tried to stick bunches of late Grapes in Turnips, Potatoes, and even Mangold-wurtzel to keep them for a few days or weeks, but it was not until Mr. Robinson's account appeared as to how they did these things on a large scale in France that we got on the right track. The cause of rust on Grapes has lately been discussed in THE GARDEN, and the ventilation of the subject may lead to something tangible in showing how to prevent this great disfigurement to Grapes. Sulphur has been said by some to be the great cause of the rust on Grapes; but I have never found this to be the case. To get rid of the mildew last year in a late vinery, I sulphured a portion of the vines where the mildew commenced, and the young berries were just in the stage when rusting was to be expected; but when the sulphur was syringed off, no ill effect on the berries was seen. If the sulphur was vapourized by the hot sun in summer, or by too much heat on the flues or pipes, it would doubtless affect the skin of the young Grapes if they hung near its influence. I believe the great cause of rust to be draughts of cold air sweeping over the bunches when the berries are young, rough handling in thinning the bunches, and rubbing the hair of the head on them—all of which ought to be avoided.

Peach Houses.—Where the fruit is all cleared in the early houses, give the trees a good syringing to clear the filth off the leaves collected when the fruit was ripening. In houses where the lights can be taken off, it is a good practice to expose the trees to the air, as they will make firmer wood and buds under its influence for next year's forcing. In the late houses syringing the trees and sprinkling the paths once or twice a day will all help to keep up a moist atmosphere and to keep down red spider and aphid.

Figs.—The stopping and thinning of the shoots on the trees bearing the second crop must now be attended to. Keep a moist atmosphere by frequent syringings of the trees and sprinkling the paths with water to keep down red spider.

Melons.—Still maintain a steady bottom heat by linings to dung frames, or by hot-water pipes in houses or pits. Mulch the surface of the beds with well-fermented horse droppings, the same as for a mushroom bed, and keep this well watered till the fruit begins to ripen. Melons when swelling their fruit require plenty of water at their roots, not dribblets on the surface, but a good soaking to reach the bottom roots. Sow seed now for the autumn supply of fruit, and if the plants are to be grown in pits heated with hot-water pipes, the supply of late fruit will be more certain than when grown in frames.

Cucumbers.—This will now be a good time for setting and marking the fruit of any good sort that it is desirable to keep for seed. I generally grow my plants in large pots to seed from, and after carefully impregnating the fruit leave only from three to four on a plant. By this mode I find success is more certain in getting plenty of seed true to the sort, than by trusting to fruit from plants exhausted by cropping. An excellent sort of new cucumber has been sent to me by Mr. Harrison, of Leicester, to prove for him; I have found it to be a first-class variety in size and shape, and very good in its other properties.

THE PINERY FOR JULY.

BY JAMES BARNES.

For the next four months no difficulty need be experienced in producing excellent pine-apples. The fruits will show quickly and strongly from fine healthy plants; their swelling will be greatly assisted by applications of tepid clear manure water to the roots and occasional syringings with clear soot water, together with a kindly atmospheric humidity well charged with ammonia, and a free but judicious circulation of air on all favourable occasions. Succession plants, in order to form strong healthy shoots, should be shifted on in due time, and placed farther apart in the bed; maintain a strong humid atmospheric heat, and a steady kindly bottom temperature. Syringe freely, and supply air abundantly night and day.

THE KITCHEN GARDEN FOR JULY.

BY JAMES BARNES.

ASPARAGUS BEDS keep thoroughly clear of weeds; dredge with salt moderately and often in dark and rainy weather. Of French Beans and Scarlet Runners make another sowing or two this month. Broccoli, Borecole, and Kales in variety continue to plant out as ground becomes vacant. Sow Coleworts for succession the first and third weeks of this month; as other crops are removed plant them out thickly on well-manured ground till November, in order to have abundance of sweet, crisp little heads till spring-crops come in. It is an essential matter in garden culture to have no empty space at any time through want of perseverance and forethought. Make two more good sowings of Cauliflower this month; and of this useful vegetable plant out in abundance, in order to obtain a supply of good-sized heads through the autumn and winter months. Of Celery plant out a full crop on well-prepared ground; attend well to surface-stirring, clearing away suckers, applying good soakings of manure-water to growing crops, and to methodically earthing them up as they advance in growth. During the month make two sowings of Endive and Lettuces, and plant out such as are big enough to handle. Of Radishes, Cress, Mustard, and Onions, make little but frequent sowings in light, rich soil, and on northern aspects. Where a daily supply of young crisp Turnips is required, full crops of the little quick-growing kinds may be made as Potato ground becomes empty. Onions, Parsnips, Carrots, and other root crops keep thoroughly clean, and maintain a loose open surface about them. Make a good sowing of the early Horn and Dutch Carrots twice this month on a rich light border, in order to have abundance of nice young roots throughout the winter and early spring. Continue to make plantations of Leeks, by transplanting from the seed-bed as the ground gets cleared of other crops.

Plants of Seakale that have been timely thinned will now have formed strong crowns; the flower spikes as they appear should be removed, leaving only a few of the strongest for seed. Of Peas make the two last sowings this month, choosing an early variety, and Veitch's Perfection, which is a splendid Pea, for the last crop. Prepare the ground for them by making trenches, into which dig some good rotten manure. By sowing them in these trenches their roots are more easily supplied with water, which should be given liberally should dry weather set in, for nothing is more productive of mildew than drought. Keep the whole surface of the ground between and about all growing crops well hoed and scarified, never allowing a weed a chance to appear, nor a slug peace anywhere.

NOTES OF THE WEEK.

— A FINE clump of *Brodiaea grandiflora*, a beautiful and uncommon bulbous plant, is now in flower at the Fulham Nurseries. It is a plant without which no collection can be considered complete.

— THE rare *Aquilegia californica*, perhaps the finest of all the scarlet-flowered Columbines, is now in flower at Kew. It grows there about two and a half feet high, and is very attractive. Visitors to these gardens who wish to see this fine herbaceous perennial, will find it in a bed devoted to Columbines, in the herbaceous department.

— Two of the finest hardy bulbs we have seen for a long time are now in flower in Mr. Parker's nursery at Tooting, viz., *Triteleia laxa* and *T. Murrayana*. The flowers of these are much superior to those of the spring flowering *T. uniflora*, which conveys no idea of the beauty of the sorts just named. Both are nearly equal in point of effectiveness to the African lily (*Agapanthus umbellatus*). The flowers of *T. laxa* are of a fine deep purplish blue, while those of *T. Murrayana* are of a pale purplish blue, but are produced in larger umbels. We likewise noticed *T. laxa* at Kew, and also in the nursery of Messrs. E. G. Henderson & Son.

— PRINCE ARTHUR has taken Bagshot Park, Surrey, and preparations have been commenced to render the mansion and grounds suitable as a residence for him.

— ISOLATED heads of the white Lily may now be seen peeping from among the masses of Rhododendrons in Hyde Park. This is a step in the right direction; both Lilies and Rhododendrons are greatly the better of the association. All Lilies thrive well and look well treated thus.

— IN the gardens at Heckfield Place, Winchfield, there is a beautiful specimen of *Chamaerops Fortunei*, about eight feet high, now splendidly in flower. This fine plant was transferred to the open ground in the autumn of 1867, where it has remained ever since quite unprotected, and is flourishing admirably.

— WE are happy to announce that Mr. Badger, the courteous and able honorary secretary of the Birmingham local committee, who worked so strenuously and so successfully to make the late great show a success, has been elected a Forty-Guinea Life Member of the Royal Horticultural Society. It is a small tribute greatly merited.

— A VERY charming new species of Navel Wort (*Omphalodes Luciliae*) is flowering freely in the Exotic Nursery, Tooting. The plant stood out in the open ground during the past winter, commenced to flower early in May, and has continued blooming more or less throughout the past two months. The flowers are sky-blue, with a whitish eye, changing to pink when fading.

— THE little mud-wall edgings now look exceedingly ugly in the parks. We presume they are made with a view to presenting the small succulent and other plants more effectually to the eye than they would be if placed on a level or gently-rounded bed. But this they do not do, and, being in themselves hateful and ridiculous at all times, it is to be hoped they may soon disappear.

— *EPILOBium OBCORDATUM*, a beautiful new free-flowering dwarf species of Willow-herb from the Rocky Mountains, is now in bloom on a border at the Wellington Road Nurseries, St. John's Wood. It grows about three inches high, and has flowers of a fine deep magenta or rosy crimson colour. It is one of the very finest of alpine plants.

— WE are glad to learn that the Earl of Stamford and Warrington has, with his usual liberality, thrown open his magnificent gardens and grounds to the public on Mondays, as well as Tuesdays and Fridays. Omnibuses run between Stourbridge and Enville on these days at very reasonable fares, thus affording greater facilities to the public of visiting Enville.

— THE hardy white flowered *Crinum* (*Crinum capense albiflorum*) is blooming freely this year in the Botanic Gardens, Regent's Park. This fine bulbous plant, once thought tender, is worthy of a place in all collections of hardy bulbs, the plants in Regent's Park having withstood the test of many severe winters in one of the worst clay soils with which we are acquainted.

— MR. ALEXANDER IRVINE is preparing a new work on the British plants, which he calls the "Pocket Flora of the British Islands." It is to be a condensed summary of the characters of the orders, genera, and species of our national Flora, with some illustrations, and a copious account of the localities of the rare species, and a glossarial index.

— THE Temple Gardens are now open to the public, and that boon thus granted by the Benchers is appreciated, is manifest from the numbers that flock thither every evening. The temporary closing last year consequent on the alterations necessitated in connection with the Thames Embankment, has resulted in the enlargement and other improvements of the gardens.

— MANY beds in Hyde Park are as yet (July 4th) empty and brown. We may, perhaps, expect the beds to be filled within a week or two, but the plants can scarcely make a foot of growth before they will be in danger of a visit from the earliest frosts, and if, as sometimes happens, in August, a frost should hurt our tender plants, we may at last begin to see the necessity of paying greater attention to the subjects suited to our own climate, and which do not necessitate a wintry aspect in our gardens during the bloom of summer.

— THE Royal Horticultural Society's Show at Birmingham, was brought to a conclusion on Saturday last. The day was fine, and the attendance of visitors very large. The admissions by cash payments alone were, 23,410. The amount taken at the gates during the five days was £2,476. 17s. 10d., and it is estimated that about £2,500 was realised by the sale of tickets, including the amount of £1,038 subscribed for special prizes. Something like £6,000 has been raised in Birmingham and its neighbourhood in connection with the visit of the Society. The profit is to be equally divided between the Society and Mr. Quilter, the proprietor of the Lower Grounds, Aston. Mr. Quilter has generously offered to give half his share to the charities of Birmingham.

GARDENERS' ROYAL BENEVOLENT INSTITUTION. THE ANNIVERSARY DINNER.

ON Tuesday evening last took place the most successful and pleasant anniversary which this institution has ever experienced. After the usual speeches had been made and responded to, the chairman, the Rev. S. Reynolds Hole, spoke as follows:—

Thus far, he said, we have resembled the lovers in that poem, which charms all hearts, and specially those which love a garden—the lovers in our Laureate's "Gardener's Daughter," when,—

"They spoke of other things, they coursed about
The subject most at heart, more near and near,
Like doves about a dovecot wheeling round
The central wish, until they settled there."

We come now to the main object of our meeting, and to the toast of the night. Gentlemen, there is a story told that a distinguished foreigner was brought upon a certain occasion to the anniversary dinner of the Gardeners' Royal Benevolent Institution, and that when it was delicately intimated to him by his friend that if he were disposed to increase the funds of the society a propitious opportunity had come, he did not seem to appreciate the privilege. If, he replied, as he looked around him, these are your gardeners, so healthful, so cheerful—if this is their mode of living, if thus they fare with sweet music in their ears, and their beautiful wives and sisters smiling in the distance—pardon me, *mon amie*, if I reserve my gold for objects which appear to me more afflicted and helpless than these. It was explained to him, I need hardly say, that the gentlemen present were not aged nor infirm gardeners, and that the ladies were not widows and orphans; and those true claims which this institution has upon the sympathies and support of benevolent men, were, I have no doubt, laid before him, as now, earnestly and urgently, I would ask leave to press them upon you. Ladies and gentlemen, there is no class of men which conduces so much to the happiness and enjoyment of their employers as the gardeners.

"The stately home of England,
How beautiful they stand!
Amid their tall ancestral trees,
Through all this pleasant land."

To whom, humanly speaking, do they owe so much of that beauty? To the landscape gardener! And what is now their chief grace and glory?—their gardens. What would they be—Chatsworth, Belvoir, Trentham, Hardwicke—without them? And our great merchant princes, where, when they leave the "dusky lane and wrangling mart" of commerce—where is the rest and refreshment of their lives, but in a garden? Again, is there a fête, a rejoicing, a procession, a ceremony—religious or secular—a christening, a wedding, a church to be adorned for a festival—go to the gardener for flowers. Just regard the daily gratifications which a rich man has from his garden. What is at this season, as he comes to his breakfast-table in his London house, hardly rested from last night's debate or last night's hall—what is most refreshing at his morning meal, to eye and palate too—the peach, the grape, the strawberry, sent up from his country home! It is the same at his luncheon—the succulent vegetable, the crisp salad; and at his banquet how far more beautiful than his massive plate, the pictures on his walls, the silks and satins of his guests, are the glowing fragrant flowers, the graceful ferns! and, again, the luscious fruits, which have been sent to him by his gardener. And yet again, when the dinner is over and the dance begins, more flowers for my lady's hair, for my lord's coat, for mademoiselle's bouquet; for staircase and supper-table too. I suppose that answer will be made, the man is paid for it. I speak from a long and large acquaintance with facts when I say that, with some exceptions, the gardener is not adequately paid; for these causes: 1, his vocation requires superior mental ability, as well as manual skill; 2, it involves an expenditure in the purchase of plants, and in the hospitable reception of visitors, which he cannot avoid, if he is a true gardener; and, 3, it is an occupation perilous to health. This last plea sounds the strangest, but it is by far the strongest, and the proof is but too plainly painfully manifest. At first sight you would be inclined to suppose that of all employments horticulture must be most healthful. But it is not so. In the first place, the gardener is up early and late, out in all vicissitudes of weather, and therefore peculiarly liable to that scourge of our climate, rheumatism, which cripples so many of our agricultural and outdoor workers. In the second place, a far greater risk is incurred by him again and again in the cultivation of flowers and fruits in high artificial heat. Those strawberries and grapes required the warmth of summer when snow was lying on the ground; those orchids and stove plants must have their thermometer at seventy degrees when outside there are ten degrees—twenty degrees of frost, and the gardener has to pass from one to the other, with the perspiration standing on his brow. I need hardly say that in the obituaries of our gardening publications many names are recorded, as in the case of her Majesty's gardener at Windsor, of men who perish in

the prime of life. Nevertheless, you say, though the gardener, as a rule, may be underpaid, he might reserve something to provide against these great contingencies. And this must be our opinion generally, or we should not be here to night in support of an institution of which the very aim and object is to induce gardeners to anticipate the time of need. We must all feel a surprise that—if by paying five pence a week, or one shilling and eightpence for each of the twelve months in the year, a gardener can receive sixteen pounds when he is incapacitated from work—so few comparatively subscribe to the funds. The questions are—Why do they not subscribe? How can we induce them to do so? A principal reason, I believe, which prevents gardeners from joining the institution is found in the fact that its resources do not at present insure the immediate relief of all claimants; and you would hardly expect a soldier to subscribe to a fund for the succour of the wounded, unless he knew that an ambulance and a doctor would be ready to help him when he fell. The remedy is patent: to augment the funds of our institution, so as to admit more candidates at once, and to induce more gardeners to join the institution. Masters should inform gardeners of the benefits to be derived, and do something more than tell them to save. Save, how easy to say; how hard to do! I think of my first and last money-box; how I tried to shake out the pennies not long after insertion, how I extracted them eventually with the blade of my penknife and sold my box to a friend. The way for masters really to help gardeners would be, either to pay the subscription of one guinea as partly their remuneration, or to offer to deduct it from their wages. Ladies and gentlemen, I have but few more words to say on behalf of an institution which has already relieved nearly 200 infirm and needy gardeners, and which is at this moment supporting 60 pensioners, at an expense of £850 per annum. There lives, hardly a stone's cast from my garden gate, a good, old, faithful gardener, who did his duty for forty years to my father and to me; when his strength failed, and he left my service, he had saved nothing; for his characteristic love of plants had always absorbed the little cash he had to spare. It was not in my power to support him, his wife, and daughter, or to do more than find him a home, a garden, and some small further help. What was he to do? Why to ask me to write to Mr. Cutler, of 14, Tavistock Row, to remind him that he, Evan Hirst, had subscribed for more than twenty years to the Gardeners' Royal Benevolent Institution, and to claim the pension of £16 per annum, which he has ever since enjoyed. Every day of my life I see a proof of the good done by this institution, more gratifying than words can tell. Just this more, and I cease. I said something about saving. There is only one way to save. No money which you ever spent is safe, but the dole which you gave in charity. Be generous, as in your own time of need you would have comfort. "Give, and it shall be given," for the promise cannot fail, "Blessed is he that considereth the poor and needy; the Lord shall deliver him in the time of trouble."

We have only room left to say that upwards of five hundred guineas were subscribed, and that the meeting was well attended.

SOCIETIES, EXHIBITIONS, &c.

THE BIRMINGHAM ROSE SHOW.

BY THE REV. S. REYNOLDS HOLE.

"Our old friend Horace," as many a man designates the poet whom he cordially hated in his youth, and knows only now in those fine old trusted quotations, of which the world in general, and the House of Commons in particular, seems to be never weary—Horace tells us that the man who first entrusted himself in a frail bark upon the ocean must have had a heart of oak and a bosom of brass; and most of us, remembering the time, when, with a mighty effort of self-command, we left the banks of our family duck-pond in tremor of spirit and in a wobbling tub, can verify all that he says. And all who embark upon a new enterprise must possess this bravery, if ever they hope to make a prosperous voyage, and to reach the shore in safety—he, especially, the young and ambitious amateur, who is about to launch upon the Red Sea of Roses, and to seek the haven of success and honour. He must be prepared, like the mariner, for storm and sickness. Like the boy in the brewing-tub, he must never lose courage, or he will assuredly upset his vessel, and find himself sticking in the mud.

He, who proposes to grow and show the rose in its beauty must prepare himself for many difficulties and many disappointments, and must never flatter himself that because he has a good soil, a good situation, healthful rose trees, and plenty of

manure (all indispensable elements of rose culture), that he has entered upon safe and tranquil seas. Frosts in the winter, and, far more fatal, frosts in the spring, caterpillar, aphid, mildew, fungus, rain-storms, hail-storms, wind-storms, and thunder-storms, must be in his prevision always, and, so far as watchful care can aid, in his prevention too. Thus, and only thus, doing his best, and not daunted because, doing his best, at first he fails, he shall advance, I promise him, from an "extra prize" to a fourth, from a fourth to a third, from a third to a second, and from secondary to primal honours.

Consider the adversities which have so recently met the rosarian in the cruel frosts of May and in the drenching deluges of June, and then regard the glorious display of roses at Birmingham in proof of what I have said; and let nurserymen remember that it is not because Messrs. Cant, and Turner, and Paul, and Veitch, have better soil, but because they have the spirit of perseverance, vigilance, and love, that they have triumphed; and let amateurs be assured that Messrs. Evans, Laxton, and Perry have no mysterious secrets—only a more patient and a more earnest devotion to the rose. Again and again these heroes, victorious now, have endured disappointment and defeat; but, like true knights and wise generals, they have only learned from the failure of to-day how they may best insure to-morrow's victory.

The best roses in the exhibition were shown by Mr. Cant, of St. John's Street, Colchester, and by Mr. Turner, of the Royal Nursery, Slough, the former winning the first prize for seventy-two varieties, and the latter the first for forty-eight, and also the first for twenty-four. Very grand roses they were, both as to brilliancy of colour and as to fulness and symmetry of form; and the amateur will do well to read carefully the names of the successful flowers, and to order those which he does not possess. Mr. Cant also achieved the first prize for twelve blooms of the same rose, with a wonderful collection of "Dupuy Jamain," the most striking flower in the show as to colour, which so glowed with a violet and carmine splendour, that it almost seemed to be surrounded with a halo. His rivals gleamed with all their rich crimson tints, but he eclipsed them all save one, the Duke of Edinburgh, which, grown by the same exhibitor, took the premier prize as the best single rose in the show. Mr. Cant was also victorious with his beautiful blooms of Countess of Oxford, in "the best new rose sent out by English nurserymen in the spring of 1870 or 1871."

In addition to the high honours previously referred to, Mr. Turner, of Slough, also won the first prize for "twelve trusses of white or blush roses, all of one variety," with a dozen lovely specimens of the Baroness Rothschild.

Mr. George Paul, of the firm of Paul & Sons, the Old Nurseries, Cheshunt, was not in his usual "form"; but after winning some seventy prizes in 1871, and the principal premiums for pot roses in the spring of 1872, his temporary halt on the road to victory need cause him small discomfort, and indeed he is one of the few successful heroes of horticulture who bear defeat with perfect complacency. Not that he won no glory in this great war of the roses. To be second in the great race of all, first for new roses, and first for roses in pots (the latter one of the most charming features of the show), was enough to transport the ordinary rosarian into a wild delirium of joy; but great marshals may not be satisfied with the brilliant charge of a regiment, nor even with the success of a brigade; and that which is a banquet for the dolphin is but a breakfast for the whale.

I was glad to see that Messrs. Veitch & Sons, who gave me brotherly help in establishing the first national rose show, had made great progress in the quality of their cut roses. They evidently aspire to that pre-eminence in roses which they hold in the introduction of new and beautiful plants; and if they make as much improvement in the next two years as they have made in the two which are past, the high-mettled racers who run for Queen Rosa's Plates must keep themselves in condition, for they will certainly want all their speed.

Two of our chief rosarians were not competing. Mr. Cranston, of Hereford, brought some boxes of cut blooms for the ornamentation of the show, the bulk of his plants not being in flower, and Mr. Keynes, of Salisbury, has still his triumphs in prospect.

The amateurs were not quite in their usual force; but Mr. Laxton, of Stamford, Mr. Perry, of Castle Bromwich, and chiefly Mr. Evans, of Arbury, exhibited some excellent roses. I was pleased to notice that, though my dear old companion, the Rev. Patrick Smythe, of Solihull, is "lost a-while" to us, his successor is doing ample justice to the rose trees, which he loved so well.

Some of my friends who did not attend the show, may desire the names of those roses which seemed to be the best. There were among the older varieties:—Alfred Colomb, Baroness Rothschild, Beauty of

Waltham, Centifolia Rosea, Charles Lefebvre, Devoniensis, Duke of Edinburgh, François Louvat, General Jacqueminot, Henri Ledechaux, John Hopper, Madame Boll, Madame Caillat, Madame C. Joigneaux, Marguerite de St. Amand, Marie Beauman, Maurice Bernardin, Madame Villermoz, Maréchal Niel, Monsieur Noman, Monsieur Bonnefines, Madame Therese Levet, Marechal Vaillant, Madame Bravy, Nardy Frères, Pierre Notting, Senatenr Vaisse, Victor Verdier, and Xavier Olibo; and among these of more recent introduction, Countess of Oxford, Dupuy Jamain, La France, Louis Van Houtte, Mille. Eugénie Verdier, Marquise de Castellane, and Paul Neron.

Of the roses sent out in May last, the following appear to me to be the most promising:—Baronne Louise Uxkull, Etienne Levet, Jeanne Gros, Lyonnais, Madame George Schwartz, President Thiers, and Richard Wallace. I also admire Mr. George Paul's "Annie Laxton," which was raised by that clever and enthusiastic florist, Mr. Laxton, of Stamford, and which has received a first-class certificate. In vain I endeavoured, as one of the judges and as a member of the floral committee, to obtain a similar distinction for a beautiful new English rose, raised by Mr. Curtis, of the Devon Nursery, Torquay, from a "sporting shoot" of Abel Grand, and called by him "Bessie Johnson," but I was opposed and frustrated by a member of the council of the Royal Horticultural Society, who, having first informed me that he had the power of recommending the rose for a certificate, refused, on seeing it, to do so, for reasons which he did not assign. Mr. Curtis may console himself with the conviction that the public will endorse my estimate of his rose (I heard a nurseryman, Mr. Standish, of Ascot, order a dozen of plants as soon as he saw it; and I know that many other rosarians admire it greatly); but it is a great injustice to grant certificates, as the Royal Horticultural Society has frequently done, to roses raised in France, and not belonging exclusively to the purchaser, who has sent them for inspection, and then to refuse encouragement to a *bona fide* English flower, of symmetrical form, of excellent habit, of a colour which we most desiderate, namely, a pale blush, and of a fragrance hardly surpassed by any rose in cultivation.

ROYAL HORTICULTURAL SOCIETY'S ROSE SHOW. (JULY 3RD.)

SELDOM have we seen the Queen of Flowers shown better than on this occasion. Nurserymen and amateurs keenly contested, and both exhibited blooms of sterling merit. The freshness of the flowers was quite captivating, and when shown in threes, accompanied by a few leaves, they were highly effective. There was only one collection in pots, and that was furnished by Messrs. Paul & Son, the excellence of whose flowers, notwithstanding the lateness of the season, was something remarkable. In the nurserymen's class of seventy-two cut blooms distinct kinds, equal first prizes were awarded to Messrs. Paul & Son, and to Mr. Cant, of Colchester. Other classes were equally well represented. In the amateurs' collection, some showed their blooms to better advantage than others by raising them a little above the moss; thus situated they look much better than when laid flat on the surface. Amongst the best roses brought forward at this show may be mentioned Alfred Colomb, Senatenr Vaise, Queen Victoria, Xavier Olibo, a fine dark velvety red, Duke of Edinburgh, Louis Van Houtte, a fine dark kind, Maréchal Vaillant, Baroness Rothschild, Baron Rothschild, a beautiful flower, Prince Camille de Rohan, and Alfred de Rougement, an exceedingly fine dark coloured velvety sort. In single trusses in bud, Messrs. Veitch & Sons came off first with some pretty examples of Homer, which, from its peculiarly delicate colour, appeared quite striking amongst its associates, Madame Falcot, Mons. Furtado, Souvenir de Elise, Devoniensis, and Niphetos. Prizes were offered for good sweet-scented Roses (exclusive of Teas and Noisettes), but they did not bring forward the competition one might have expected. First in this class was Mr. Keynes with a stand of six blooms of La France. The same exhibitor also took another first prize for the best sweet-scented Tea or Noisette Rose with Devoniensis.

New Roses were not plentiful. Messrs. Paul & Son furnished Annie Laxton, a beautiful pink; W. Wilson Saunders, a fine double dark coloured kind; Princess Christina, a good closely bloomed pink variety; and Reynolds Hole, a dark, velvety, double flower, certainly one of the finest, if not the very finest Rose in the show.

First-class certificates were awarded to *Lilium Humboldtii*, a beautiful deep orange-coloured kind with very distinct small spots regularly distributed over the petals, which are a good deal reflexed; to *L. Martagon dalmaticum*, a small flowered dark brown or rather bluish-purple kind, quite distinct from anything which we have hitherto had; both of these came from G. F. Wilson, Esq. Similar awards were also made to *Macrozamia corallipes*, and to *Echeveria scapophylla*, a hybrid between *agavoides* and *linguaefolia*, from Mr. W. Bull; to Rose Annie Laxton, from Messrs. Paul & Son; to *Verbena Lady of Lorne*, white shaded with purple, and producing fine large trusses, from Messrs. W. H. Staacy & Son; to pyramidal Stock Mauve Beauty, from Mr. R. Dean, of Ealing, a fine double kind; and to the following *Pelargoniums*, viz., Empress and Gem of Tricolors, both tricolor kinds from Mr. C. Kimberley, Stoke, near Coventry; Argus, an ivy-leaved kind, from Mr. G. Smith, Hornsey Road; and to a beautiful tricolor, named Mrs. Laing. Several miscellaneous subjects were also shown.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE HORTICULTURAL "CONGRESS" AT
BIRMINGHAM.

CIRCUMSTANCES have till this year prevented me from attending any of the provincial congresses of the Royal Horticultural Society, and I regret to say I have been anything but edified by the one that has just taken place. A roomy tent is occupied at one end by a few dozen persons of the gardening fraternity, the rest of the space being filled more or less by visitors to the show driven in by passing showers. At hand there is a great noise, which to those not very acute of hearing seems to be the distant sound of the cheers of inebriated men; but it is explained by the immediate proximity of the poultry show. The chairman, Lord Bradford, is absent; and, after some delay, Mr. Moore begins his paper on "Recent Progress in Practical Horticulture." This, curiously enough, had nothing to do with what deserves the name of "progress" in horticulture, but was a mere list of our latest plant introductions and most meritorious seedlings. The list, like all Mr. Moore's work, showed his wide and exact knowledge of the various types of garden vegetation; but was, after all, simply the sort of thing published towards the end of the year by our gardening contemporaries. To this we have, perhaps, no right to object; but on an occasion of this kind, when there is so much to SEE, and when most of us have to go home before we have half completed our survey, it is scarcely considerate to induce us, by "taking titles," to listen to such a well-known *résumé*. Several reporters attended the "congress," and awaited the beginning of operations with the usual attentive attitude which these gentlemen assume; but after a few minutes they laid down their pencils, soon to disappear altogether. Mr. Wm. Paul read a sensible paper on tree form, and several other papers were read, for the discussion of which there was no time to spare.

On the first day Professor Dyer read a paper on some points in connection with the scientific side of horticulture, and on the second Mr. Moore read his paper above alluded to.

The accuracy of the division of the subjects into "scientific" and "practical" may be judged from the lists of papers, which were as follows:—

THE FIRST, OR "SCIENTIFIC," DAY.

The Botany of the Neighbourhood of Birmingham.

On the Relative Influence of Parentage in Flowering Plants.

On some Thermometers for Horticultural use.

On *Dracæna* and *Cordyline*.

On Sulphozone.

On the use of Glass and other Protective Materials in Horticulture.

On Canker in Fruit Trees.

There is, of course, no more distinction in the nature of these subjects than among apples from the same orchard. No notice whatever was given of what papers were to be read, and no one was prepared to discuss them. As we presume those who read the papers did not intend them for the special information of the few dozen persons who attended the meeting, it would be very desirable to make provision to place such papers at once at the disposal of all who care to print them. As it is, one of our contemporaries only is aware of what papers are to be read. It is to be hoped that this one-sidedness merely requires to be pointed out to be remedied.

At the end of Mr. Peach's paper on bedding out, the Rev.

THE SECOND, OR "PRACTICAL," DAY.

On Form in the Tree Scenery of our Gardens, Parks, and Pleasure Grounds.

Hints on the Formation and Arrangement of Shrubberies.

On the Bedding-out System.

On *Stapelias*, their Culture and Peculiarities.

The Future of our Fruit Crops.

On Alpine Plants.

The Cottage Garden.

Reynolds Hole asked permission to say a few words, and was informed that he might do so "for three minutes." Mr. Hole began by remarking that however agreeable the mixture of poultry and gardening information might be in a journal with which most of his hearers were well acquainted, he did not think the immediate neighbourhood of such a vast collection of cocks and hens exactly the right place for a horticultural congress. He then indignantly protested against the erroneous division of the subjects of the "congress" into "scientific and practical" so called, and very justly stated that if any such arbitrary divisions were necessary, the gardeners—those who produced the display—those who worked heart and soul in the art, for the encouragement of which the Royal Horticultural Society was founded, and by which it lives—were entitled to the precedence.

Remedies for the state of things above pointed out at once suggest themselves. A subject of great importance should be selected for sole discussion at each annual meeting, and one or two able papers should be read upon it by competent persons. These papers should not be mere incoherent scraps, nor need they be long to weariness. A free discussion might follow. The subject should, of course, be made known long beforehand. Then all interested would be prepared, and if the theme were well selected, and had a prospect of being discussed in a proper manner, it is probable that numbers would be attracted to the exhibition, mainly by the congress. The whole might of the horticultural mind would be brought to bear on the subject for months beforehand, and we might look for some really fresh and stimulating views or facts; at least we should be certain of a very pleasant meeting.

Then, again, the congress should be held in the evening, and in some suitable building in the town near where the exhibition takes place. These shows are so large, that for those who can spare one day or those who can spare six, all our time is required for seeing the many beautiful and novel objects brought forward. Therefore many can ill spare a few hours in the day time, who could easily attend an evening *réunion*. Lastly, the subject should not only be purely horticultural, but of the highest horticultural importance. The aim and object of the Society should never be forgotten.

We do not hear of builders, or engineers, or architects, or artists, assembling to listen to essays quite foreign to their respective arts or sciences. Perhaps the intrusion of such subjects at our gardening meetings accounts for the absence of the class the meetings were intended to enlighten.

It would certainly be better to give up these congresses altogether, or make a bold effort to put life in them. These remarks are not intended merely as applicable to the present congress, or to the management of it by the learned gentleman, the professor of botany of the Society. He, there is reason to believe, greatly desires the improvement of the congress, which, as everybody knows, has been a *fiasco* from the beginning, before his connection with it. To go on as at present, will not merely be a loss to horticulture, but a disgrace to it.

H. N.

The Parcel Post and the Transit of Plants and Cuttings—

The advantages and economy of the facilities now offered by the post-office for sending parcels safely and cheaply by post can hardly be over-estimated by amateur gardeners and others fond of flowers, but hitherto prevented from indulging their tastes except in the most meagre way, because of the expense and trouble of procuring flowering plants. To those who reside at a distance from florists and nurserymen, and in the country generally, and who are therefore prevented from making personal visits of inspection and carrying off their purchases with them, the parcel post is the greater boon. They are now saved the anxiety and vexation caused by delays and their consequences, and receive their parcels with all the certainty and despatch which reflect so much credit on our postal system and its administration. Many nurserymen and florists in different parts are giving their customers and the public the full benefit of this facility, by preparing and packing plants and cuttings to be sent by parcel post. This fact is not yet so widely known as it should be, especially in rural parts, and we are only doing our duty in drawing the attention of our readers to it. We can assure them that the method is both safe and economical, a saving being effected not alone on the carriage, but also on the prices of the plants.

NOTES OF THE WEEK.

— WE learn that Mr. James Backhouse, of York, the indefatigable observer of our British alpine plants, has discovered *Cystopteris alpina* in the north of England.

— THE flowers which the orange trees in the gardens of the Tuileries and Luxembourg will bear this year, are now being sold in Paris by public auction.

— THAT fine shrub *Fremontia californica*, is now forming seed-pods in the Coombe Wood Nursery; it has been flowering abundantly for the past eight weeks.

— A COLLECTION of Italian cottons, in the raw condition, has been formed by the Chevalier Jervis, Curator of the Industrial Museum, Turin, and sent to the cotton department of the International Exhibition, with a map showing the districts in Italy where the cotton is under cultivation.

— *DICENTRA CHRYSANTHA* is one of the finest herbaceous plants we have had for a long time. It is now covered with its golden yellow flowers, which contrast beautifully with the glaucous green foliage. The plant is about four feet high, and as much through, and is a mass of bloom from bottom to top.

— AN attempt is being made to acclimatise in Europe the New Grenada *Coriaria thymifolia*, or ink plant. The sap which flows from this plant is called *chanchi*; it is reddish at first, but afterwards becomes intensely black. This ink can be used without any preparation, and does not injure steel pens as much as ordinary ink, while, at the same time, it is more enduring.

— THE night-blooming *Cereus* (*C. grandiflorus*) has been lately flowering in great perfection in Mr. Ceely's conservatory, at St. Mary's, where on some nights it opened as many as twenty flowers. As most of our readers doubtless know, the flowers of this and some other nearly-allied species of *Cactas* only come forth at night, and their existence is limited to one night; on the following morning they close up, and are seen no more.

— Two handsome species of Flax, introduced by Messrs. Backhouse, of York, about two years ago, are now flowering in the neighbourhood of London. They are *Linum salsoloides* and *L. viscosum*. The first has narrow heath-like leaves and white flowers with a purplish eye and is growing on the rockwork at Kew; *L. viscosum* may be seen at the Hale Farm Nurseries, Tottenham; it has downy leaves and pale purplish rose-coloured flowers, which are produced in great abundance.

— WE have just received from the Rev. Harper Creve one of the most beautiful flowers we have ever seen. It is a large pure white single rose, supposed to be of Russian origin. At first sight it seemed like a very large flower of the *Gam Cistus*. It has a delicious and somewhat peculiar scent. We hope that the presence of so many fine double roses in our garden will not be considered a reason for not growing this and some others of the fine single kinds. The plant flowered in Mr. Crewe's garden at Drayton-Beauchamp, and is of course quite hardy.

— SEVERAL gentlemen of New York city have projected the establishment of a botanical garden in Madison Avenue, where there is to be erected a substantial and ornate glass and iron structure for the reception and exhibition of plants from all parts of the world. It is proposed to make this not only a perpetual plant exposition, and hence a place of public resort, but to establish in connection therewith a school of botany.

— LILIES are now in all their glory of bloom in our gardens. The much-admired *Lilium auratum* is flowering as freely in the open air, in beds of peaty or other light soil, as the common orange Lily of our cottage gardens, though the severe season we have had has been unusually hard upon them. In Mr. Wilson's garden, at Weybridge Heath, where there is such a fine collection of Lilies thoroughly well-grown, long and vigorous shoots of *Lilium speciosum* and its varieties, are now shooting forth here and there from a bank of *Rhododendrons*, and by and bye will be very beautiful seen in that position.

— THE Liverpool Improvement Committee have recommended that the rockwork required at the road crossing the valley at Sefton Park should be executed at 25s. per cubic yard, the amount not to exceed £75. Confirmation of this recommendation having been moved, Lieut.-Colonel Steble said that although the amount was small, he should like to know that this was the last of the recommendations as to the ornamentation of the park. Alderman Weightman said the first estimate of Messrs. André and Hornblower for the work was £1,500; this was reduced by the sub-committee to £800, and if the present recommendation was agreed to, the amount would be reduced to something like £200. The committee were desirous of reducing the expenditure on the park as much as possible.

— THE pretty *Callistemon rigidum*, a shrubby plant from Australia, is now flowering freely, trained against a wall in the Royal Gardens, Kew, a position in which it has stood for several years.

— WE understand that her Majesty, the ex-Empress of the French, visited Messrs. Jackman's nursery at Woking the other day to see their fine collection of Clematises, which are now coming into full bloom.

— THE march of improvement will, we hope, never cease, and it has at last reached Golden Square, Soho. We were glad to see some fine masses of lilies warming up the old square with bright colour the other day.

— A FRENCH writer says that *Centranthus macrospilon* makes an excellent salad. Salad-famine during the war led to its discovery, or rather to its use. The plant is an annual, well known to growers of annual flowers.

— A PRETTY species of Loose-strife (*Lythrum flexuosum*) is flowering at Mr. Ware's nursery, Tottenham. It is a rare species, growing from six to nine inches high, and produces a profusion of rosy-purple flowers.

— MR. PEACOCK'S magnificent collection of succulents is gaining for itself a world-wide notoriety. It formed a remarkable feature of the Royal Horticultural Society's show at Birmingham; and this week it has been visited by the distinguished foreigners from Burmah now amongst us.

— THE cultivation of the poppy in France is steadily increasing; it now occupies about 50,000 acres, of the value of 4,500,000 francs, yielding opium to the value of 2,000,000 francs per year. Different samples of opium raised in various parts in Europe yield from eight to thirteen per cent. of morphine.

— PRINCE ARTHUR, on the invitation of the Corporation of Leeds, has, we understand, consented to visit that town on September 19th, when he will open Roundhay Park, which has been purchased by the Town Council for a people's park. It is 600 acres in extent, and has been purchased at a cost of £139,000. It contains a magnificent lake, covering thirty-six acres.

— ROCHESTER CASTLE GARDENS were opened to the public the other day by the mayor, in the presence of a large company. The gardens have been taken on lease by the Corporation from Lord Jersey. A public subscription has been raised for the purpose of laying them out and for other work, which has already cost more than £2,000. We gave a view of the design, which is wretched in the extreme, some time ago.

— LOVERS of alpine plants will be glad to learn that our esteemed correspondent, Mr. J. C. Niven, of the Hull Botanic Gardens, is to edit another volume of "Alpine Plants," the work begun by Mr. Wooster. This is fortunate, both for the book and the cultivator of these charming flowers, as Mr. Niven has devoted many years of loving attention to them, and it would be difficult to find anybody so well qualified to write on them.

— How beautiful are the rock roses now! And well-named "rock roses," for no single rose exceeds them in bright beauty of colour and profuse flowering qualities. They are happiest on poor, light, and dry soils, but thrive in any well-drained soil. They are among the finest of our neglected shrubs. We hope somebody with a garden on a warm soil will study the family thoroughly, and find out for us how many kinds will really survive on ordinary soils.

— THE most beautiful hardy shrub now in flower in our gardens is the white *Spiræa arifolia*. Its elegant flowers, seen among our common shrubs, seem like tossed spray on a sunny sea. At present such noble shrubs are usually thrust into a shrubbery, and there allowed to take their chance. Obviously such fine subjects would look much better isolated on the turf, or associated in small irregular groups, so that each might show its character, and the whole have a picturesque effect. When we pay as much attention to tastefully arranging such noble and long-lived shrubs as we do to those which last only a few months in beauty, we shall find a rich reward.

The Nine Hours' Movement.—The world has sympathised with this movement. Now let the world read the following advertisement, which appeared the other day in a London paper:—"Covent Garden Market, Central Avenue.—Wanted, immediately, four or five strong, active, healthy, hard-working girls for bouquet-making, &c. Early risers indispensable. Usual hours of business from five o'clock a.m. until eleven o'clock p.m. Applications to be made to the Florist's." From five a.m. to eleven p.m. is not nine but eighteen hours, leaving six hours a day for exercise, sleep, toilet, improvement of the mind, home life, and recreation. How long would a "strong, active, healthy, and hard-working girl" hold out at such work, and what kind of human creature would she be after about five years of it?

Plants in this list are almost without exception such as have come into bloom during the past week.

PRIZE ESSAY ON THE POTATO CROP.*

BY GEORGE MAW, F.S.A., G.S., L.S.

The striking evidence obtained from a few experiments made during the year 1864 with the object of ascertaining the sized potato-set most profitable to plant, induced me during the past year to carry out a more extensive series on a systematic scheme. 129 trial plots were arranged with special reference to the following questions, which I propose to consider under separate heads:—

1. As to the influence of the size of the set on the economic results of the crop; *i. e.*, whether any increase, and to what extent, is obtained over and above the extra weight of the set, in the planting of large in lieu of small sets.

2. As to the influence on the crop of the distance at which the

* "Results of Experiments on the Potato Crop, with reference to the most Profitable Size of the Sets, the Influence of Thick and Thin Planting, &c." Prize Essay. By George Maw, F.S.A., G.S., L.S. Extracted from the *Journal of the Royal Agricultural Society*.

sets are planted; or the results of close and wide planting of various sized potatoes.

3. As to the comparative results from planting similar weights of large and of small potatoes per acre.

4. As to the relative advantages of cut and whole sets.

5. As to the influence of thick and thin planting, and of the size of the set, on the proportion borne between the weights of the sets and the weight of the crop, and the rate of increase under various conditions.

6. As to the relative productiveness of different varieties of potato.

Much diversity of opinion seems to prevail on these points, which are of economical importance in relation to both the farm and garden cultivation of the crop. The selection of the potato-sets appears commonly to be more a matter of present expediency than prospective profit. The general course is to appropriate the largest for use, the very smallest for pig-feeding, the tubers of intermediate size being preserved for replanting; this method of assortment results in the use of sets of from two to three ounces in weight, and a set of less than two ounces is as often planted as one exceeding three or four ounces. Our primary question is whether an increase in the size of the set will produce an excess above the extra weight of the sets planted; such extra weight going to increase the strength of the individual sets without increasing their number?

Every precaution was taken to insure the most perfect uniformity in the conditions under which the various experiments were made. The manure was separately weighed out, and distributed on each twenty superficial feet of ground. The distance—two feet—between the rows was the same throughout the trial ground; and to counteract the influence of any slight variations in the character of the soil, the particular experiments that would be brought into immediate comparison were placed as nearly as possible in juxtaposition. External rows were rejected for the experiments, and planted with part of the ordinary crop; and every individual set was separately weighed and selected to the specified size, and planted to measure, at precise distances.

Notwithstanding these precautions, there was a want of correspondence in many of the individual results, which I would notice as a warning against depending on the evidence of single experiments: for instance, in plots planted under precisely the same conditions, and with no apparent difference in the appearance of the crops, the produce varied to the extent of several tons per acre. Similar inequalities, apparently unaccountable, will be found in all agricultural crops, and in the conduct of experiments every care should be taken that they are fully recognized in the calculation of results. Under the head of "Accidental Variations of Result" at the end of the report, I shall consider this subject more in detail, and endeavour to show the extent to which these adventitious irregularities affect the general tenor of the experiments. It remains now to consider separately the various points to which the experiments relate.

It will be found that I have in no case relied on isolated results, but drawn the conclusions from the general bearing of the series. Throughout the report the term "gross crop" will apply to the whole weight of potatoes produced per acre, and "net crop" to the balance of produce after deducting the weight of the sets from which it was grown.

1. The influence of the size of the set on the economic results of the crop; or whether any increase, and to what extent, is obtained over and above the increased weight of the set in the planting of large in lieu of small sets:—Several separate series of experiments may be cited in evidence of the influence of the weight of the set on the produce of the crop. An average of from ten to thirteen experiments with different varieties, planted one foot apart in the rows, gave the following results:—

Gross Return per Acre.

		tons.	cwts.	qrs.	lbs.	ozs.	
Average of 13 varieties,	1 oz. sets	10	19	3	17	or	17'65 per set.
"	2 oz. sets	12	15	2	14	or	21'03 "
"	4 oz. sets	15	17	2	15½	or	25'39 "
"	6 oz. sets	20	16	1	9	or	33'44 "
"	8 oz. sets	23	8	1	14	or	38'67 "

After deducting the weight of the sets, the net balances of produce per acre will stand as follows:—

		tons.	cwts.	qrs.	lbs.	ozs.	
Average of 13 varieties,	1 oz. sets	9	17	3	0	or	16'65 per set.
"	2 oz. sets	11	11	1	7½	or	19'03 "
"	4 oz. sets	13	9	0	2½	or	21'39 "
"	6 oz. sets	16	13	1	16½	or	27'44 "
"	8 oz. sets	18	11	0	16	or	30'67 "

The following are the amounts of net profit per acre for *each oz.* in the increase in the weight of the sets, from 1 oz. up to 8 ozs. (each

oz. in the weight of the set occupying 2 square feet, being equivalent to 12 cwts. 17½ lbs. per acre) of seed:—

	tons.	cwts.	qrs.	lbs.
From 1 to 2 ozs.	1	13	2	7½
„ 2 to 4 ozs., for each extra oz.	0	18	3	14
„ 4 to 6 ozs. „	1	12	0	21
„ 6 to 8 ozs. „	0	18	3	14

The average of a number of experiments with different varieties planted 9 inches apart in the rows, gave very similar results as follows:—

Gross Returns per Acre.

	tons.	cwts.	qrs.	lbs.	ozs.
Average of 11 varieties, 1 oz. sets	10	12	0	23	or 14'21 per set.
„ 12 „ 2 oz. sets	15	2	2	11	or 18'45 „
„ 6 „ 4 oz. sets	17	17	3	12	or 21'99 „

After deducting the weight of the sets, the net balances of produce per acre stand thus:—

	tons.	cwts.	qrs.	lbs.	ozs.
Average of 11 varieties, 1 oz. sets	9	16	0	0	or 13'21 per set.
„ 12 „ 2 oz. sets	13	10	0	21	or 16'45 „
„ 6 „ 4 oz. sets	14	13	0	4	or 17'99 „

The average produce of a number of varieties planted at intervals of 6 inches in the row, also exhibited similar advantages in favour of the larger sets, viz.:—

Gross Returns per Acre.

	tons.	cwts.	qrs.	lbs.	ozs.
Average of 11 varieties, 1 oz. sets	13	4	1	20	or 10'85 per set.
„ 10 „ 2 oz. sets	15	19	0	12	or 18'15 „
„ 3 „ 4 oz. sets	22	0	2	3	or 18'11 „

After deducting the weight of the sets the net balances of produce per acre stand thus:—

	tons.	cwts.	qrs.	lbs.	ozs.
Average of 11 varieties, 1 oz. sets	12	0	0	13½	or 9'85 per set.
„ 10 „ 2 oz. sets	13	10	1	27	or 11'15 „
„ 3 „ 4 oz. sets	17	3	1	5	or 14'11 „

Every step in each of these three series of experiments gives, without an exception, unequivocal evidence that each increase in the weight of the set produces more than a corresponding increase in the weight of the crop. The following statement will, however, show that the advantage in the employment of large sets is much less striking in the early than in the late varieties; out of the examples before given the produce of the early varieties, planted one foot apart in the row, exhibit the following result:—

	Gross Crop.				Net.			
	tons.	cwts.	qrs.	lbs.	tons.	cwts.	qrs.	lbs.
Average of 7 early varieties, 1 oz. sets	9	3	3	26	8	11	3	8¾
„ 7 „ 2 oz. sets	10	14	2	17	9	10	1	10½
„ 6 „ 4 oz. sets	13	19	0	7½	11	10	1	22½
„ 6 „ 6 oz. sets	15	6	0	22	11	13	1	2½
„ 2 „ 8 oz. sets	7	17	0	21	2	19	3	23

Although there is throughout an increase over and above the extra weight of the sets, the advance between the larger sizes is not very marked, and is much below that wherein the early and late sets are averaged together. There is even a falling off in the produce of the 8 oz. sets, in comparison with those weighing 6 ozs.; but this is partly from accidental circumstances; the 8 oz. sets being much sprouted before planting, indeed all the larger sets of the early varieties were much more advanced than those of smaller size. After separating the early sorts from the general average results of early and late, the average produce of the late varieties, taken separately, will stand as follows:—

	Gross Crop.				Net.			
	tons.	cwts.	qrs.	lbs.	tons.	cwts.	qrs.	lbs.
Average of 6 late varieties, 1 oz. sets	12	0	0	15	11	7	3	26
„ 6 „ 2 oz. sets	15	3	1	19	13	19	0	13
„ 6 „ 4 oz. sets	17	16	0	24	15	7	2	11
„ 3 „ 6 oz. sets	30	6	2	11	26	13	2	19
„ 4 „ 8 oz. sets	31	3	3	24	26	6	2	26

(To be continued.)

Advertising Cabbage Seeds.—Millard, the banker and newspaper speculator, who died a little while back in Paris, and who founded the Paris *Petit Journal*, which at one time had a daily circulation of nearly half a million copies, was an enthusiastic believer in the advantages of liberal advertising. One day he had at his table nearly all the proprietors of the leading Paris dailies. They conversed about advertising. Millard asserted that the most worthless articles could be sold in vast quantities, if liberally advertised. Emile de Girardin, of *La Presse*, who was present, took issue with him on the subject. "What will you bet," exclaimed Millard, "that I cannot sell in one week one hundred thousand francs' worth of the most common cabbage seed under the pretext that it will produce mammoth cabbage heads? All I have to do is to advertise it at once in a whole-page insertion of the daily papers of this city." Girardin replied that he would give him a page in his paper for nothing if he should win his wager. The other newspaper publishers agreed to do the same thing. At the expiration of the week they inquired of Millard how the cabbage seed had flourished. He showed them his books triumphantly, and satisfied them that he had sold nearly twice as much as he had promised, while orders were still pouring in; but he said the joke must stop there, and no further orders would be fulfilled.

THE PROPAGATOR.

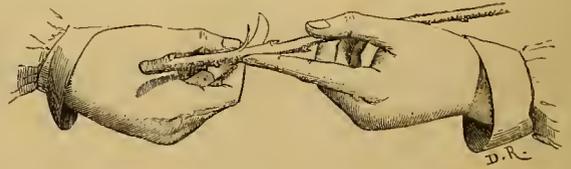

THE ART OF GRAFTING.

(Continued from Vol. I., p. 713.)

GROUP 4.—CLEFT-GRAFTING.

GENERAL DIRECTIONS.—This method is employed for propagating the greater part of woody deciduous trees and plants. The scion is a portion of a branch furnished with one eye or several. For a young stock a short scion is to be preferred. If the stock is a large tree, in a cold but rich soil, and in a damp climate, scions with four or five eyes are preferable to shorter ones; while, on the other hand, in poor soil, and in a warm dry climate, short ones are best.

Let us take a medium-sized one, with two or three buds, and three or four inches in length. In preparing it, we cut the lower part on two sides, so as almost to resemble two sides of a triangle. We say *almost*, as the two sides do not meet in a sharp edge until near the point; a strip of bark being often left, which gradually widens from the point to the top of the cutting. Opposite this edge is the back of the cutting (which is not touched with the knife), commencing immediately under an eye, and ending in a point at the lower extremity of the scion. In some cases we shall see that we can continue to have a bud on the back of the cutting; and in some modes of cleft-grafting the scion is cut with an even face on both sides, instead of being wedge-shaped or

Preparation of the Cleft-Graft.

triangular in form. When it is desired to set the scion evenly on the stock, a small horizontal or oblique notch is cut on each side at the top of the sloping cut. The preparation of the scion is effected more easily by holding it extended along the forefinger of the left hand. With the grafting-knife in the right hand, it is cut and smoothed down on both sides; the least inequality or roughness would be an obstacle to its perfect coincidence with the stock; the point should be slightly blunted in order to facilitate its slipping in smoothly. We may remark, as a useful hint to beginners, that the operator has more power and command of his implement if he keeps his elbows close to his sides. Whether the stock be entire or provisionally headed down, it is finally cut at the moment of the operation at the place destined to receive the graft, in order that the grafting may be performed on a freshly-cut surface. When the saw or the sécateur is used for this purpose, the cut is smoothed down with the pruning-knife, so as to remove all inequalities from the surface. If the stem is of medium thickness, not more than one graft is made on it, and the cut is made in a slightly oblique direction; but if the strength of the stock requires several grafts, then the cut is made horizontally (for crown or cleft-grafting). Cleft-grafting is effected with one or several scions; the various processes consist in employing them either when woody or herbaceous; in spring, summer, or autumn on the body of the tree, on the top, or at the angle of the branches.—*C. Ballet.*

(To be continued.)

Grafting-Wax.—This is an article that everybody should keep on hand, ready for use whenever needed, for it is valuable for various other purposes besides that of grafting. Wounds made in pruning large trees will heal over much sooner if coated with this wax; and if a piece of bark is accidentally stripped from a tree, the place should be covered over with it, and the wood will remain sound and healthy underneath. There are several receipts for preparing this wax, and I have found the following better than any one tried:—Melt in a basin one pound of tallow, two pounds of bees-wax and four pounds of resin; stir well together, and keep in a cool place in the dish in which it was melted. If bees-wax is a very costly item, one-third less quantity can be used.

THE FLOWER GARDEN.

GUNNERA SCABRA.

THIS vigorous and noble plant Mr. Darwin met with in a region where the vegetation is so luxuriant that the branches of the trees extend over the sea, somewhat like those of a shrubbery of evergreens over a gravel walk.

"I one day noticed," he says, "growing on the sandstone cliffs some very fine plants of the Panke (*Gunnera scabra*), which somewhat resembles rhubarb on a gigantic scale. The inhabitants eat the stalks, which are sub-acid, tan leather with the roots, and prepare a black dye from them. The leaf is nearly circular, but deeply indented on its margin. I measured one which was nearly eight feet in diameter, and therefore no less than twenty-four feet in circumference! The stalk is rather more than a yard high, and each plant sends out four or five of these enormous leaves, presenting altogether a very noble appearance." Of a spot in the same neighbourhood he says:—"The forest was so impenetrable that one who has not beheld it cannot imagine so entangled a mass of dying and dead trunks. I am sure that often for more than ten minutes together our feet never touched the ground, and we were frequently ten or fifteen feet above it; so that the seamen, as a joke, called out the soundings!" Mr. Darwin does not speak of the inflorescence, which is more remarkable than the leaves. The little flowers and seeds are seated densely on conical fleshy masses a few inches long, and these in their turn being seated as densely as they can be packed on a thick

Gunnera scabra. (From a sketch in Battersea Park, September 1870.)

stem, the whole has the appearance of a compound cone several feet long (on strong plants), very heavy, and perhaps the oddest-looking thing ever seen in the way of fructification. This great spike springs from the root itself, the leaves also springing from the root, as in the case of the rhubarbs. Two plants in an artificial wet peat bog near London—one in deep rich soil, with the crown well raised above the level, and the whole protected under a couple of barrowloads of leaf mould; the other left exposed, and not allowed any particularly good soil, grew very well. Both plants survived the severest winters, but the protected and well-fed one grew much the larger. The leaves of the larger plant used sometimes to grow four feet in diameter, the texture being of extraordinary thickness and rugosity. In the Royal Gardens at Kew it grows to a larger size than that. The bottom there is the reverse of bog, while the situation is warm and sheltered. The Kew people met its wants by building a little bank of turf around it, so as to admit of its getting a thorough dose of water now and then, while in winter it was protected with dry leaves and a piece of tarpaulin. Similar protection, plenty of water in summer, and a warm and sheltered position, are all that are necessary for success with this very striking subject. It is not difficult to obtain, and may be easily raised from seed, though that is a slow way. It should be planted in some isolated spot, and not, as a rule, in the "flower-garden proper," as it must not be disturbed after being well planted, and would associate badly with the ordinary occupants of the parterre.

In places with any diversity of surface it will be easy to select a spot well open to the sun and yet sheltered by surrounding objects.

The plant, of which our woodcut is an illustration, was growing in a damp, somewhat hollow bed along with several moisture-loving plants, and here it had stood several winters uncovered and without injury,

THE POLYANTHUS.

BY JOHN WIGGINS, ISLEWORTH.

CULTIVATORS of this charming spring flower are now of opinion that it is essentially better to have their Polyanthus strong in habit and constitution, and bearing large trusses well laden with showy flowers, of large size and distinct in colour, than to insist on that perfection of form, without which florists used to consider them worthless. In a true florist's flower the pips should be large, quite flat, and circular, with the exception of the small indentures between each division of the limb; the eye should be perfectly round, and of a bright yellow, quite distinct from that of the ground colour, and the tube well filled with the thrum or anthers; for needle-eyes are considered a great defect. The ground colour should be of a dark rich brown, or crimson, resembling velvet, or it may vary from black to a bright scarlet, but in every case it must be pure, distinct, and constant. The edging should resemble bright golden lace, clear, distinct, and unmixed with the ground colour along the inner margin; and so closely ought it to resemble the colour of the eye as scarcely to be distinguishable from it. The trusses should also be large, compact, and well furnished with bloom. Although all these qualities are thought to be necessary in a really good florist's flower, it is found that such flowers not only often produce inferior flower spikes as regards quantity of individual blooms, but that the blooms themselves are frequently much smaller than some of the pin-eyed kinds. For spring garden purposes, therefore, I select kinds having a good habit and plenty of flowers, and, above all, bright, large, and showy blooms. As regards habit, size, and quantity of bloom—we have obtained all that can be desired; but in the way of new and improved colours little has of late been effected. This season I had plants with trusses carrying from sixteen to twenty-four blooms, each of which was larger than a two-shilling piece.

PROPAGATION.

Common garden varieties are usually raised from seed, which germinates more freely than that of most plants. It may be sown at any time after it is ripe; some sow in the autumn, some in spring, and others immediately after the seed is gathered. For my part I prefer sowing late in April or early in May, in shallow pans or wooden boxes, which are placed in cold frames, and kept a little shaded and close for a time. The seeds quickly germinate, and as soon as the young plants make two rough leaves, I prick them off singly into thumb pots, or six or eight into a four-inch pot, which will be sufficient for them until midsummer. I then prepare beds for them by deeply working the soil, and adding to it some well-decayed manure. Into these beds the seedlings, when large enough, are planted in lines a foot or fifteen inches apart. The finer, or named varieties are increased by division of the crowns after they have done blooming, and are either inserted at once in beds or borders, or, as is more generally the case with named varieties, they are reotted.

SOIL.

Polyanthuses grow vigorously in almost any garden soil, more particularly if it is rich and a little moist. Where trouble is taken to form a compost especially for them, I should recommend a strong fresh loam, enriched with well decomposed leaf mould, and rendered porous by means of a liberal admixture of sharp sand. Thoroughly decomposed cow or stable manure may also be advantageously employed; but to such manures, unless really necessary, I have a great aversion; for not only do they harbour grubs and other insects, but they also encourage a luxuriance that proves detrimental to the quality and quantity of the flowers. I have frequently produced beds of polyanthus of great excellence without the assistance of

any manure, relying simply for success on deeply worked thoroughly pulverised soil.

SITUATION.

As the *Polyanthus* is somewhat impatient of heat and drought, a cool, partially shaded and sheltered situation suits it best. If, however, the plants are copiously supplied with water throughout the dry season, they will stand a good deal of exposure to the sun. Where their requirements can be fully attended to, perhaps the best aspect for them would be a north-west one. The finer kinds mix well with alpiners; the others look well in front of shrubberies, where they should be arranged in clumps. Such as are still interested in the true florist's kinds should grow them in pots. When in bloom remove them to some shady nook, such as between two rows of hedges—in fact, anywhere where they can be kept cool, shaded, and protected from bright sun, wind, and heavy rains.

THE DAHLIA AS A DECORATIVE GARDEN PLANT.

THE Dahlia is so constantly before the public at exhibitions in a cut state, that its usefulness for the decoration of the flower garden is in some danger of being underrated. For planting in shrubby borders, however, or for filling large beds in grass plots, there is nothing more attractive when massed with a due regard to harmony of colours and heights. Take a shrubby border, for example, with ample width for planting, and imagine the effect that would be produced by a background of hollyhocks, then a line of Dahlias, another of *Salvia patens*, and then a line of *Pentstemons*, edged with *Tom Thumb Antirrhinums*. A large circular bed, with a few hollyhocks in the centre, then a broad band of Dahlias, with *Antirrhinums*, *Pentstemons*, and *Phloxes* in the front, would also have a charming effect. Where lines cannot be arranged in shrubby borders, Dahlias might be planted singly; and there are many other ways in which, with a little taste and judgment, they might be employed. I look back with regret on the beds of Dahlias I used to see twenty years ago, now displaced by many plants much less ornamental. The Dahlia, I need scarcely say, possesses rich, striking and effective hues of colour. From pure white to nearly black, from the delicate tinge of soft primrose to rich golden yellow, there are included manifold hues and combinations of colours, allowing of an almost unlimited choice. The four groups into which Dahlias are divided—viz., show, fancy, bedding, and pompones—all yield excellent varieties. A selection from the two former groups is absolutely necessary, in order to get those that produce flowers somewhat erect and striking, and not, as is common with some, hanging downwards, leaving only the backs of the flowers exposed to view. Among show flowers, such a habit of growth as *Fellowes's Queen of Beauties*, and among fancies such as *Legge's Glory*, are just the types to obtain. There is no uniformity as to the height to which the Dahlia will grow, so there is plenty of choice when forming a mass; the average height may be set at from 3½ feet to 5 feet. The proper average height for bedding Dahlias should be from 2 feet to 2½ feet; they should have a rigid, compact growth, and be very free-flowering. Some should bloom early, others later—all points to be remembered. If they lack the fine form and fullness of the show varieties, the deficiency is more than compensated for by the masses of flowers they produce at the height of the blooming season. The following varieties can be confidently recommended: *Alba floribunda nana*, pure white; *Anora*, yellow tipped with lake; *Bob Ridley*, red; *Cloth of Gold*, bright yellow; *Crimson Gem*, rich crimson; *Prince Arthur*, crimson; *Rising Sun*, intense scarlet; *Royal Purple*, purple; and *White Bedder*. There are a few edged flowers, but as a rule they are not so free-blooming nor so continuous in bloom as the self-coloured flowers. The *Pompones*, *Bouquet*, or *Lilliput Dahlias* have small, compact, and interesting flowers, and are extremely useful for cutting for bouquets. Many of the flowers are models of form, and are likewise very pretty. Their usefulness for decorative purposes in the flower garden is somewhat marred by the fact that generally the pompones Dahlias are tall in growth, and have a loose habit. Some few of them have, however, dwarf, close habits, and are beginning to be much used for bedding purposes. In planting Dahlias in ribbon lines or small beds, or as an edging to larger beds, it is often essential to keep them dwarf, and that with as little trouble as possible. Stakes are apt to show themselves, and have an unseemly appearance, and it is well to avoid their use as much as possible. They are indispensable to the taller-growing kinds; but in the case of the dwarf varieties it is the practice of some growers, as soon as the plants are large enough to require security from breakage by wind, to carefully remove the earth from one side of the plant, and gradually press down the main shoot, without breaking it, towards the earth. It is then secured by means of two small stout sticks placed crosswise, and as soon as the side

branches are large enough to be in danger from wind, they are pinched near the main stalk sufficiently sharp to make them fall towards the earth. This injury, however, is only temporary, as they soon recover themselves and begin to grow upwards, and bloom most effectively. This operation is performed more than once if necessary, until the plants fill out and meet, and so help to sustain each other against the action of the wind; at the same time the soil is quite covered, and only green leaves and masses of striking flowers are seen.—*Quo.*

Foxgloves.—Among the many hardy flowers in bloom during the present month, none exceed in gracefulness and beauty of colour the common foxglove—"a third part bud, a third part blossom, a third part past, a type of the life of this world," as the author of "The Stones of Venice" has it. The white and common kinds are not flowers that suggest the desirability of improvement, but even these have been improved from the florist's point of view, and there is now in some gardens a strain with the flowers variously and prettily marked and spotted. These particularly are well worthy of culture, and in no way more attractive than with their great spikes standing amidst low shrubs and covert in wild places or in woods, copses, or rough shrubberies. All that is necessary to establish them in such places is to take a little of the seed in the pocket, and when walking about scatter it here and there in spots where it has a chance of vegetating. This should be done as soon as the seed is ripe, and not deferred till spring, as thereby nearly a year would be lost.

Saving Seed of Roses.—The rose shears will soon be in constant operation, cutting off every faded flower. May I ask that the hand may be stayed when about to snip off those which are likely to produce seed? The endless variations of colour and shape of the flowers, the manner which those seedlings reproduce the traits of the parent, at one time the leaf, at another time the flower, will induce an interest in the work which will amply repay the annoyance of seeing a few seed-pods scattered about among the flowers throughout the summer. The seedlings will not, I promise, produce all double flowers—but even a briar, with blossoms as large again as those of the dog-rose, and having a colour equal to that of *Count Cavour*, would not, I imagine, be despised; then there would be yellow briars and briars of every shade of colour. But they do not all come briars, even if the seeds are taken from roses worked on that stock; a good proportion come roses, passable roses, with an increased vigour, although deficient of the quality to bring them up to the standard of the parent as to form. The colour will be found somewhat after that of the parent, although yellow kinds often produce seedlings that bear pink blooms, with leaves like those of the parent; but the blooms are larger and of a deeper colour than those of the common briar. Those who do this find they have plenty of stocks to work favourite varieties upon; besides the pleasure of having one's own seedlings, and a chance of raising, now and then, something good.—*HENRY MILLS, Enys, Cornwall.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Lilium giganteum.—In a warm nook between two hedges in Mr. Ware's nursery, at Tottenham, this noble lily is now beautifully in bloom. It has stood in the same position quite unprotected for these last two years.

Carnation Blooms.—In order to preserve the blooms of pinks, picotees, and carnations for exhibition purposes, a fine plump bud just on the point of opening is selected, and drawn through an inverted six-inch pot so as to leave the bud resting above the hole. In order to ward off heavy rains and strong sunshine, another smaller pot is inverted over the bud so as to keep all secure. In this way the blooming period is considerably lengthened, and the quality of the blooms preserved.—*W. F.*

Verdant Wigwams, &c.—In the Royal Botanic Gardens at Dublin, there is a singular wigwam made by placing a number of dead branches so as to form a framework, and then planting *Aristolochia Siphon* all round these. It runs over them, and the large leaves make a perfect summer roof. I write to suggest that this be done in various other cases with some of our fine-flowering climbers. These would often look better on such structures than if tortured on walls or trellises. We should have beautiful masses of bloom outside, and grateful shade within. The autumn-blooming *Clematis Flammula* is also capitally suited for this purpose.—*Bowen.*

Bare Beds in Hyde Park.—I see that in No. 32, you very properly direct attention to the state of the beds near Albert Gate, Hyde Park. It must be confessed that it is a complete waste of time and money to plant tender plants out of doors for such a short time as now remains of what may be termed "the season" for tender outdoor-plant display. May I be allowed to ask why the beds are kept thus long without their summer occupants? Several so-called sub-tropical plants, notably some of the *Cannas*, stood out last winter in the plantation near the Serpentine Bridge in Kensington Gardens, and are now growing strongly. Indeed, *Cannas* generally would have been much the better for being planted out earlier. I remember when Mr. Bullen had the management of the bedding-out in Hyde Park, that he commenced to "bed out" early in May, and nearly all the "tropicals" were out by the first week in June. Thus treated, by this time they would make attractive ornaments, whereas if put out now, by the time they get well established it will be time to take them in again.—*T. SPANSWICK, Hammermith.*

THE HOUSEHOLD.

A CHAT RESPECTING SALADS.

(From Blackwood's Magazine.)

"I WONDER," said MacTavish, as the materials for the salad were placed upon the table, "whether anyone has ever written a book upon salads?"

"Not to my knowledge. Even Brillat Savarin, the only man who has written tolerably well upon the philosophy of dining, has not thought proper to devote a chapter to the subject, though it might well have tempted him. I think if any enterprising publisher would give you and me, say a thousand guineas for the job, we could get up a nice little volume, in which we would discuss it historically, gastronomically, philosophically, poetically, medicinally, and anecdotically—make it, in fact, the text-book of the subject, now and for evermore."

"I never wrote a book in my life, and don't intend," replied MacTavish; "but I would read such a book if it were published, and if it were the work of a gentleman, a scholar, and a man of the world."

"Rare combination! Supposing I now—excuse the modesty—were to write the book, how should I begin? *Firstly*, I should look into the etymology of salad, and should find that the word was derived from *sal*, salt, and that therefore it means something salted, or *salada*, as they say in Spanish and Italian. This would afford an opportunity, *in limine*, for diverging into an historical chapter or two upon salt, beginning with the creation of the world and the salt sea, and why the sea is salt, and could not be fresh with safety to the denizens of the dry land. If I did not go into the geology of the subject, and descend into the salt-mines, or explore the salt-licks of which the buffaloes are so fond, I could at all events begin with Lot's wife, and end with the revenue of £5,300,000 per annum, which Lord Cranbourne informed the House of Commons and the country was paid by the poor people of India as a tax upon the sea-salt, almost the only condiment which they use with their wretched dinners of boiled rice. . . . Too much salt in the book, or the salad, would be equally misplaced; and I should be compelled to reserve a little space for vinegar, its history, traditions, and uses; for olive oil, that choice blessing of all-bounteous heaven, with which kings were formerly anointed, and without which a true and wholesome salad would be impossible; for pepper, for mustard, for sugar, and for hard-boiled eggs."

"For sugar?" inquired MacTavish, dubiously.

"Yes sir, for sugar," I replied, emphatically, with a look that would have suited Johnson when snubbing Boswell. "Without a judicious, a slight, but a palpable flavour of sugar, a salad, however scientifically prepared in other respects, must be deposited from the first to the second rank, and belong to the insipid mediocrity which, in salads as in poetry, is detestable to gods and men. The sugar is necessary to harmonise all the other ingredients, so that the complete work should be without a flaw, a defect, or a note of discord; and as perfect in its way as a poem, a picture, a statue, a tune, a cathedral, a stained-glass window, or any other work of art."

"Does Shakespeare, who does not mention tobacco—the more's the pity!—make any mention of salad?"

"He does, five or six times. In 'Henry VI.,' Jack Cade, in his extremity of peril when hiding from his pursuers in Iden's garden, says that he has climbed over the wall to see if he could eat grass or pick a salad, 'which is not amiss,' he adds, 'to cool a man's stomach in the hot weather.' In 'Anthony and Cleopatra,' the passionate Queen speaks of her 'salad days, when she was green in judgment, cool in blood.' Here the word means raw and unripe, but a proper salad well-prepared is neither. Hamlet uses the word with the more ancient orthography of 'sallet,' and says in his speech to the players, 'I remember, one said, there were no *sallets* in the lines to make them savoury.' By this he meant that there was nothing piquant in them—no Attic salt. Now, the salad which we are about to mix shall be fresh and cool as in Cleopatra's allusion, and piquant as in Hamlet's. A salad is no salad if it do not partake of both qualities."

"I wonder," said Mr. MacTavish, "what the cookery-books say upon the subject; though, to the best of my knowledge and belief, there has never been written or published a good cookery-book fit for the reading of any one better than the habitual denizens, male or female, of the kitchen. Waiter! fetch Mrs. Rindell's cookery-book from the library."

The book was brought, and MacTavish read aloud, "How to make a French salad.—Chop three anchovies, a shallot, and some parsley small; put them into a bowl with two tablespoonfuls of vinegar, one of oil, a little mustard and salt. When well mixed add by degrees some cold roast or boiled meat in very thin slices; put in

a few at a time, not exceeding two or three inches long. Shake them in the seasoning and then put more; but cover the bowl close, and let the salad be prepared three hours before it is to be eaten. Garnish with parsley and a few slices of the fat."

"Make your salad three hours before you consume it!" said I. "Three minutes, or *one* minute, will suffice. Mrs. Rindell was a fool—her recipe for what she calls a French salad is execrable. How does she make what I should call an English salad?"

"She has not a word to say on the subject—nothing but the following, which she calls a lobster salad:—

"Make a salad, and put some of the red part of the lobster to it, cut. This forms a pretty contrast to the white and green of the vegetables. Do not put much oil, as shell-fish absorb the sharpness of the vinegar. Serve in a dish, not a bowl."

"Mrs. Rindell knew nothing of the subject. Anchovy and slices of meat and 'fat' are no fit ingredients of a salad, either French or English. And then the crass stupidity of her recommendation of two spoonfuls of vinegar to one of oil! The woman was ignorant of the merest A B C of her art, and knew as much about a salad as Nebuchadnezzar when he cropped the herbage, or as any donkey who browses upon thistles with no other condiment than his hunger. Let us hear what Fracatelli says."

Fracatelli's book was sent for, but afforded no information except about a Russian salad with lobsters, a German salad with herrings, and an Italian salad with potatoes—none of them the true, fresh, seasonable summer salad which Frenchmen make so well, and which Englishmen can equal, if not surpass, if they will take the trouble.

"Never mind the stupid cookery-books," said MacTavish; "let us talk."

"Of all the vegetables of which a salad can be made, a lettuce is unquestionably the best. Have the kindness, Mr. MacTavish, to assure yourself that these lettuce-leaves are quite dry. There must be no drops of water left upon the leaves to mingle with and weaken the vinegar or object to coalesce with the oil. 'The lettuce, when it is *panachée*,' says the 'Almanach des Gourmands'—that is, when it has streaked or variegated leaves, and is not all green like a cabbage—is truly a salad of distinction'—*une salade de distinction*. None but a Frenchman could pay such a compliment. The milky juices of the lettuce are similar in their soporific effects, though in a minor degree, to those of the poppy, and like opium predispose the mind of him who partakes wisely but not too well, to repose of temper and philosophic thought. There should always be a flavour of onion—spring onions are best—in a salad, if as the Frenchman says, it is to be one 'of distinction.'"

"Here they are," said MacTavish, "young, fresh, and tender, and about the eighth of an inch in diameter."

"The right size. Chop them up fine. Next to the lettuce comes the cucumber as the best material for a salad. Dr. Johnson, or some other burly big-wig of criticism, declared that the best thing you could do with a cucumber, after you had prepared it with much care and thought, and with all the proper ingredients, was to throw it out of the window. But the great lexicographer was a man of strong prejudices, or he would not have gone out of his way to libel Scotland—a great country, sir—and the Scotch a noble people, who have made their mark in the world, sir. Neither did he know everything, or he would not have traced the etymology of 'cucumber'—he was one himself—to *cœur méchant*, for his heart, notwithstanding his infirmities of temper, was essentially kind. He was a gross eater, a glutton—a *gourmand*, not a *gourmet*: and there is as wide a distinction between the two as between a wolf and a lap-dog. It is my conviction, in spite of Dr. Johnson—even had he been a Doctor of Medicine or of Divinity, and not a mere Doctor of Laws, a title which signifies nothing, but that the man who bears it is an honorary magnate of the republic of letters—that a cucumber, cut in the thinnest possible slices, and with the proper seasoning of vinegar, oil, salt, pepper (and no sugar), and either with or without an accompaniment of spring onions, or the French *ciboule*, is a diet as wholesome as it is savoury and refreshing. The moot point as regards cucumber is, whether it should be sliced with or without the rind. My excellent friend and physician from the Shetland Isles, the author of the 'Cyclopædia of Medicine,' a better authority than Dr. Johnson, maintains that the rind of the cucumber is the best part of it, as that of the lemon is, for flavour and aroma, and that, moreover, it very materially aids the digestibility of this particular form of salad. For my part, I am content to sit at his feet a disciple, and accept his dictum as a dogma. Third in my list of salads is *endive*, that comes to us in the winter, when we have no other such green and pleasant visitor. And after *endive*, recommend me to celery, without admixture of any other vegetable, as the basis of what the 'Almanach des Gourmands' calls a *salade très distinguée*. The only peculiarity about it is, that you should double

or treble the quantity of mustard which you would use for lettuce or endive. Though not strictly a salad, there is a mixture, very common in early summer in Italy, which deserves honourable mention—boiled *asparagus*, allowed to grow cold. With the usual dressing it is far preferable in this way to the hot asparagus and melted butter which is the usual dish in this benighted country, where, as Voltaire says, there used to be '*cinquante religions et une seule sauce!*'"

"All these salads are good," interposed MacTavish, "but I think, lettuce excepted, there is one other that transcends them all. Were you ever in America?"

"Yes, for my sins."

"And I," said MacTavish, "for my merits and the increase of my experience. Having been there, either for your sins or your virtues, you must have dined at the New York Hotel or at Delmonico's; and if it were in the summer-time, with the heat at 104° in the shade, as it has been during this fiery July, as I learn by a letter I have just received, you must have partaken of a tomato salad."

"I was coming to the tomato," I replied. "It is a noble fruit, as sweet in smell as the odours of Araby, and makes an excellent, and, were I a Frenchman, I would say, an illustrious salad. Its medicinal virtue is as great as its gastronomical goodness. It is the friend of the hale to keep them hale, and the friend of the sick to bring them back into the lost sheepfolds of Hygeia. The Englishman's travelling companion, the blue pill, would never be needed if he would pay proper court to the tomato—not as we consume it in England, as a sauce, but as a cooked vegetable, stewed, or, better than all, as a salad. Would that, in our cold climate, it could be grown to perfection!"

"Amen to that sweet prayer!"

"I have now mentioned, I think, all the main ingredients of the true, fresh, summer salads. The minor ingredients are water-cress, which is not to be highly recommended; the common mustard and cress, which are good if used sparingly; and the beetroot. The latter, after being boiled and allowed to cool, may be cut into thin slices and advantageously compounded with the lettuce and the endive, but should never be used with the cucumber or the tomato. It spoils the colour of the one, and is an unnecessary surplussage to the colour of the other. The true lover of salad need not be deprived of his favourite food at any period of the year; for when the fresh green vegetables fail, there are always potatoes, onions, and beetroot to fall back upon. The Russians and the Germans make a very excellent salad of cold potatoes, cut into slices about an eighth of an inch thick, with thinner slices of fresh onions and beetroot, and a sprinkling of parsley chopped very fine.

"In addition to these, which may be called the legitimate salads or salads pure and simple, compounded solely of vegetables, are lobster salads, ham salads, chicken salads, and mixtures, such as the Dutch and Germans make with sausages, herrings, anchovies, and sardines. All such messes ought to be called mayonnaises, and not salads. They are only fit for *gourmands* and not for *gourmets*; and those, more especially, which are mixed with fish of any kind are an abomination.

"And having discoursed so far, let us proceed to the business immediately before us—our own dinner and salad. You will do the work, Mr. MacTavish, while I do the talking. Place the egg in the bowl and carefully remove the white. It must have been boiled ten minutes at least, or it will not answer its purpose, which is simply to add a little consistency to the mixture which we are about to make. Half-a-dozen broad Windsor beans, well boiled, with the skins removed, would answer the purpose still better if beaten into a *purée*; but for to-day, as there are no beans, the egg must suffice. The next time we make a salad the broad beans shall be provided, and no animal ingredient of any kind shall interfere with the purely vegetable character of the dainty. Now add a teaspoonful of salt and three teaspoonfuls of mustard. I hope the mustard is genuine, and not adulterated trash—ten per cent. of mustard and ninety per cent. of flour coloured with turmeric, which is sold by the rascal grocers of this swindling metropolis, for whose special behoof it were to be wished the pillory and the whipping-post could be revived. To be quite sure of the requisite pungency, add a little cayenne pepper, and pound the mixture well together at the bottom of the bowl with a silver spoon. Next add a spoonful of vinegar, and discard the silver for an ivory or hardwood spoon. Here it is to your hand. Common vinegar, if pure, will answer the purpose; but for the perfect salad, tarragon vinegar, odoriferous as a garden of herbs, is a *sine quâ non*. Stir all these gently together for one minute; next add two spoonfuls, not stinted, but brimming over, of the best olive oil of Lucca. [It is worthy of note that the capital cook who writes in the *Queen*, under the signature of "The G. C.," strongly advises that the oil should be applied before the vinegar.—ED. GARDEN.] 'Niggard of your vinegar, prodigal of oil,' is an old maxim

that every salad-maker should act upon. Stir again for a minute or two, till the ingredients are well mingled; and then, as the finishing touch, add half a teaspoonful of brown sugar; once again ply the spoon for a minute, when the mixture will be ready to receive half-a-dozen little spring onions cut fine, three or four slices of beetroot, the white of the egg cut too small, and the lettuce itself—to the beauty of which all the rest are but the adornments. The lettuce, crisp and dry, is the king, of whom the other ingredients are but the ministers and the courtiers. Have a care to remove the hard stock, and use only the tender leaves, with the brittle spinal columns that support them. Do not shake the mixture too violently or too long. It used to be said, *Fatiguez la salade*, but this is error. It is sufficient that every portion of the vegetable should come in contact with the mixture; and a very gentle stirring, so as not to break or bruise the lettuce, is all that is required."

Mr. MacTavish was as docile as a disciple should be, and the salad thus compounded was pronounced to be a success, not merely of that modified kind which in dramatic criticism is delicately called a *succès d'estime*, but such a decided success as at the theatre brings down the bouquets at the feet of a *prima donna*.

Orange Mince.—Peel sweet Havana oranges; remove seeds; slice, and then cut slices into small pieces with very sharp knife. Add finely chopped lemon without peel in the proportion of half a lemon to six oranges; also a finely grated cocoa-nut if desired. Make a thick syrup by dissolving and boiling for ten minutes a pound of sugar in a pint of water; pour this hot syrup upon the fruit. Set it aside to cool. Serve in a glass dish.

Boiled Lettuce.—This, to our taste, is a delicious vegetable, and the *gout* is something indescribable, resembling asparagus or sea-kale, and yet not quite like either. Lettuces may be simply boiled and eaten as other greens, but they can be boiled and served as *entre-mets* in a variety of ways. Have ready some neatly-cut pieces of toast, a pale brown colour; lay them on a dish, a *hot one*; let each piece be of a size to hold the lettuce and one poached egg; pour over the toast a little of the water and some good gravy; if the latter be not handy, a little fresh butter should be spread on the toast previous to pouring the water from the lettuce; place on each piece of toast enough of the boiled lettuce to form a flat layer; neatly trim the edges of the vegetable, and place a poached egg on the top; or, prepare some toast as above, and spread over each piece a thin layer of anchovy or bloater paste, on which lay the lettuce; then season to taste. To prepare the lettuces for boiling they should be well cleansed, and the top of the leaves, if they have the slightest appearance of fading, cut off; leave as much of the stalk as possible, cutting off the strong outer skin. The stalk is, when boiled, the most delicious part. The large cos lettuce makes the handsomest dish, but we prefer the flavour of the drumhead.—*Knife and Fork.*—[The fine Batavian endive, so well-grown about Paris, is not uncommonly used as a boiled vegetable, and in a much more simple way than that above described. It makes a very palatable dish.]

NOTES AND QUESTIONS ON THE HOUSEHOLD.

Martynias.—These make one of the finest pickles we have, and if once tried will always be grown. Sow when the ground is warm; and when large enough, transplant into rows, two feet apart, allowing eighteen inches between the plants.—*Agriculturist.*

Green Shelled Peas for Winter Use.—Will any of your readers kindly inform me as to the best way of preserving green shelled peas for winter use? Can they be preserved in the same way as French Beans?—i. e., by a layer of salt and a layer of beans?—W. P.

Cauliflower Salad.—Boil a cauliflower in salted water till tender, but not overdone; when cold, cut it up neatly in small sprigs. Beat up together three tablespoonfuls of oil and one tablespoonful of tarragon vinegar, with pepper and salt to taste; rub the dish very slightly with garlic, arrange the pieces of cauliflower on it, strew over them some capers, a little tarragon, chervil, and parsley, all finely minced, and the least bit of dried thyme and marjoram, powdered. Pour the oil and vinegar over, and serve.

How to Preserve Vegetable Marrows.—Peel the marrows, take away the seeds, cut the vegetable into small pieces. To every pound of marrow add half a pound of sifted loaf sugar, the rind and juice of a lemon, half an ounce of grated ginger. Put these into a basin and let them stand all night. The next day pour the juice into a pan and let it boil up, then add the vegetable. Boil all together an hour and a half, or until it becomes thick and transparent. If put into a mould which will not affect the acid, the preserve will look very nice when turned out for use. Most vegetables may be prepared in the same way.

Tea.—Tea, in anything beyond moderate quantities, is as distinctly a narcotic poison as is opium or alcohol. It is capable of ruining the digestion, of enfeebling and disordering the heart's action, and of generally shattering the nerves. And it must be remembered that not merely is it a question of narcotic excess, but the enormous quantity of hot water which tea-bibbers necessarily take is exceedingly prejudicial both to digestion and nutrition. In short, without pretending to place this kind of evil on a level, as to general effect, with those caused by alcoholic drinks, one may well insist that our teetotal reformers have overlooked, and even to no small extent encouraged, a form of animal indulgence which is as distinctly sensual, extravagant, and pernicious as any beer-swilling or gin-drinking in the world.—*Lancet.*

GARDEN DESTROYERS.

BARK-BORING INSECTS.

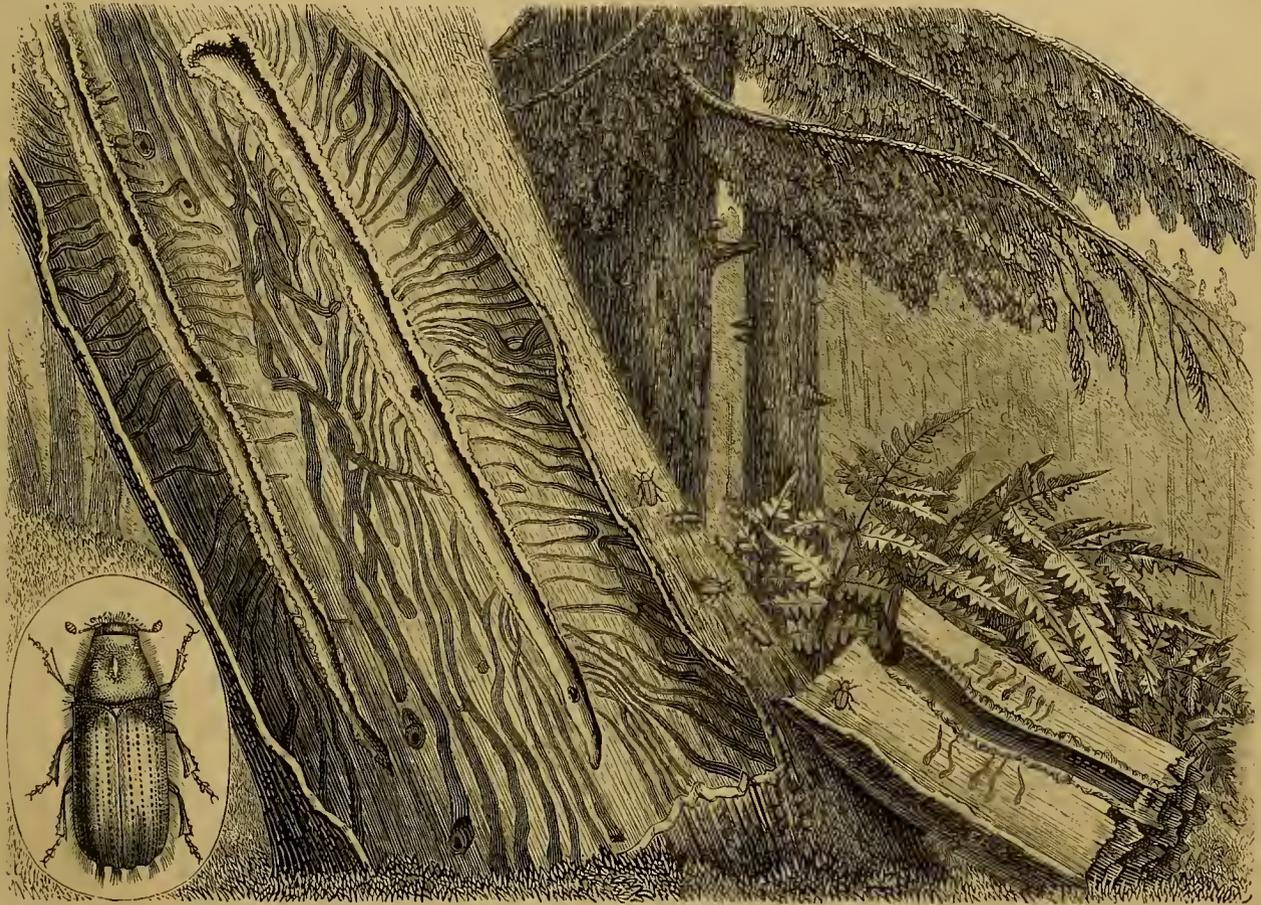

(HYLURGUS PINIPERDA.)

(Continued from Vol. I., p. 629.)

IN our previous paper on bark-boring insects, we drew attention to the different arrangements of the borings made by different species as one of the means of recognising the insect that made them, but we gave no figure of these. We now, however, give one, which will at the same time illustrate that class of borings where the mother gallery is longitudinal in the same direction as the growth of the tree, and will also show the borings of the female parent of the Pine-borer (*Hylurgus piniperda*), of which we gave an account at p. 518. The enlarged figure of the insect in the corner is a very good and characteristic portrait of *Hylurgus piniperda*; and the borings show

country and on the Continent, for the destruction of the mildew and blight attacking vines, hops, roses, fruit, and other trees; and it is now, I believe, almost the sole remedy employed for that purpose, as no other has been found so generally effectual or so convenient of application.

From often-repeated experiments, I have arrived at the conclusion that the beneficial action of sulphur is to be attributed to the presence of a small but variable quantity of free sulphurous acid (occasionally hyposulphurous acid), which exists as a constant impurity in the sulphur of commerce. Sublimed sulphur contains more acid than powdered crude sulphur, and is more certain in its action, while precipitated sulphur, being almost, or altogether, free from acid, is quite useless. I find that when substances are carefully purified from all traces of sulphurous acid by repeated washing with spirit and water, they are equally ineffectual in destroying mildew and other vegetable and animal organisms; that seeds germinate as quickly and vigorously when sown in pure sulphur as in fine sand, and that moulds grow on

The Pine-boring Beetle (*Hylurgus piniperda*) and its Galleries

the large central gallery made by the mother insect, and the smaller borings, made by the larvæ, branching off from it at the point where each egg had been laid and increasing in size as the grub grows bigger. A. M.

SULPHOZONE, A SUBSTITUTE FOR SULPHUR.

READ BY CHARLES ROBERTS, F.R.C.S., AT THE BIRMINGHAM HORTICULTURAL CONGRESS.

SULPHUR in the sublimed, precipitated, or powdered form, is extensively employed by horticulturists, for destroying mildew. The substance to which I have given the name of sulphozone (from its strong smell and powerful chemical action), in order to distinguish it from the sulphur of commerce, is a preparation containing free sulphurous acid as its active and essential principle. For many years past large quantities of sublimed and powdered sulphur have been used in this

the surface when a little organic matter, as flour, has been mixed with the sulphur. I find also that cheese mites are not destroyed by pure sulphur, but live and multiply indefinitely in cheese covered with sulphur; though they are immediately destroyed by commercial sublimed sulphur. On the other hand, when pure sulphur is impregnated with sulphurous acid, it destroys mildew and other minute organisms with an energy proportioned to the quantity of acid it contains; and it does not appear that one form of sulphur possesses any advantages over the others, provided the quantity of acid is uniform. Many other substances which contain no sulphur, when impregnated with sulphurous acid in a similar manner, and to the same extent, are equally effectual in destroying mildew.

In addition to its destructive action on organized bodies, sulphurous acid possesses a powerful chemical action on the organic and inorganic products of decomposing animal and vegetable substances, and the emanations from persons and animals suffering from infectious diseases; hence it is one of the most potent and valuable disinfectants

we possess. It attacks and destroys sulphuretted hydrogen, and neutralises the strong smell of ammonia and other alkaline bases, but without losing its antiseptic properties, or destroying their manurial value. From my experiments and observations, and from well-known properties of sulphurous acid, I may repeat that it is the acid, accidentally present in the sulphur, which is the active agent in the destruction of mildews and blights, and that the sulphur is only the medium for its application. This is a fact, not only of scientific interest, but of great practical and commercial importance; for under the mistaken impression that the sulphur itself is the active agent, great care and expense have been incurred to secure its freedom from acidity, which is by no means necessary. For horticultural purposes, however, it is necessary to limit the quantity of sulphurous acid, or it would prove destructive to the plant as well as to the parasite. This limit I have established practically by experiments made on rose trees infested with mildew; and as the rose mildew is with difficulty destroyed by common sulphur, except by repeated applications, this preparation (to which I have given the name of sulphozone, for reasons already given) may be considered to be of the maximum strength, and four or five times stronger and more potent than sublimed sulphur. In substituting it therefore for sulphur, a great saving will be effected in the cost of sulphur, its carriage, and the time and labour of applying it. There will, moreover, be the additional advantage of not loading the foliage with a large quantity of sulphur powder, which must in some measure impair health by its mere mechanical presence. Sulphozone, being a fine dry powder like sulphur, may be applied in a similar manner, and with the same apparatus, care being taken to use a much smaller quantity (*i.e.*, about a quarter of that of sulphur).

For sanitary purposes a very strong sulphozone has been prepared. This is exceedingly destructive to organic life, and is not adapted for horticultural purposes, except for dressing the stems and branches of deciduous trees in winter, and for destroying insects where it can exert no deleterious influence on surrounding vegetation, or for deodorising manure-heaps, &c., for which purpose it is better adapted than any other disinfecting powder, as the sulphurous acid fixes the ammonia—the most valuable constituent of manure—and makes it available for gardening and farming purposes, while chlorine and other disinfectants destroy it, and reduce the value of the manure in proportion to the extent of their action in deodorising it.

Radishes a Decoy for the American Brown Grub.—

In some parts of the United States the brown grub has this season proved very injurious to melons and cucumbers, cutting them down by dozens. The ordinary remedies, such as charcoal, coal ashes, &c., have entirely failed; but the introduction of radishes about the plants has been of great service, as the insects congregated around them; the radishes are frequently examined, and the grubs are destroyed.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Mole Crickets.—I send herewith an insect which is a great pest in gardens in this locality, especially low-lying wet land; our gardeners call it an earth cricket. It commits great ravages amongst early potatoes. Will you kindly advise us how best to destroy it?—C. R. ROBINSON, *Teignmouth*.—[Your pest is the Mole Cricket, figured and fully described at p. 97, vol. i., of THE GARDEN. We should be glad of a few fresh specimens.]

Coal-tar a Remedy for Caterpillars.—A terrible insect is the wood-gnawing caterpillar (*Cossus*). It gets under the bark and into the wood of Elms, Willows, and Poplars, and destroys them rapidly. In some valleys where Poplar trees are cultivated to a great extent, it is a positive scourge. There is, however, a simple way of preventing the mischief; it consists in daubing the base of the young trees every two years with coal-tar. A ring of this liquid painted on each tree, will have the desired effect, as the caterpillars dread it like the plague.—P. Ercan, in "Illustration Horticole."

Stinging Insects.—The following observations in a letter we have received from a correspondent in Oporto may interest our readers:—"There is one peculiarly offensive insect here, which makes a thick web round the tops of the Pine shoots, and then eats them away inside. It is a caterpillar, and is poisonous. If it falls on one's skin (it is always tumbling off the trees) it stings. It occurred to me once that it might be utilized, like Spanish flies, for blistering, and that a tincture of caterpillar might be prepared from it, and I even made some, which seemed to act perfectly. It was tried, and for aught I know is still being used, in St. Thomas's Hospital."—W. C.

The Fly-catcher and the Leaders of Young Coniferæ.—We have a young Picea 2½ feet high here, and during last summer one of those birds called "fly-catchers," took up its quarters on the leading shoots; but it also occasionally nested on the first tier of side shoots of the current year's growth. Of this I took no particular notice, except perhaps to admire its sometimes long and trying patience in watching for its prey. This spring, however, owing to the leader and some of the other branches not starting into growth with the other parts, I was led to examine them, and I found to my dismay that they were dead, and covered with the bird's excretion. Now, I would like to know if I am right in conjecturing that the latter has been the cause of their death. Be that as it may, when next I observe this bird taking up its residence on a young conifer, I shall stick up a twig for its accommodation.—J. TAYLOR, *Muesgrynne, Whillans*.

THE INDOOR GARDEN.

A REVISION OF THE GENUS DRACÆNA.

BY DR. REGEL.

(Continued from Vol. I., p. 657).

DRACÆNA THWAITESI (RGL.)

STEM simple, shrubby, covered with leaves at the top. Leaves lanceolate, lengthened-acuminate, narrowed at the base into a channeled clasping stalk, which is sometimes 2½ inches long, with a tolerably stout midrib, striated with veins, 6 or 7 inches long exclusive of the stalk (6 to 12 inches according to Thwaites), and from 1¼ to 1½ inch broad. Scales at the lower joints apparently soon deciduous. Raceme terminal, loose, simple, scarcely 2 inches long, on an erect stalk about 1 inch long, with a fascicle of bracts at the base and a few other scattered bracts. Flowers solitary or in pairs, with small scarious bracts shorter than the pedicels. Corolla 4 or 5 inches long; tube very short; divisions erect, oblong-wedge-shaped, longer than the tube. Ceylon, in shady mountainous districts. I have seen a dried specimen.

Synonym—*Dracæna elliptica*, var. *floribus minoribus* (Thwaites).

DRACÆNA OVATA (SIMS).

Leaves elliptical acute, undulated, of a lively green, folded into five prominent rib-like nerves, and striated with veins. Lower joints of the stem covered with an herbaceous scale which appears to be persistent for a long time. Raceme nest-shaped, sub-corymbose. Divisions of the corolla oblong-wedge-shaped, of a pale red colour. In other respects like *D. nigra*, A very doubtful species. Native country unknown. It is cultivated in the gardens at Berlin (according to C. Koch) under the name of *D. spatulata*.

Synonym—*Cordylina ovata* (Fl. des Serres).

ANALYTICAL KEY TO THE SPECIES.

SECTION I.—LEAVES SESSILE.

A.—Leaves with a stout midrib, which is tolerably conspicuous on both sides of the leaf.

a.—Leaves with the margin of the same colour as the rest of the leaf.

1. *D. umbraculifera*, Jacq.—Leaves from 1 inch to 1½ inch broad, and from 2 feet to 3 feet long.

2. *D. arborea*, Lk.—Leaves from 2½ inches to 3 inches broad, and from 2 feet to 3 feet long, with slight longitudinal folds.

3. *D. angustifolia*, Roxbrg.—Leaves 1 inch broad, and from 1¼ foot to 1½ foot long.

4. *D. fruticosa*, Blume.—Leaves 2 inches broad, and from 17 inches to 20 inches long.

5. *D. fragrans*, Gawl.—Leaves from 2½ inches to 3½ inches broad, and from 1¼ foot to 2 feet long, undulated.

b.—Leaves with a red margin.

6. *D. Kochiana*, Rgl.—Leaves flattish, with a very narrow red margin, from 1 inch to 1½ inch broad, and sometimes as much as 1½ foot long.

7. *D. concinna*, H. Berol.—Leaves folded longitudinally, from 2 inches to 3 inches broad, and from 2 feet to 2¾ feet long, with a well defined red margin.

8. *D. marginata*, Lam.—Leaves from ¼ inch to ¾ inch broad, and from 1 foot to 1¼ foot long, with a well defined red margin.

B.—Leaves with a midrib, which is scarcely visible on the upper surface of the leaf, but prominently convex on the underside.

a.—Leaves concealing the internodes of the stem with their clasping bases, and having the margin of the same colour as the rest of the leaf.

9. *D. ensifolia*, Wall.—Leaves of a uniform colour, 1 to 1¼ inch broad, and from ¾ to 1½ foot long. Panicle simple.

10. *D. Saposchnikowi*, Rgl.—Leaves of a uniform colour, 1¼ to 2 inches broad, and sometimes as much as 2 feet long. Panicle very branching.

11. *D. stenophylla*, C. Koch.—Leaves green and marked with yellowish longitudinal lines, from one-half to three-fifths inch broad, and from 1 to 1¼ foot long.

b.—Leaves not concealing the internodes of the stem with their half-clasping bases.

12. *D. reflexa*, Lam.—Leaves of a uniform colour.

13. *D. cernua*, Lacy.—Leaves with a red margin.

c.—Leaves concealing the internodes of the stem with their clasping bases, and having a transparent margin.

- 14.—*D. Rumphii*, Hook. Leaves from 1 to 1½ inch broad, and from 1¼ to 1¾ feet long.
 15. *D. latifolia*, Rgl.—Leaves 2½ to 3½ inches broad, and from 1¼ to 1¾ foot long.
 C.—Leaves without a midrib.
 16. *D. Draco*, L.—Stem thick, tree-like. Leaves from 1 to 1¼ inch broad, and from 1½ to 2½ feet long.
 17. *D. salicifolia*, Göpp.—Stem slender, branching, half-shrubby. Leaves two-fifths inch broad, and from 3½ to 5½ inches long.

SECTION II.—LEAVES STALKED.

- A. Leaves narrowed into a short channeled stalk, from ½ inch to 3 inches long.
 a. Flowers in a simple raceme. Rhizome throwing up several stems.
 18. *D. sureulosa*, Lindl.
 * *—Stem single, simple or slightly branching.
 a.—Bracts scarious, shorter than the pedicels, or, less frequently, longer.
 19. *D. nigra*, H. Berol.—Racemes closely crowded together, nearly sessile. Leaves with a conspicuous midrib.
 20. *D. spicata*, Roxbrg.—Racemes loosely disposed on a stalk from 3 inches to 5 inches long; tube of the corolla, thread-like.
 21. *D. Thwaitesi*, Rgl.—Racemes loosely disposed on a stalk about an inch long; tube of the corolla, funnel-shaped, and very short.
 22. *D. ovata*, Sims.—Racemes closely crowded together into a somewhat nest-shaped cluster. Leaves ribbed longitudinally, with from five to seven prominent nerves.
 b. Bracts coloured and as long as the tube of the corolla.
 23. *D. bicolor*, Hook.
 c. Flowers in a simple panicle.
 24. *D. javanica*, Knth. Leaves acute. Panicle nearly sessile, and with patent branches.
 25. *D. terniflora*, Roxbrg.—Leaves lengthened-acuminate. Panicle with ascending branches.
 26. *D. Griffithi*, Rgl.—Leaves acuminate, in partial whorls. Panicle with reflexed branches.
 B. Leaves with a channeled stalk from 4 inches to 9 inches long.
 27. *D. Aubryana*, Bronn.
 C. Leaves with a smooth stalk, channeled on the upper side.
 28. *D. phrynoides*, Hook.

The *Dracenas* have a three-celled ovary with one-seeded cells, and roots of an orange colour. The genus is distinguished from the genus *Cordylina* by the absence of stolons.

(To be continued.)

RECENT ADDITIONS TO OUR GARDENS.

READ BY MR. T. MOORE, AT THE BIRMINGHAM CONGRESS.

LET us take, said Mr. Moore, indoor plants first, and endeavour to ascertain what has been our progress in regard to them. The more general diffusion of the majestic family of the palms—those princes of the vegetable world, is fully deserving of precedence on this occasion. I do not refer so much to the introduction of novelties amongst palms, as to the fact that palms are much more generally grown, and that the taste for them is becoming widely extended. They have hitherto been costly, and this has restricted their use, but as demand produces supply, and an abundant supply brings down prices, we may hope to see them come more and more within the reach of all classes. Novelty is not, however, wanting amongst them, for there have been introduced during the last few months some palms of the Lord Howe Islands—notably the Umbrella Palm, *Kentia Canterburyana*—which are of a highly ornamental character, and which have been freely exhibited by some of our chief new plant growers. These we may expect to become popular palms, coming as they do from a group of islands lying nearly five hundred miles outside the tropics, and being, therefore, species not likely to need a high temperature. New stove palms also abound. The plants commonly called *Crotons*—more correctly *Codiaeum*—have lately received some wonderful accessions, such as the *C. Hookeri*, *Veitchii*, multicolor, undulatum, *Johannis*, and others, imported by Messrs. Veitch; and the *C. majesticum* and *spirale*, imported by Mr. Bull. *Dracenas*, too, have been marvellously improved, witness *D. reginae*, *majestica*, *metallica*, *splendens*, *Weismannii*, *amabilis*, and others, which have issued from the two noted Chelsea establishments. In Mr. Bull's *Bertolonia superbissima*, exhibited this year for the first time, we have a real gem amongst beautiful-leaved plants, the habit being dwarf, while the broad, ribbed, deep green leaves are decorated with numerous large and innumerable small, dots of the clearest and most brilliant rose-pink. From amongst the legion of novelties among fine-foliaged plants I select one other for special mention—the *Paulinia thalictroides*, introduced by the Messrs. Veitch, a slender woody hot-house climber, whose stems are draped with leaves resembling the most exquisite of Maidenhair fronds. Amongst recent flowering indoor plants one of the most lovely, for its purity, is the Malayan *Cypripedium niveum*, with its charming waxy-white slipper-formed flowers; and the

Mexican *C. irapeanum*, with beautiful yellow flowers, exhibited by Messrs. Backhouse & Sons. Too much cannot be said in praise of such plants as *Masdevallia Lindenii*, *M. Harryana*, of which Messrs. Veitch and Rollisson show examples, *M. ignea*, and a new one recently shown from Lord Lonsborough's collection—plants which prove to be amongst the most neat-habited and manageable of the cool Orchid race; and whose flowers add to quaintness of form a surprising and almost dazzling brilliancy of colour. *Anthurium Scherzerianum*, the Flamingo plant as it has been called, has won for itself a place in all collections of any pretensions; and in fine contrast with it we now have the more recent *A. ornatum*, which is somewhat larger in growth, has white spathes surrounding spadices of delicate purple-tinted flowers, and is scarcely, if at all, inferior to it in beauty. Then we have the Bromeliaceous *Echmea Maria-reginae*, of M. Wendland, distributed by Mr. Williams—a noble plant of its class, the showy inflorescence of which is set off by the grand rosy-pink bracts which surround it; and *M. Linden's Encholirion corallinum*, another handsome species of the same order, with yellow flowers subtended by coral-red bracts, arranged so as to form a close distichous or flattened spike. Among harder indoor flowers who would, without seeing it, have believed in a Hyacinth with a flower-stem upwards of a yard high, and decorated with a score of massive pendent, pure white bells? Such, however, is the *Hyacinthus candicans*, lately introduced by Mr. Wilson Saunders from South Africa. In this connection, too—that is, amongst the ornamental indoor flowering plants, I must specially mention, as resulting from the skill of the hybridist, *Dipladenia insignis*, the finest of all the forms we yet know of this beautiful genus of hot-house climbers, the colour being of the deepest rosy-carmine, and the size, form, and texture of the flower, irreproachable. *Ixora Colei*, another gardener's triumph, is by far the finest of the white-flowered *Ixoras*, and a splendid exhibition plant, and recently won a substantial prize as the finest object in the Manchester show. Such *Begonias* as Messrs. Veitch's *B. Sedeni*, and Messrs. E. G. Henderson's *B. rubra superba*, fine hybrids of the *holviensis* strain, may be instanced as remarkable for their bold and freely-produced crimson flowers, and as affording evidence how soon the distinctive features of introduced novelties are made the stepping-stones to fresh acquisitions. From this point of view should be noted the splendid varieties of *Euceadonia* and *Plectopoma*, plants allied to *Achimenes*, raised and distributed by M. Van Houtte, but which, with all their beauty, are yet very little known.

Hardy Ferns have been enriched by the many fine varieties of *Scolopendrium*, and latterly of *Adiantum* and *Asplenium* raised by Mr. E. J. Lowe; and of *Athyrium* and *Pteris* by Mr. J. E. Mapplebeck; while amongst tender ferns the grand *Adiantums peruvianum* and *speciosum*, and the equally grand *Davallia Mooriana*—all introduced by Messrs. Veitch—are plants of the highest order of merit from the decorative point of view, and such as will always maintain a position in even the choicest collections of these charming plants.

I must pass on to outdoor plants and flowers, and here the greatest novelty that occurs to me is to be found in Mr. Jackman's race of sweet-scented spring-flowering Clematises, the well-marked fragrance of which may be compared to the combined odours of the Violet and Primrose. As an additional feature of merit in a flower which within the last few years has attained great popularity, the acquisition of fragrance in these varieties of the Clematis deserves prominent mention. I ought here to mention as the best of all hardy evergreens, and only recently brought into prominent notice, Mr. A. Waterer's *Cupressus Lawsoniana erecta viridis*, the most elegant, effective, and refined of all its race, and which has not only stood defiantly and unharmed the severest winter frosts, but passed scatheless through the terribly searching frost of last Whit-Sunday.

For conservatory and terrace decoration, and also, it is said, as a summer bedding plant, few subjects can compare for elegance with the so-called *Amarantus salicifolius*, sent out by Messrs. Veitch, and which, in its brilliant colours and fountain-like aspect, stands unique amongst decorative plants.

One of the finest of hardy perennials of recent introduction, the *Primula japonica*, for the acquisition of which we have to thank Mr. Fortune, is undoubtedly a grand plant, but it seems to have been a little overgrown this season, through being too kindly treated. Like Messrs. Veitch's *Primula cortusoides amena*, however, it bears the stamp of a sterling plant. I gladly refer to the lilies as a family fast retaining the popularity they should never have lost, since they are amongst the very finest of our old garden flowers. They are too numerous to particularise, but I cannot refrain from mentioning *L. tigrinum flore pleno* as one of the finest, while *L. Washingtonianum* is one of the most novel. It is scarcely possible to find a lily which is not worth cultivating, although by comparison some are undoubtedly much finer than others.

Amongst annuals a crimson groundsel, *Senecio pulcher*, with flower heads three inches across, introduced from Uruguay by Mr. Tyerman, is highly promising. I must further mention, as a recent plant, a little annual which, as it has been flowering at Chiswick, has been highly meritorious. I allude to Mr. Thompson's *Leptosiphon roseus*, which for some time past has been a glowing mass of rosy-tinted stars of varied shades.

In the department of fruits, we have to thank Messrs. W. Thomson, Cox, Pearson, Paul, Standish, and others, for varieties of grapes of more or less excellence or promise, the merits of which, however, not being so readily tested as those of flowers, are not so quickly or unanimously decided on. All honour to the efforts made in this direction; and when the raisers of new grapes do succeed in beating a black Hamburg or a white Muscat, there will be no lack of praise, or of more substantial rewards, in store for them. In the meantime, gardeners have to find out for

what purposes the several varieties already obtained are best adapted, and the peculiarities of treatment each requires. I may briefly state that, so far as my observation goes, the general verdict has been in favour of the Madresfield Court Muscat, as likely to prove the best amongst the newer sorts.

Figs are receiving more attention than formerly—perhaps owing to the excellent examples of pot culture produced at Chiswick, some examples of which Mr. Barron has shown us at the Society's provincial shows of former years. Amongst novelties of real excellence in this direction I may note the Royal Vineyard of Messrs. Lee, and the Negro Largo, which Mr. Fleming, who imported it, tells me is the finest black fig in cultivation.

Thanks to the Messrs. Rivers, we have gained many new peaches and nectarines of ascertained merit, but, as in the case of grapes, time is required to bring out their qualities more fully. It would appear that Early Beatrice, Early Rivers, and Early Louise peaches are specially valuable for their earliness; whilst of the new nectarines, the Victoria and the Pine-apple are proved to be valuable acquisitions on the score of quality. A still more recent batch of both peaches and nectarines awaits the judgment of those upon whom it devolves, in our great garden establishments, to keep up a constant supply of good dessert fruit.

I must pass over the other fruits, just to say a word respecting new vegetables, of which the name is legion. It may be well to state that the Royal Horticultural Society has now in hand, at Chiswick, an experimental trial of peas, at which, so far as the earlier sorts are concerned, the following results have already been arrived at, after due examination by the fruit and vegetable committee:—Harbinger has been certificated as being the earliest variety; superlative for its enormous pods, the largest of all the early sorts; and Dr. Hogg, as a fine early wrinkled green marrow. All these have been raised by Mr. Laxton.

Rapid growth of Tree Ferns.—These plants, so precious for the embellishment of large stoves and winter gardens, are generally supposed to be many years old before they produce a good effect, and for the same reason to be only within the reach of the richest amateurs. In the Birmingham Botanic Garden are fine specimens of such giant ferns as *Cibotium regale* and *Alsophila contaminans*, which teach a lesson. Some of these Mexican ferns measure from twelve to twenty feet through, and have fronds more than twelve feet long. Yet, four years ago, they were all small plants in six-inch pots. This is good news for those who have large conservatories, and think it difficult to grace them with such noble ornaments. With good treatment, as is shown by Mr. Latham, they may be grown almost as quickly as a specimen *Pelargonium*.

Indoor Evergreen Walls of Houses.—To turn everything to account and to make every inch, even the back walls of houses under our charge, enjoyable and profitable is one of the duties of every gardener. That this may be done more easily and effectively than by the usual system of brackets I am confident, from the luxuriant appearance of the back wall of a plant stove in these gardens. The wall in question is covered with strong wire about four inches apart and the same distance from the wall; the space next the latter is filled with turfy peat, &c., and in this are large masses of fine foliaged *Begonias*; the Stag's-horn fern, and other plants, also luxuriate in this situation, and the groundwork is densely covered with *Adiantums*, *Pteris*, *Lycopods*, *Panicums*, &c. Fern fronds, always in request, may here be gathered in any quantity; and beyond frequent syringing these walls are scarcely any trouble; in fact, by pegging in the *Lycopods* and filling up any cracks in the soil with a little fresh material, they will last for a number of years.—*JAMES GROOM Henham, Suffolk.*

Silver Sand and Peat in Scotland.—A short time ago I observed an inquiry as to where these could be procured in Scotland. I feel great pleasure in stating that a silver sand, said to be the best in the three kingdoms, may be had in Scotland, at a place called Gartverrie, near Coatbridge. The proprietor of the quarries is Mr. William Lang. Gardeners and others requiring the best, should state "the sand to be burned as for glass-works" in their order. After burning a slight tap knocks it to pieces, and the result is a sand with not a particle of dirt or refuse in it, consisting of the purest silica. A second quality sand is also sold, not burned, but as it comes from the rock. This is largely used by nurserymen for azaleas, camellias, and the finest New Holland plants. It is cheaper than the first, and very serviceable. A gardener here, who was at one time foreman in the New Holland House at Kew, uses the first quality regularly, and says it is much superior to anything he could get about London. There is also a thin bed of peat on the top of this silver-sand rock, finely permeated with the sand, and makes a most excellent staple for azaleas and such like plants, for which it is also largely used by nurserymen. To insure a good sample, however, it would be preferable to take a run over and pick it. I cannot, however, say anything as to its suitability for orchids, never having tried it in that way.—*WILLIAM WRIGHT, Coatbridge.*

GARDEN IN THE HOUSE.

THE FORM AND FURNISHING OF VASES.

PERMIT me to thank "W." and "W. T." for their admirable answers (see p. 578, vol. i.). "W.'s" three general principles of above, below, and on a level with the eye are admirable; and if generally noted and applied would save a world of disappointment. Full half of cut flowers are so placed in regard to the line of vision that their form and character are wholly lost to sight, though still to memory dear. The latter makes such mistakes the more provoking. We remember how nature exhibits their distinctive charms; we see how art hides them by placing the flowers too high or too low, or crowding others over them. I like "W. T.'s" vases, so much as to ask for more. Perhaps hardly a greater service could be rendered to practical gardeners at the present day than giving in these pages descriptions of various styles of vase-dressing. It would add to their value were the height of the vases, the diameter of the mouths, and their general forms indicated. Criticism might also be invited upon the examples given, and every one be considered at liberty to suggest improvements by way of additions or subtractions—in one word, to do it better. As an illustration, I would take the *Gloxinia* and the *Ivy* out of "W. T.'s" vases, and put in a spray of scarlet *Salvia* and a twining branchlet of *Passiflora kermesina* in their stead. Doubtless contrasts of form are allowable as well as of colour; but such contrasts have been carried to great excess; and more variety would result from the giving of each vase a specific character, than from the filling of all with the wholesale mixtures now so common. Perhaps the greatest pleasure would be derived from arranging each vase on the principle of harmony of form and contrast of colour. Then each vase as seen in succession would call up new sensations of pleasure, instead of too often, as now, suggesting another of the same, but worse or better, as the case may be.—*D. T. F.*

Strawberries for Hanging Baskets.—Little bushes of alpine are really pretty plants for house culture, and in a moderately low temperature will produce fruit continuously. I have taken up and potted a good number of plants of both the red and white alpine, and expect that their fruit and flowers will, during the winter, amply repay the little care required in their culture. I should think that those who take so much delight in window plants would try the alpine strawberries. The varieties that produce runners are very pretty when grown in hanging baskets, for the long pendent stems produce a bunch of leaves, flowers, and fruit at every joint, and I am sure the whole appearance of the plants is equal, if not superior to Aaron's beard (*Saxifraga sarmentosa*), *Tradescantia*, and scores of similar plants that are generally cultivated for such purposes.—*W.*

A Floral Ornament for the Drawing-Room.—Last August a lady friend of mine gathered a handful of the world-renowned flowers of forget-me-not, *Myosotis palustris*, and to preserve them for as long a period as possible they were put in a large soap-plate filled with rain-water. The flowers were placed near the window, so as to enjoy the advantages resulting from an abundance of light and air, and the water was replenished when needful. In a surprisingly short space of time—three weeks, I believe—white thread-like roots were emitted from the portion of the flower-stalks in the water, and they ultimately formed a thick network over the plate. The flowers remained quite fresh, excepting a few of the most advanced when gathered, and, as soon as the roots began to run in the water, the buds began to expand, to take the place of those which faded, and up to the middle of November the bouquet—if it may be so called—was a dense mass of flowers, and a more beautiful or chaste ornament for the indoor apartment cannot be imagined.—*Thomas W. Trussler, in "Gardeners' Magazine."*

Gumming Zonal Pelargonium Blooms.—This is often done in Covent Garden Market. Gum is dabbed into the central parts of the blooms of cut flowers with a small brush. By this means the petals are certainly prevented from falling off so soon as they otherwise would do; but the practice is nevertheless a barbarous one. After being dabbed they are spread out on a piece of paper for a few minutes to dry.—*W. F.*

FLOWERS OF LOVELINESS.

O thou sweet Rose in virgin bloom
Thou art a thing to see,
Like *Bella graecæ* in choice costume,
But far the fairer she!

How fair thou art thou canst not tell,
Thou silent senseless Rose;
But she knows how she looks full well:
And that is all she knows.

—*Punch.*

THE GARDENS OF THE VILLA ALBANI, ROME.

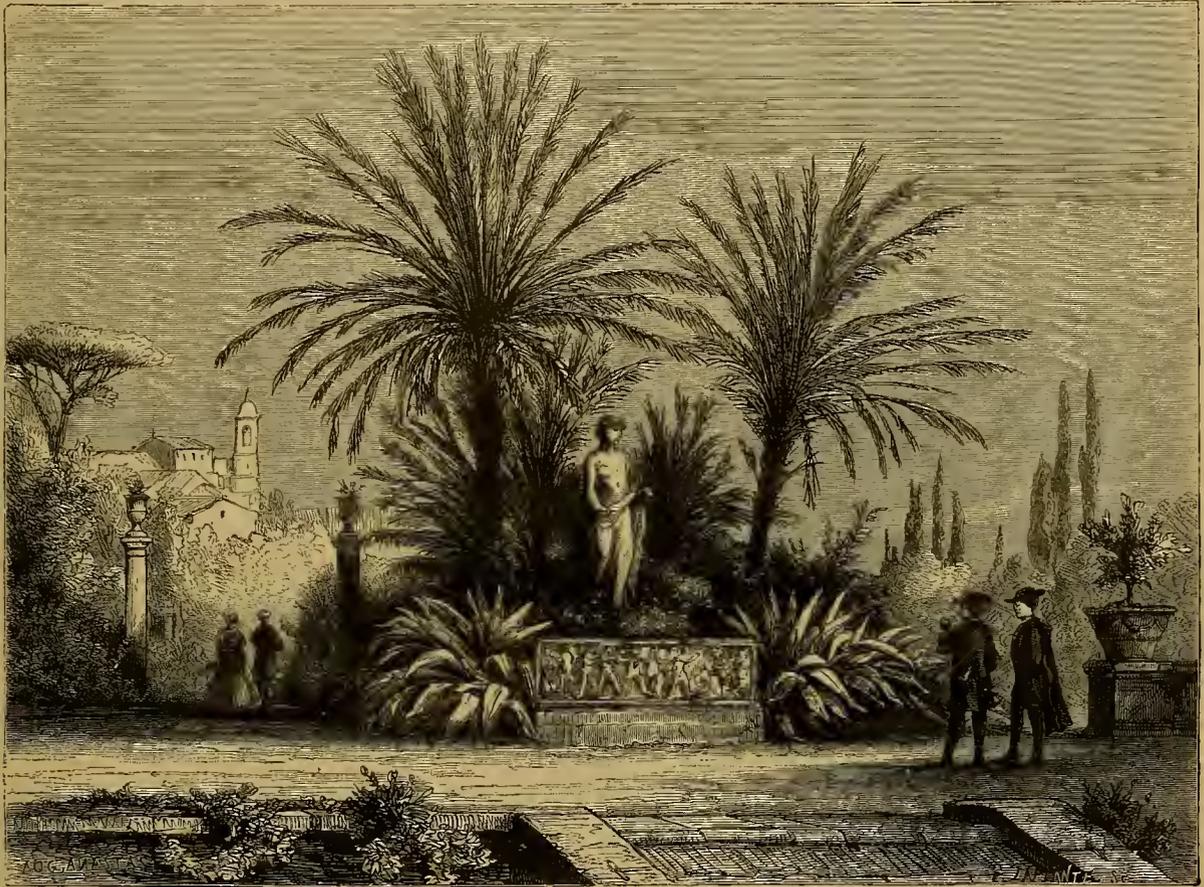

BY NOEL HUMPHREYS.

Among the remarkable private gardens at Rome, that known as the Villa Albani ranks among the most interesting. One of its chief attractions is the fine group of palms, which English tourists, unacquainted with tropical scenery, always look upon with strongly awakened curiosity. We, of the frigid north, as we travel southward, generally make Italy our pleasant pathway in that direction; but it is not till we reach the soft climate of Rome that we witness the feathery foliage of the palm growing in the open air as freely as in the oases of the great African desert, or among the jungles of India, or, as when it forms the chief and most salient point of interest, in the coral islands of intertropical seas.

The aspect of the palm is one of our earliest associations with the graceful glories of tropical vegetation. We first

branch-like leaves. One spot, if my memory serves me aright, is just within the ancient doorway of the convent of St. Onofrio; and another is the Villa Albani; both anxiously sought by the young northern traveller, sketch-book in hand, when the graceful trees have often to submit to many an awkward travesty from clumsy or unpractised pencils.

The Villa Albani is also celebrated for its interesting relics of antique statuary, among which are several well-known masterpieces of antiquity of world-wide celebrity. It was laid out as now seen, and decorated with its treasures of statuary, during the last century, by Cardinal Alessandro Albani, whose well-known *diletantism* found a congenial outlet in the decoration of the gardens of his noble suburban residence with the rarest objects of antique art, collected from all parts of Italy. The accomplished Cardinal also distinguished himself diplomatically during his embassy to the Emperor of Germany,

The Gardens of the Villa Albani, Rome.

become intimate with its solitary, towering stem, and the majestic drooping of its singularly beautiful foliage, in the Bible-pictures of our childhood; and afterwards in those books of travels which form the fascination of early youth, from the voyages of Captain Cook to the later adventures of modern explorers in India, in the Holy Land, and in Egypt. But, except in the confined space of hothouses, and under the artificial protection of glass, few have ever seen the palm in a living and growing state. When, therefore, in Rome, during our first Continental tour, before adventuring to Palestine, Egypt, or India, we find the palm growing freely in the open air in some of the gardens of that city, it seems like the realisation of a dream—like the transformation of some Pygmalion statue to the breathing reality of actual life.

It is only, however, in certain favoured spots in Rome that the palm deigns to display the sweeping glory of its long, feathery,

and as an accomplished bibliographer during his curatorship of the noble library of the Vatican. But it is, after all, by the classical embellishment of his elegant gardens and palace that he is best remembered. He sought to realise a kind of Ciceronian elegance in his abode and its surroundings, seeking to emulate, as he added feature after feature of classic elegance to his gardens and his house, what he conceived to be an embodied reproduction of the Villa of Hadrian, of Cicero's retreat at Tusculum, and Pliny's charming country abode, of which, in his garrulous way, the Roman naturalist has left us so many charming particularities.

But, after all, the charming Villa Albani does not perhaps approach more closely the ancient models of which it was supposed to be a revival than do many other modern Roman villas, though it is undoubtedly one of the most beautiful and interesting. The above engraving will convey a good idea

of the general aspect—of its ancient sarcophagi, wrought about with intricate alto-relievi, flanked and half concealed by great clumps of agaves, growing with tropical luxuriance—of its antique statues of matchless beauty, telling out their snowy outlines against masses of dark evergreen foliage—of its cypresses shooting their tapering spires of foliage into the deep blue Italian sky, and contrasting picturesquely with the tufted heads of the flat-topped stone pines, and most of all, by the artistic treatment of the celebrated group of palms.

THE BIRMINGHAM HORTICULTURAL SHOW.

GARDEN FURNITURE.

VASES, PEDESTALS, FERN-STANDS, FLOWER-BOXES, ETC., IN TERRA, STONWARE, IRON, ETC.

MR. JOHN MATTHEWS, of Weston-super-Mare, exhibited a very fine collection of terra-cotta work, made from the clay near Weston, which he (Mr. Matthews) considers the best in England for plastic purposes. Among the most remarkable of the products of Mr. Matthew's works are the gigantic flower-pots (of the usual shape), thirty inches in diameter, and perfectly unadorned by any kind of ornament; but so finely turned, and baked without the slightest warping, that they are perfect models of the art of simple pottery. These pots only cost £1 each, and in graduated smaller sizes are proportionately lower in price. They are warranted not to become green while in use, and are certainly very fine specimens of the simplest form of ceramic art. The pedestals, at 10s. each, are very decorative, as are the ornamental vases at equally low prices. Fern-stands, with bold basket-pattern sides, and handsome handles (which have a good effect) for lifting them about lawns, are remarkably cheap, only 3s. for a stand thirteen inches in diameter. Six shillings is the price of much larger ones. Little baskets of flowers, of terra-cotta, are made by Mr. Matthews, which though mere playthings, are very curious and beautiful, and serve to show the wonderful plasticity of the Somersetshire clay. Very pretty bed-edgings are to be had at the rate of three farthings, and five farthings, per foot run.

Mr. William Hudspeth, of the South Tyne Works, exhibited a great variety of stoneware, especially his simulated tree stumps, with truncated hollow branches, out of which growing ferns make a picturesque appearance. The tints of this stoneware are very artistic; the rough surface is beautifully modelled, and the hard semi-glaze makes the work perfectly imperishable. The patterns which Mr. Hudspeth calls the "Merlin Oak" and the "Balmoral" are very picturesque and attractive; as are some garden chairs of the same material and analogous design, namely gnarled trunk forms. Fern-stands and rustic vases are also produced, some of them very excellent in design. But there are other devices produced at the South Tyne Works which I am not able to praise. I mean those masses of branchwork upon which an eagle or an owl is perched, having a great aperture in the middle of the back, out of which ferns or other plants are intended to sprout. This sort of thing seems to me the result of very depraved taste; yet it is but justice to Mr. Hudspeth to admit that many of his customers entirely differed from me, and that all his flower-pot eagles and flower-pot owls were marked "sold," and I have reason to know that they had actually found ready purchasers. There was a remarkable piece of rustic fountain-work parts of which were very striking in design, especially in the lower portion, the base of which was formed of gnarled and twisted roots uncommonly well designed. That which struck me most in this handsome rustic fountain, from six to seven feet high, was that the price was only five guineas.

Mr. William Hunt, of Leicester, exhibited a number of very good designs of his remarkably handsome vases, stands, tazzas, &c., formed of massive cast-iron ribs, of very ornamental character. The interstices between the ribs are filled with wirework, through which moss and other small creeping plants show themselves. The advantages of this system of garden-vase structure does not merely consist in its elegance, lightness, and novelty, but in the superior drainage afforded to the plants grown in them.

Messrs. Sankey, of Bulwell Pottery, Notts, exhibited common flower pots, of excellent quality, which can be delivered all over England at the local prices.

Messrs. Doulton & Co. were, as a matter of course, among the most prominent exhibitors. They showed an excellent collection of garden furniture in terra-cotta in all its branches; but what rendered the exhibition less pleasing and instructive was the absence of marked prices on the different articles, so that a visitor was unable to judge, without the irksome trouble of inquiring, one after another, whether the handsome objects were within the limits of his means or not. I took the trouble of inquiring the price of a handsome

mignonette box, three feet long, for which fourteen shillings was the price demanded—a very moderate charge, considering the excellence and elaboration of the design. The Messrs. Doulton's priced catalogue, which there was not time to refer to on the ground, contains good illustrations of most of their leading products.

Mr. Fielding Moore, of Spenny Hill Works, Leicester, exhibited a number of vases, tazzas, pedestals, &c., which I considered very remarkable for the chasteness of their forms, and the delicate character of their small geometrical ornaments, running round the objects, above, under, and between the well-designed mouldings. These chaste and sparingly-introduced borderings are in the style of those found in ancient British and Romano-British pottery. Not the least attractive feature of this class of work is its cheapness. One grand central vase, with an appropriate pedestal, together some five feet high, was marked £1 18s.; and I was pleased to see it sold to an admiring purchaser as I stood by, along with two others of somewhat smaller dimensions, the whole group, as fine a one as could be procured for garden purposes, for only £5. Mr. Moore also manufactures chastely decorated flower-pots of all the ordinary sizes for a trifle less than double the price of the common, unsightly flower-pots used in the wholesale plant trade.

Among the handsomest solid cast-iron vases coloured white in imitation of marble or stone, were those of the Messrs. Handyside & Co. These gentlemen profess to issue a splendidly illustrated catalogue of their productions, which, however, does them no sort of justice. They produce a noble vase, of tall and slender proportions, excessively graceful in its main outline, which is enriched with finely modelled copies of Thorwaldsen's famous groups, "Morning" and "Night." This is a very grand work; but the woodcut in the catalogue, to my mind, conveys no adequate idea of its grandeur. Some of the fountains exhibited by this firm are of large proportions and excellent design. The largest and most important of these was sold on the ground; and I hope many other objects in the collection.

Among the most interesting of the garden furniture in terra-cotta was Mr. Looker's ground viney, which is not only imperishable from the nature of its material, but excellently planned in regard to ventilation. It is said by its inventor, and not without tolerably good reason, to be by far the cheapest and most perfect combination of earthenware and glass for protecting and forcing purposes ever brought before the public. It secures complete ventilation at the ridge, and is easily regulated, without touching or disturbing the glass. I believe that this complete and regulated method of ventilation will greatly facilitate the culture of vines near the ground, which has hitherto been far less successful than it might have been, in consequence of defective ventilation to expel the accumulation of damp vapour.

Messrs. Hebeck & Sons, of Birmingham, exhibited some very handsome stone-coloured vases, with the bas-reliefs in white, which produce a cameo-like effect. Some of them are very effectively bronzed.

ORNAMENTAL GARDEN WIREWORK.

Messrs. Baker & Co., of Chester Street, Aston Road, Birmingham, exhibited by far the largest, and in some respects the best collection of works of this class, and the prices marked on the articles were extremely moderate; every article was priced in conspicuous figures, a principle which led to many sales on the ground, as many of the suspended baskets, one especially with sockets for four lights (24s.), were remarkably cheap. The great rose temple, a structure of very good outline and pretty detail would, as the supporting framework for an elegant bower formed of choice kinds of climbing roses, form a very attractive central object in a rosary; but I should wish to have the wirework, pretty as it is, as much covered as possible with the more natural tracery of rose branches. In concluding my remarks upon this remarkable exhibition of garden wirework, I would recommend Mr. Baker to abstain from such profuse bespatterings with paint and gilding. Though it may attract a certain class of purchasers, I am quite sure that it tends to lower and vitiate taste where it should be the aim of important manufacturers like Mr. Baker to elevate and purify it.

Mr. Walter Fox, of 12, High Holborn, had a small but pretty collection of garden wirework, which was well worthy of examination; as had also Messrs. Ewart & Sons, of Euston Road, remarkable for their moderate price. But the only collection that could for a moment vie with that of Mr. Baker, was exhibited by Mr. Thomas, of Edgware Road, who made a grand display. His "Alexandra Rose Temple" is a very pretty structure; not quite on so large a scale as the similar work exhibited by Mr. Baker, but in some respects of preferable design. The "Temple" is, however, much disfigured and vulgarised by the introduction, at the top of the main supports, and at the apex, of mirrored globes, the top look like great quicksilver pills, these pills being surmounted by gold spikes of equally objectionable and inappropriate character. Tawdry

appendages of this sort should be entirely confined to rose temples intended for tea or beer gardens, and not be allowed to flout their meretricious gaudiness in a public exhibition intended to elevate the public taste. I was happy to observe that Mr. Thomas had many garden elegancies to show us which were entirely free from the blemishes just alluded to, and which were in every way worthy of one of the leading manufacturers in this branch of garden furniture.

H. N. H.

THE FRUIT GARDEN.

THE CURRANT TOMATO.

LOVERS of Tomatoes, and of garden curiosities generally, will be likely to appreciate this distinct kind. It may, like other varieties, be eaten or used in cookery, and it may also be used among cut flowers in vases, &c. It is, too, an agreeable object as a pot plant.

The Currant Tomato.

It is, of course, as easily cultivated as the common kinds. It is much used at Floors Castle, and is highly praised by Mr. Harry Knight, the able gardener there. It is much admired in America, and is figured in the *Agriculturist*.

KEEPING FRUITS.

THE following rules for keeping fruit are from the proceedings of the Royal Horticultural Society:—1. As the flavour of fruit is so easily affected by heterogeneous odours, it is highly desirable that apple and pear rooms should be distinct. 2. The walls and the floor should be annually washed with a solution of quicklime. 3. The room should be perfectly dry, kept at as uniform a temperature as practicable, and be well ventilated, but there should not be a through draught. 4. The utmost care should be taken in gathering the fruit, which should be handled as little as possible. 5. For present use, the fruit should be well ripened; but if for long keeping, it is better, especially with pears, that it should not have arrived at complete maturity. This point, however, requires considerable judgment. 6. No imperfect fruit should be stored with that which is sound, and every more or less decayed specimen should be immediately removed. 7. If placed on shelves, the fruit should not lie more than two deep, and no straw should be used. 8. Where especially clear and beautiful specimens are wanted, they may be packed carefully in dry bran, or in layers of perfectly dry cotton wool, either in closed boxes or in large garden pots. Scutless sawdust will answer the same purpose, but pine sawdust is apt to communicate an unpleasant taste. 9. With care, early apples may be kept till Christmas; while many kinds may be preserved in perfection to a second year.

SUMMER PRUNING OF WALL TREES.

ONE of the most important processes of summer fruit gardening is that relating to the management of "breast wood," as it is called—that is, the young shoots made on the wood of last year, or from spurs. To prevent confusion, it is better not to include in this term leading shoots—those made on the extremities of the growing wood—that are needed to enlarge the size of the tree or to fill up vacant spaces on the walls. These, when of the usual strength, are merely to be tied or nailed in as they grow, to prevent their being injured or broken by winds or rains. When unusually strong, and several branches are needed to occupy the space quickly, it is a good plan to stop these leaders as soon as they have formed from four to six leaves. By pinching out the top several moderate-sized, well-ripened shoots may be obtained, in lieu of one rank branch, that neither ripens nor grows to any useful purpose. Breast wood that is needed for filling up space may be treated in the same way as leaders, moderate shoots being simply carefully attached to the wall or espalier, and strong ones pinched back to force a multiplication of medium growths. Peaches, nectarines, plums, Morello, and it may be other cherries, will have some of their best breast wood laid in thus, and treated in all respects as leaders. The great point in the summer management of all these trees is to provide a succession of bearing wood for next year's crop. So far, and with a view to the formation and furnishing of the tree with fruit-bearing wood in the future, the treatment of breast wood is a far-seeing, selective process, bearing close relation to winter pruning. But much breast wood lies outside of these structural lines. Myriads of shoots burst into branchlets all over the surface of trees. What shall we do with them? A good many answers have been given to this question. It is said that among a multitude of counsellors there is wisdom; but it is equally true that amid a variety of counsel there is uncertainty and confusion. Some say, stop breast wood not at all; others, stop many times, and many, never stop but once. A good deal depends upon the variety, the character of the trees, strong or weak, &c., and the style of training adopted. Peaches and nectarines, for instance, are treated differently from plums and apricots; Morello cherries, from Maydukes or White Hearts; and apples and pears, again, somewhat differently from other fruits. In general the treatment of breast wood on peaches, nectarines, and Morello cherries consists in laying in as much good young wood as room can fairly be found for it, the excess being cut off as useless. Spurs are neither useful nor desirable on such trees. Apricots, plums, and cherries, again, are treated on a sort of hybrid or half-way plan between these and apples and pears.

Breast wood is laid in to fill up blanks, and to provide a succession of fruit-bearing wood. But, in addition to this, the breast wood removed should be cut back to form fruit-bearing spurs at the base. If the shortening back of the breast wood has been done at the right time and in the proper manner, the buds in the axils of these leaves will be all developed into fruit buds before the season of growth is ended, and next year each of these spurs will be developed into a clustering nest full of young fruits. With apples and pears all the breast wood is thus spurred in. The object of this interference with the breast wood of fruit trees is twofold—the admission of more light and warmth to the fruit and leaves left, and the transformation of the wood buds at the base of the breast wood into fruit buds. The practical question, then, is narrowed to this: Which of the modes of stopping is the likeliest to secure these objects? Or should we stop at all? Against not stopping, the shade of the branches is a strong objection; and if the top is bent or broken down, the shadow becomes more dense alike over fruit and leaves. On this ground the plan of bending or breaking down the shoots is objectionable, though the check thus given is mostly sufficient to promote the change of wood into fruit buds at the base of the broken shoot. Trees, also, that have once acquired a thoroughly fruitful habit, or that have been weakened by excessive fruit-bearing, will need no stopping of breast wood to induce greater fertility, and will be strengthened by leaving all growths made alone. But these are the exceptions, and as a rule those who do not stop breast wood, bend or break it down, for the reasons given. The untidiness of the plan is another objection against it, and it is one that I cannot recommend to your readers, as few things look more slovenly than half-broken branches dangling against the wall.

D. T. FISH.

STRAWBERRY FORCING IN SURREY.

AMONG representative industries is that of forcing strawberries; and we have just paid a visit to Mr. Dew's establishment at Ham, where he has successfully carried on this industry for these last forty years. The long glass-houses filled with rows of pots, each of the latter containing a single plant loaded with luscious ripe fruit, hanging in rich clusters beneath the dark green leaves, is a beautiful sight; the

aroma is simply delicious, indeed, at times, almost overpowering. Here we have this queen of fruits without the only drawback that it is ever possible to attribute to it—the growing so close to the earth, which often gives, in rainy weather, an unmistakable grittiness to the berries. The forced strawberry is perfection; it loses none of its natural good qualities by being grown under glass, and invites you irresistibly to eat it by its tempting appearance. This season has proved an excellent one in every way for this particular industry; the fruit is large and well flavoured, and the demand so great that three times the quantity sent to market would have met a ready sale; this, considering the high price at which forced strawberries are necessarily sold to repay the great expenses of cultivation and leave a profit, speaks well for the wealth of the nation. Even a very short time ago Sir Charles Napier was fetching eight shillings a pound, wholesale. The 10th of last March was the day on which the gathering of ripe fruit commenced, and it is still being daily picked and sent to market. To supply the tables of the rich with this delicacy, the work to ensure next year's crop has already commenced, and men and horses are busily engaged carting the fuel which is to protect the plants from next winter's frosts. To take a delight in eating strawberries, which, when they first arrive in the market, average a shilling each, may appear like eating money; but directly we look below the surface, we find how very beneficial to the community at large are the luxuries indulged in by the more wealthy. At this present season the number of persons employed in preparing for the cultivation of next year's fruit, makes plenty in many homes; indeed, Ham Street, as the road is called leading from Ham Common to Mr. Dew's, seems to be a village of gardeners, for the greater number of inhabitants find at one season or the other employment in his grounds. Those who are fortunate enough to be able to afford forced strawberries should this year make much of them, for we fear the outdoor crop will prove but scanty; indeed, Mr. Dew told us it has been a bad season with almost all open-air crops: asparagus has not yielded one-quarter of the usual quantity; gooseberries and currants, which at the beginning of April promised a heavy return, are much injured by the severe frosts we had in the spring; apples are almost all affected with maggot, and pears alone, out of all the outdoor fruits, promise anything like a remunerative crop. Market gardening in seasons like the present must indeed be an uncertain business.

Only the very strongest and finest plants are selected for being forced, and, as the season advances, Mr. Dew's gardens begin to resemble the ancient garden of Maréchal de Biron, who flanked his walks with nine thousand pots of asters, only the former flanks his garden walks with never less than twenty thousand pots of strawberry plants, and during the summer their dark shining foliage affords a pleasing contrast to the mass of brilliant flowers and bright variegated leaves of the bedding-out plants in the borders. No sooner do shortening days and cold weather begin than all the strawberry plants are placed in frames, and covered carefully at night; from these quarters they are shifted to the forcing-houses at the beginning of December; fires are lighted, frosts jealously excluded, and the onerous work of forcing begins. We wonder if those who eat these forced fruits ever think of the months of care and unremitting labour involved in producing them. While they are enjoying Christmas festivities, or reclining on their downy couch, the gardener is hard at work. The plants having been safely housed, and the fires lit, unceasing care is required to keep the temperature even, and during the long wet or cold frosty nights of winter the fires requires continual care. About every two hours the man in charge must go his rounds and see that all is well; the slightest carelessness may involve a great loss, and fifty pounds' worth of strawberries has been lost in one night through negligence. When the truss, or head of flowers appears, and during the whole time of growth, until the fruit begins to colour, the plants are copiously watered overhead with clear water. The fruit for market is begun to be gathered at four o'clock in the morning, and before the end of the season many tons have been disposed of.—*Knife and Fork.*

THE COLOUR OF GRAPES.

COLOUR is sure to be found in conjunction with high flavour and other good qualities, if the grapes are ripe; for it must be borne in mind that black grapes get black before they are fully ripe. There seems to be no doubt, either, that high finish is a sure sign of vigour in the vine; for that deep black colour and purple bloom is never, as far as my experience goes, found on weakly vines, or in conjunction with a too heavy crop of fruit. I have seen Hamburg grapes ripe, yet nearly green, simply through allowing the vines to carry an excessive crop. Two or three years ago I saw a house of grapes, Hamburgs, belonging to an amateur, in which there was not one bunch that had even got as red as a grizzly Frontignan, and many of the bunches

had scarcely a tinge of colour about them at all, but remained green almost to the last. The berries tasted sweet, but that was the highest praise that could be given them—globules of sugar and water, for they could not be called fleshy. Considering the strength of the vines, the crop was, however, the heaviest I ever saw. Every bunch had been allowed to remain, two and three on a shoot, and every grape-grower knows what that means. The berries had been thinned to some extent, but that was all. Great stress is laid by many upon light and air as colouring agents, and I certainly do not undervalue their importance in this respect; but the most thorough ventilation and exposure just when the grapes begin to colour, as commonly practised, is of little avail if other matters have been neglected. Plenty of light and air, acting upon the foliage, without doubt promote a vigorous constitution in the plant, and indirectly materially assist the colouring process, but the mere action of either upon the fruit itself seems to be very unimportant indeed; otherwise, in fine and bright seasons we might expect the best-finished crops, but such is not by any means the case. Black grapes ripened in January are often quite as highly coloured as those ripened in summer and autumn. In spite of the exceptionally dull weather we have had this season so far, our early grapes, on both pot and permanent vines, have coloured exceedingly well, and better than they have done on more favourable occasions. Light has certainly been deficient during the past spring, and ventilation necessarily restricted. Again, varieties differ greatly in regard to their colouring power, so to speak. The black Hamburg is susceptible of the deepest black and the densest bloom under favourable conditions; but it is oftener seen only red, which has encouraged a belief that there is a red Hamburg, though in all probability no such variety exists. We have at least often seen "red" Hamburgs turn black under altered circumstances. The Muscat Hamburg is another grape which, among other bad qualities, has that of colouring indifferently. Mrs. Pince, too, frequently gets only red. I have this grape here on its own roots, and grafted upon the Alicante and on the Lady Downe's. On the first it is simply bad as a setter and in colour. On the Alicante the bunches are invariably magnificent, except in colour, though better in this respect than on its own roots; but often reddish when the grapes on the Alicante limb of the same vine are quite black. On the Lady Downe's stock the bunches are smaller, and more cylindrical; but they always finish best and keep longest. On its own roots it has a high and delicious Muscat flavour, but it is less piquant on the other stocks. Mrs. Pince is, however, most erratic in this respect, for we have tested it at other places and on other stocks, and failed to detect the slightest Muscat flavour about it. West's St. Peter is one of the best to colour, and takes on a singularly beautiful metallic lustre when well finished that no other grape does. The Royal Ascot would appear to be a favourite in this respect also. Barbarossa, in some soils and situations, is a grape which finishes exceedingly well, taking on the most extraordinary bloom we ever saw. Among white grapes perfect finish is even more uncommon than among the blacks. Taking the Muscat of Alexandria as the type of this section, how seldom do we see it of that deep yet transparent amber colour, which indicates perfection and high flavour? Buckland's Sweetwater grape is one that, as a rule, finishes well, and has a very taking colour when quite ripe. That magnificent grape, the Golden Champion, is certainly worthy of its name, but for the constitutional speck which affects the berries when just about ripe. I have had it, however, and seen it on several occasions, without blemish. My experience is that it is a grape which requires time and a somewhat dry atmosphere to finish it properly. It is at least a month later than the black Hamburg, and it will not bear hurrying. By far the best stock for it is the Muscat of Alexandria. Upon the whole, we are as yet in the dark to a great extent concerning the colour of both fruits and flowers. The directly operating agents in its production are a mystery, but it is a well-ascertained fact that the general health of the subject has much to do with the intensity or brilliancy of the hue, whatever it may be; and this should be constantly kept in mind by the grape-grower who would wish to secure a good sample; while he must not forget that his prospects, however fair at the commencement, may be blighted at the last by having too heavy a crop on the vines, or by subjecting them to a high and hurrying temperature, which alone is sure to impair both weight or colour, and, I should add, flavour.

J. S.

Rust on Grapes.—No one should thin Grapes without the head being securely wrapped with a clean handkerchief, to keep the hair from coming in contact with the berries. As for fingering or handling, by all means avoid it; a tapering piece of wood about the thickness of a penholder will suffice to hold or turn the bunch about in any required direction. I admit that excessive treatment in any particular way may produce rust, but it may, as a rule, be attributed to the causes put forward by Mr. Edward Jackson (see p. 682). In thinning Grapes it is astonishing the difference produced on them by different operators.—THOMAS J. CAPARN, *Newark-on-Trent.*

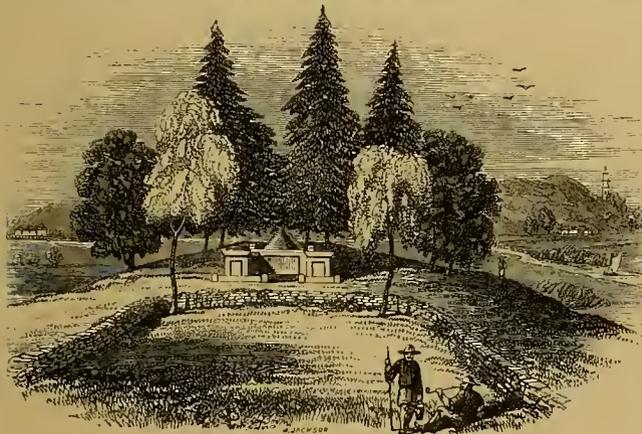

THE ARBORETUM.

EFFECT OF THE PAST WINTER ON EVERGREENS IN AMERICA.

THE unusual loss of evergreens noticed by Mr. Sargent in *THE GARDEN* of June 5th, has been quite general throughout the Northern, Middle, and Western States; particularly where little or no snow fell during the winter. In this respect the season was a somewhat remarkable one. The frosts, in consequence, were particularly severe, very few of the varieties of our native and hardy foreign evergreens escaping, except the Austrian pine, which seems to have suffered but little, owing perhaps to its less fibrous and more penetrating roots. The Central Park, New York, and Prospect Park, Brooklyn, have both suffered severely, taking into account the numbers planted; of course, the more tender varieties suffered most. Recent inquiries into the condition of the stock in many of our largest nurseries in different parts of the country, correspond with the general experience in the two parks just named. In the latter part of February, an agreeable change of weather for a few days gave a very encouraging appearance to vegetation, but as late as the first week in March we experienced the severest frost of the season, which, added to the want of moisture at the time, due to the absence of snow and the drying winds peculiar to that month, seems to have exhausted all remaining vitality, and to have completely destroyed the recuperative powers of those plants, which the advent of fine weather seemed to encourage.—JOHN Y. CULYER, *Chief Engineer, Brooklyn Park.*

THE FUNERAL CYPRESS AT A CHINESE TOMB.

THE accompanying little sketch (after Fortune) of the Funeral Cypress, as employed by the Chinese gives a better idea of the habit of the tree than the woodcut we gave last week. It is to be regretted that so graceful a tree is not hardy everywhere with us. Varieties

Chinese Tomb (after Fortune).

of some of our hardiest pines with a weeping habit are greatly to be desired, and we trust that in time many such may be detected and increased by our nurserymen. The few we have already are far too little known and employed.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE WOLGA CALOPHACA (CALOPHACA WOLGARICA).

This forms a pretty, slender, spreading, deciduous shrub, from two to three feet high when on its own roots, but when grafted standard high on the laburnum, it forms a very singular and beautiful object, either when covered with its yellow blossoms in June, or with its fine reddish pods in August. It is a native of Siberia, where it grows on dry gravelly hills near the rivers Wolga and Don. It was first introduced in 1780. It grows well in any good garden soil, and is increased either by grafting it on the laburnum, or by means of seeds, which are produced freely in most seasons. The leaves are alternate, pinnate, and terminated by a small acute spine-like point, and a pair of lanceolate stipules at the base; the leaflets are small, orbicular, and entire, with a small acute spine-like point; they are smooth on the upper surface, velvety beneath, and mostly

in seven opposite pairs. The flowers are pea-shaped, bright yellow, and produced in axillary pedunculate racemes, containing from seven to ten flowers. The legumes or pods are oblong, somewhat cylindrical, with a sharp bristle-like point, and stalkless; when young they are beset with soft hairs mixed with stiff glandular bristles, and are of a bright reddish colour; the seeds are ripe by the end of August. Its synonyms are *Cytisus volgaricus* and *pinnatus*. The name "*Calophaca*" is derived from "*kalos*," beautiful, and "*phake*," a lentil, in allusion to the beauty of the plant when covered with its pea-like blossoms and reddish pods.

THE SCARLET BERRIED ELDER (SAMBUCUS RACEMOSA).

This forms a low tree, or large bush from ten to fifteen feet high, which grows as freely as the common Elder in any ordinary garden soil, and is as easily increased. When trained to a single stem, and covered with panicles of fine large berries, which resemble miniature bunches of grapes of the most brilliant scarlet, it has a splendid appearance. It is a native of mountainous in the middle and south of Europe, and was first introduced in 1596. The leaves are opposite, rather large, pinnate, tolerably smooth and pale green, with five oblong, acuminate deeply serrated leaflets, unequal at the base. The flowers are borne in terminal ovate panicles, whitish-green in colour, and they are produced in May. The berries are globular, succulent, comparatively large, bright scarlet, and are ripe in August.

Silver-Bell Trees. — The Two-winged Halesia. — The common Silver-bell Tree (*Halesia tetraptera*), sometimes improperly called "*Snowdrop*," is not by any means rare. In May its branches are completely loaded with white, pendulous, bell-like flowers, which are succeeded by a four-winged capsule. This species is found from Virginia southward, especially along the banks of rivers, where it forms a small tree from ten to thirty feet high. Farther south, in Georgia and some other States, is found the Two-winged Silver-bell (*Halesia diptera*), which has larger leaves and much larger flowers, which are an inch or more in length, and which is distinguished by its strongly two-winged fruit. There are other characters which distinguish the two species, but it is unnecessary to mention any but the most obvious ones. The last-named species is seldom to be obtained in nurseries, which is to be regretted, as, on account of its larger flowers, it is a much finer ornamental shrub than the other. The genus *Halesia* was named in honour of Stephen Hales, whose experiments upon the evaporation of water by foliage are so often referred to. The specific names refer to the number of wings upon the fruit.—*Hearth and Home.*—[*Halesia tetraptera* has been described by Mr. Gordon, in *THE GARDEN* (see p. 392). It is universally called *Snowdrop tree* in England and *Silver-bell* in America. The *Halesia diptera* is more or less tender in the climate of London, and only flowers when trained to a wall with a favourable aspect. There was at one time a fine plant of it trained against a wall in the nursery of the late Messrs. Loddiges, of Hackney. Several years ago it was generally known under the name of *Styrax grandifolium*, which is, however, a very different plant.]

The Derby Arboretum Anniversary.—This was celebrated the other day under a downpour of rain accompanied by thunder and lightning, a circumstance which, however, does not seem to have greatly affected the funds. The following are the actual sums which have been paid into the bank during the last ten years:—

Number admitted.			Money taken.			Number admitted.			Money taken.		
	£	s.	£	s.	d.		£	s.	£	s.	d.
1863	25,000	560	19	6		1868	22,000	542	17	3	
1864	31,000	642	0	0		1869	32,900	673	0	9	
1865	30,400	552	6	6		1870	31,500	660	0	6	
1866	23,572	623	1	9		1871	18,000	400	0	0	
1867	21,975	550	12	7		1872	30,000	640	17	3	

Here and there were presented unmistakable evidences of the storm, and also of the presence of British excursionists, who are not over scrupulous in their treatment of shrubberies and flower-beds.

The Decdar.—In answer to your correspondent "*Cedrus*" (vol. i., p. 558), I should advise him to have seedling Decdars, as they grow faster and make much more handsome trees than those produced either from grafts or cuttings. Of course, he can get them by either of these ways, but they seldom make good well-branched trees, and only assume the character of a branch. Most of the fir tribe can be propagated in this way, but the plants are generally disfigured; and to give them a tree-like appearance, they require great attention in pruning and tying their branches, and often then without effect. Therefore, if good, fast-growing, well-branched trees are the object, by all means have seedlings.—J. TAYLOR, *Maesgwynne, Whitland.*

THE KITCHEN GARDEN.

CULTURE OF SPINACH.

In order to keep up an everyday supply of Spinach all the year round, sow the last summer crop on a well-prepared border or quarter about the middle of this month, in drills about eighteen inches apart; this will yield a good supply of fine large leaves till October is out. For the late or winter crop prepare about the end of the month a border or sheltered quarter; apply a good coating of thoroughly decayed manure, trench the ground well and cast it up into ridges, so as to expose as great a surface as possible to the influence of the atmosphere. Every dry day till August 10th or 12th cast down the ridges and pulverise with a steel fork, so as to sweeten and incorporate all together. Then draw lines a foot apart and sow the hardy Prickly variety. As the plants advance thin them out from six to nine inches apart, and maintain a healthy and vigorous growth by constant surface stirrings in suitable weather; this, if attended to, prevents canker, and encourages the production of abundance of fine leaves for use every day throughout the winter. Timely forethought should be taken to shelter a portion with a row of short stakes about eighteen inches high, interwoven with fern, straw, evergreen branches, furze, heath, or other material, which should be neatly applied, and also made wind-proof. Thatched hurdles or frames, cheaply made, of battens backed together and thatched, might also be used for the purpose of protecting from frost. Make another good sowing of the same hardy Spinach on ground as well prepared as the last, about August 20th or 22nd, in lines a foot apart, and thin out to four or six inches between the plants. This will furnish a supply for use next spring, for although there is only the short period of eight or ten days between this sowing and the last, this one will yield but very little before spring. To keep up a regular supply in summer, sow the round Spinach on a warm sheltered border and between lines of Early Peas, &c., once a fortnight from February to May, and for the next six weeks after that on the coldest and dampest part of the garden; and if a north aspect can be provided, so much the better.

In March sow New Zealand Spinach in heat; pot off, and encourage the growth of a few plants till about the middle of April; a very few plants will produce an enormous quantity of leaves if turned out on a slight hot-bed, as is done with ridge Cucumbers, and let hand-glasses be placed over them until strongly started and well established. The hotter and drier the weather, the stronger will this Spinach grow, a circumstance quite at variance with the winter and summer varieties, which "bolt" or start to seed at an early stage in hot weather and in warm situations, particularly on light or poor soils, or when under shallow culture.

Another famous substitute for Spinach in summer is the foliage of the Silesian White Beet, a row or two of which will produce a quantity of fine clean healthy leaves in the heat of summer. In autumn the silvery clean white stalks of this famous Beet make a very good substitute for Seakale; they are served at table in the same way, and make a capital wholesome dish. JAMES BARNES.

Watering and Mulching.—Waterings, effectual but not frequent, and stirring the surface or mulching immediately afterwards, form the secret of success in droughty seasons. Mulching in itself has a wonderful effect on nearly all kinds of vegetable crops, and notably on peas, all the Brassica tribe, celery, and potatoes. The handiest material for such purposes is short grass, which is always plentiful. A good mulching of this between the potato rows, instead of earthing them up, increases the weight of the crop largely, but it is a disadvantage in wet seasons. Raspberries luxuriate under a thick mulching of grass, which is worth a heavy dressing of manure to such moisture-loving plants. Strawberries are equally benefited by the same treatment, and the mulching should be done early in spring in their case. On apples, pears, gooseberries, and currants, in shallow warm soils, a top dressing of any loose material seems to work little less than a miracle. Indeed, such a practice is commendable under almost any circumstances, and at all times saves an immense amount of labour in watering.—J. S. W.

Earthing up Celery.—Will you be good enough to answer the following questions: Is it, or is it not, necessary to earth up celery while it is growing? or should the operation be delayed until the plant is nearly ready for pulling? If not absolutely necessary, is it better to earth gradually from time to time, or all at once two or three weeks before using? I am aware that these questions are answered by anticipation in several good treatises on gardening—Sir J. Paxton's among the rest; but, strange to say, the practice of delaying the earthing, which they all recommend, is contrary to that of every practical gardener I have spoken to on the subject. All my

neighbours earth their celery, and by degrees; and an old professional gardener of some fifty years' experience advises me to do the same. What am I to do?—E. G.—[It is certainly not necessary to earth up celery when it is growing rapidly; more than that, it is bad practice. A little sprinkling of earth, pushed down after a heavy watering to prevent evaporation, is all we should give during the growing season, and we know it to be a fact that some of those who grow the finest celery in the country, do not earth till full growth is attained. Indeed, some of them do not earth at all, but effect the blanching by other means. That some old professionals of fifty years' experience, and many other persons, pursue quite a different course, we are well aware, yet one would think that a single hint would suffice to point out that it is difficult to give abundant waterings to celery, and impossible for it to benefit by the natural rains, if we pile a sharply-sloping bank of firm earth close along each line long before the plants have attained maturity or vigour. And no plant is more benefited by profuse waterings than this, naturally an inhabitant of very wet places. The repeated earthings which celery receives in the majority of gardens are not only harmful to the celery, but the cause of a great waste of time and labour.]

Crops for Poor Land.—Will you or any of your market-gardening readers tell me what is the best crop for poor land?—L. H.—[An ordinary crop of onions is worth about £40 or £50 per acre. On poor land onions pay better than any other vegetable. 1. On an acre of ground during the summer, onions will produce £40; during winter, lettuce and spinach, £20; total, £60; 2. On the same amount of ground, cabbages in summer will fetch £30; the same in winter, £10; total, £40. 3. On the same, potatoes in summer will realise £20; lettuces in winter, £20; total, £40. The labour of the second and third is much greater, and requires better land than the first.]

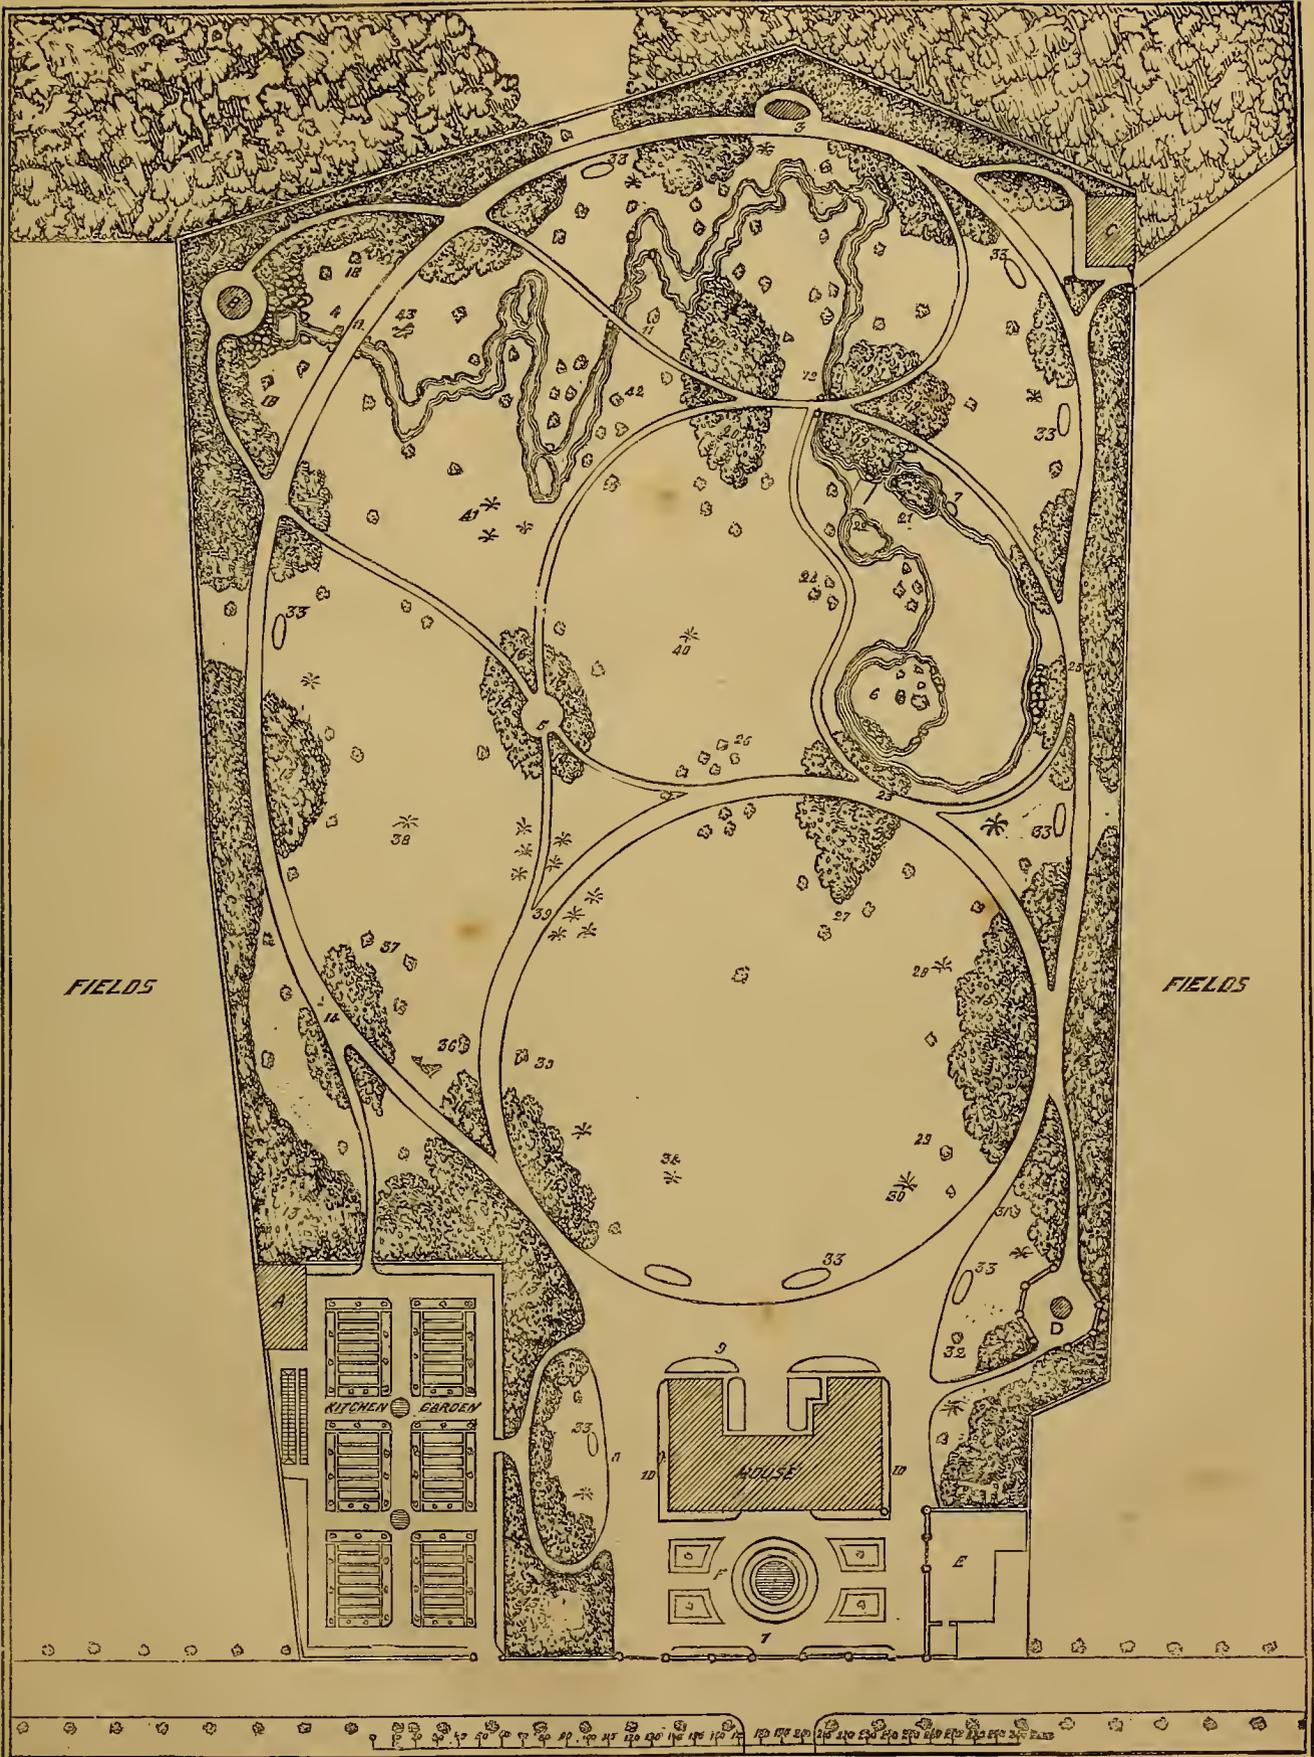

Lettuces.—Careful trials of many sorts of cos and cabbage lettuces, spread over several years, and continued during the present summer, have shown that most of the so-called new kinds of white cos are, after all, but mere selections from the old Paris white cos. The two best strains are Waite's Alexandra and Dimmick's Victoria, the first being exceedingly even, true, and slow to run to seed. The latter also inherits most of these qualities, but it is specially to be commended for its great size and usefulness for exhibition. Of winter cos lettuces the largest and best are Acme, white cos, a very fine hardy variety, and Sugarloaf, brown cos, a strain of the black-seeded Bath cos. Neither of these require tying, and they are without exception, first-rate. Among cabbage lettuces, the best in my opinion is Leyden White Dutch for the very earliest. If sown with the summer white cos kinds, it will be ready for cutting a fortnight before them. And with it also sow Victoria cabbage lettuce, a fine solid kind, but several days later, and one which stands well. For winter work sow in the end of July and beginning of August Stanstead Park brown cabbage lettuce, the finest grown, and with it, Fearnought cabbage lettuce, which is much like the last, but stands longer. Than these no better selection can be made.—A. D.

Radishes.—Kindly give me some information as to the best mode of growing Radishes. I have never yet been able to get a good crop, although I have tried in good and in bad soil, in all situations and in all seasons. I can grow as fine a crop of tops as anyone, and as much seed as would sow any market garden near London; but as to the needful there is nothing but small wiry roots.—R. F., Everton.

GARDEN DESIGN.

A GARDEN AT RAMBOUILLET, NEAR PARIS.

OUR plan this week is that of a garden near Paris, which may be considered as a fair example of the modern French garden. It will be seen that it has many good features, and that indeed it could not be easily found fault with, if it were not that the centre is too much broken up by the intersections of the walks. By way of justifying the existence of so many walks, our French friends tell us that it is necessary to have many more walks in France than in England, in consequence of the absence of as good a turf as we possess, and that in the absence of turf on which to walk it is necessary to have more walks. We see little force in these explanations, as we have seen very charming lawns near Paris, even in the parks and on the race-courses. We have, we are glad to say, seen some French gardens in which this obviously objectionable system did not exist, as, for example, in the Little Trianon, and also in Rothschild's garden in the Bois de Boulogne. The most redeeming feature about the plan in question is the good attempts made at concealing their intersections. We may point out the graceful way of grouping and isolating trees

A MODERN FRENCH GARDEN.

shown in this plan. The water, too, is well treated in all parts. The absence, moreover, of any geometrical patterns of beds about the ground is noteworthy, and a real advance in ornamental gardening. We must, of course, have beds for flowers in such places, but it is better to rest content with a simple form like the ovals here shown, and to depend for effect on the plants we put into the beds than in any degree to depend on the mere contour of the beds themselves.

The following are the references to the plan, which is the work of our talented friend, M. Edouard André, ceaseless worker, horticulturist, botanist, and landscape gardener.

We do not include in this list herbaceous plants, those by the side of the ornamental water, small isolated shrubs, &c.

THE ROYAL GARDENS, KEW.

DR. HOOKER AND MR. AYRTON.

THE public, says the *Times*, will hear with regret that, since Mr. Ayrton's appointment to the post of First Commissioner of Works, such difficulties have arisen with respect to the management of Kew Gardens as to occasion imminent danger of Dr. Hooker's resignation. We state the facts as they are at present known, subject to correction by future explanations; but the correspondence which has passed with the Treasury leaves little doubt of their substantial accuracy. One of Mr. Ayrton's first acts after taking office was to send a reprimand to Dr. Hooker. It is said the occasion was supplied entirely by the First Commissioner's own misconception; but, at all events, it was the first experience of the kind during Dr. Hooker's thirty years of service. But more material acts of interference followed. A previous First Commissioner had intrusted Dr. Hooker with the task of remodelling the heating apparatus throughout the establishment; and, in accordance with the director's plans and estimates, a range of hothouse was constructed which is the completest in existence for scientific purposes. In 1871, without any notice being given him or any reason assigned, he was superseded in the control of this apparatus, and he was left to discover his supersession accidentally, through one of his own subordinates. On addressing an inquiry to the First Commissioner, he was simply informed that he had been superseded, and would have to govern himself accordingly. Dr. Hooker seems to have reason in arguing that to trust a cultivator with the care and treatment of valuable collections, and to make him amenable to the opinions of others in respect of the apparatus he requires, is as wrong in principle as to refuse a surgeon his choice of instruments and hospital appliances. But, at all events, courtesy and justice alike required that Dr. Hooker should have been consulted before the change was made. It would seem, in fact, that in 1870 a director of works was appointed under the Board of Works, and that measures were taken to re-organize the management of the gardens. It is alleged that since then the curator has been removed from his duties under Dr. Hooker without any previous communication, and has been empowered in various respects to act independently. Plans and estimates were submitted to the Treasury for extensive alterations in the Museum at Kew, without Dr. Hooker being so much as informed of the intention. These works, it is said, would have greatly embarrassed him as director of the museum, and they were eventually abandoned on reference to Mr. Stansfeld. It is even alleged that Mr. Ayrton invited the curator to accept a position which would have involved authority over the works at Kew, requesting him, at the same time, to keep the invitation from the knowledge of Dr. Hooker. In short, Dr. Hooker charges Mr. Ayrton with "evasion, misrepresentation, and mis-statements" in his communications on the subject to Mr. Gladstone, with ungracious and offensive conduct towards himself, and with acts injurious to the public service and tending to the subversion of discipline. Mr. Gladstone, having been appealed to, referred the matter at last to a committee of the Cabinet. After their inquiry Mr. Ayrton was told that Dr. Hooker should in all respects be

treated as the head of the local establishment at Kew, of course in subordination to the First Commissioner of Works. But Dr. Hooker, not unnaturally, wishes to be more definitely informed respecting his future duties and relations to Mr. Ayrton; and he has addressed distinct inquiries to the Treasury whether he is to have restored to him the control of the heating apparatus, whether he is to be consulted respecting estimates, whether he is still to be intrusted with the custody and distribution of scientific works, whether he is to be consulted in case of proposed changes in the position and duties of his subordinates and in case of proposed works which would affect his duties and responsibilities, and whether he or the director of works is to have control in matters for which they are jointly responsible.

We shall not follow the *Times*, says the *Echo*, in giving a premature judgment upon the difficulty that has arisen between Mr. Ayrton and Dr. Hooker, of Kew Gardens. There is probably no department of the public service in which there is not, in the public interest, a demand for unpleasant work; for pruning the unwholesome growth of years of unchecked extravagance. It is not likely that we shall get this unpleasant work well done if we are hasty to find fault with the reforming Minister. Let us hear what Mr. Ayrton has to say for himself. We may depend upon it that we shall never get an economical Minister, whose *modus operandi* will be pleasant to the permanent officers of the Civil Service.

The Thames Embankment.—The Metropolitan Board of Works has been recently considering the question of the supply of trees and plants for the ornamentation of the Victoria and Albert Embankments. A statement having been made that the charges for the trees and plants supplied were excessive, and the supply itself deficient, the matter was referred to a committee for investigation. This committee finds, in the first place, that the charges, although high, are not unreasonable; and that their amount is due to the fact that the plants, in order to be transplanted properly, had to be conveyed in their own earth, which involved considerable additional expenditure. The deficiency in the number of the plants is attributed by the committee to three causes—first, to the haste with which they were planted, in consequence of which many of the plants were put into land not always thoroughly adapted to their characters; secondly, to the inclemency of the weather, which killed a large number of the remainder; and thirdly, to the hostility of the roughs, who stole or destroyed the rest. The prospect, we fear, is not a very hopeful one. A recurrence of the first of these causes may perhaps be avoided for the future by the exercise of greater deliberation and judgment on the part of the board; but the severity of English summers has now grown proverbial; and at present, unfortunately, our roughs seem almost as little under our control as our weather. Perhaps the only course to be pursued is for the board to keep a constant supply of plants on hand to replace those which it may please our masters from time to time to destroy or carry off, and to await with patience the time when the plants shall have grown too big to be removed, and when perhaps the tempting facilities which they will then offer to the roughs for hacking their names upon and otherwise defacing them will enlist the sympathies of the latter in the cause of their maintenance.—*Pall Mall Gazette*.

Our Gardens.—A nation which loves gardens as we English do is blessed with a taste of which the influence may be said to be wholly beneficial, and to the development of which there need be no limits. We have a climate and soil which permit of our exercising our propensity to an extent almost impracticable elsewhere. A little further south it is too hot and dry; a little further north too cold and stormy. Even in Canada and the States the alternations of heat and cold are too great for most of our flowers, and after a fortnight of spring, comes the burning summer, to scorch up every delicate plant. Nowhere in the world, save in the Low Countries, and some parts of Germany, is their grass like ours. The queen of a southern country spent hundreds of pounds in vain to deck her palace garden with a rood of such sward as covers half the vales of England. The grandest trees of the world, from the Himalayan pine to the giant Sequoia (Wellingtonia) of California, will flourish on our soil as freely as our own glorious oaks and elms and beeches and limes, and every year adds to our treasures, inasmuch that if old Evelyn were to awake he would have had a new science of arboriculture to learn, and Bacon might write another essay on the Garden, with a new world of sweet and lovely flowers to describe. Like the paradise spot in which grew Shelley's "Sensitive Plant," England may boast that

"All sweet flowers, from every clime,
Grow in that garden in perfect prime."

We have, in truth, a garden-island, "girded by the inviolate sea"—a land which is to the rest of the world much what the Isle of Wight is to England; and heartily may we be thankful that so it is. Against our gloomy skies, our smoke-begrimed cities, our over-busy and toilsome lives, we can set the gardens of England—and the balance is not wholly against us even in the matter of beauty and enjoyment.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.

PRIVATE GARDENS.

Indoor Plant Department.—Conservatories now exhibit more green leaves than showy flowers; every attention is therefore paid to keeping the foliage clear of insects of all sorts, and to the encouragement of its healthy development. The *Clianthus puniceus* is a plant very liable to attacks of red spider, and must, therefore, be closely watched and often syringed. Plants in pots are more likely to suffer from drought at this season than those in borders, and must, therefore, be frequently examined. Tree Ferns, some Palms, and a few quick-growing large plants in borders, should have basins of earth formed round their bases, so that a thorough soaking of water can be given to them at one time without running over the border. Fuchsias, both in the form of climbers and pyramids, are now about their best. Pinch their side-shoots in freely until a few weeks prior to allowing them to bloom, and give a little liquid manure about twice a week. In growing the double-flowering kinds of Pelargoniums, endeavour to induce a stubby growth; and, after their flowers are fairly set, assist a freer development by means of manure water. Show Pelargoniums that have done blooming are set outside, so as to enable them to ripen their wood, and are allowed to dry off gradually. Lilies belonging to the Japanese section are now coming beautifully into bloom, and are liberally supplied with stimulants. When repotted the pots are only filled to within two inches or so of the top, so as to leave room for top-dressings of good rich compost. Before cutting the blooms of these Lilies, the anthers are carefully removed, so as not to spoil the petals by the diffusion of the pollen. Erythras coming into bloom are assisted by means of manure water. Statives are repotted as they require that attention, but in the case of old plants, top-dressings and manure-waterings are resorted to instead of giving them a shift. Foliage plants now constitute the best feature in stoves, Alocasias, Caladiums, *Gymnostachyums*, &c., being among the most striking. All these enjoy partial shade and a sweet, humid, warm atmosphere. Allamandas, Dipladenias, Clerodendrons, and Bougainvilleas, occupy the chief positions among flowering plants, not only when trained on trellises in pots, but also on the roof, where they contrast admirably with the lovely *Cissus discolor*, a climber that thrives best when its roots have a regular and steady bottom heat. The finest plant of it perhaps ever seen was grown in a Pine stove, where it got a little bottom heat summer and winter; there it remained evergreen all the winter, and in spring pushed forth with such vigour as to require constant attention to keep it within bounds. Ornamental baskets are now being filled; *Caladium argyrites*, *Dracaenas*, *Coleus*, &c., occupy the centre, while round the sides are placed variegated *Panicum*, long trailing mosses, and other plants. Amongst Orchids, the *Disa grandiflora* is, perhaps, the finest at present, and one admirably adapted for conservatories.

Flower Garden and Shrubbery.—Privet, Hawthorn, Holly, Yew, and other hedges may now be pruned with the knife, but where they are not in conspicuous positions that operation may be done with the shears. Evergreen shrubs, and even choice Conifers, are now being pruned into shape with the knife. From *Rhododendrons*, *Magnolias*, *Azaleas*, and other similar things, the beauty of which is over, the old flowers are being removed, and, where time can be spared, the seed-pods also are picked off. Flower beds are now making satisfactory progress. In some cases even annuals have to be kept within bounds, so rapidly are they growing, and where the bedding plants cover the ground, the annuals are removed to make room for them. *Alternantheras* are growing as freely this season as we ever remember to have seen them, considering that it was almost the end of June before they were planted out. In order to guard against failure, a reserve stock of all bedding plants is kept to fill up blanks. Should they not be required for that purpose they will make good plants for yielding cuttings next spring. Herbaceous plants that have done blooming are partially cut back, but not so much as to render them unsightly. All the finer kinds of herbaceous and alpine plants have the soil around them mulched. Around the base of Rose trees are formed little basins, which, in some cases, are filled with well-decomposed litter; their real purpose, however, is to retain water, and occasionally liquid manure.

Indoor Fruit Department.—Succession Pine plants which have filled their pots with roots are being shifted. Suckers and crowns where required are potted and plunged in front of growing plants. To winter-fruited kinds, such as the Jamaica, brisk bottom-heat is kept up, and they are syringed two or three times a week. Vines that have yielded their crops, now and then receive a good syringing. To ripe grapes a free circulation of air is kept up, and

to those colouring, in addition to a little air night and day, a little fire-heat is given. To pot vines for next year's crop, light, air, and water are freely administered. Fig trees, in many cases, are now bearing their second crop. In Melon pits, in which the fruit is nearly ripe, a thorough watering is given, so as not to necessitate another until the fruit has been cut. Pinching, thinning fruit, syringing, &c., are alike applicable to Melons and Cucumbers. Beds for Mushrooms are being formed for autumn and winter bearing. They are covered with straw, and a moist atmosphere is maintained by means of sprinkling floors and similar surfaces.

Hardy Fruit and Kitchen Garden.—Last Saturday's storm has done good in the way of keeping down insect pests; nevertheless, wall trees are still gone over, and well washed by means of the garden engine. Now that the proper amount of wood can be selected for next year's crop, superfluous growths are removed, and such young shoots as are retained are laid in in such a manner as not to shade the fruit. Young shoots of Figs are loosened from the wall, and Cherries and bush fruits are netted to keep them from birds. Weeds are now growing marvellously, and not only is the hoe useful in their destruction, but in keeping the soil open; and those crops that have been well attended to in this respect have made considerable progress in advance of those that have had no such attention. Of Peas, another late sowing may be made of the tall kinds, such as Veitch's Perfection. Of Cabbages, some are being planted out for colworts, and they also furnish good heads throughout the winter. Broccoli is planted out in good firm ground, but not too rich, as that would tend to make them so luxuriant that they would not stand the winter well. An intermediate crop of Celery is planted out. The main crop of Endive is sown on a cool situation; a few of the earlier sowings are planted out. Lettuces are sown in a cool shady place, as are also Radishes, Turnips, &c. Small Salads are sown often and in small quantities. A few early Carrots are sown for drawing young. Celery for succession is being planted. Gourds and Vegetable Marrows have the ground about them mulched with litter; the shoots are pegged down, in order to encourage them to root at the joints.

NURSERIES.

Indoor Department.—Hard-wooded plants from autumn-struck cuttings, are now being potted off; also grafted Conifers, &c., which are placed for a time, until they get established, in gentle heat, and well shaded. In cool houses, Japanese Maples are being layered by plunging the pot containing the stock in tan or cocoa-nut fibre and pegging down all the branches, which are cut a little at such joints as are inserted in the material prepared for their reception; they are likewise increased by means of inarching. Clematises are also being layered under glass, and the finer kinds, or those that require to be increased quickly, are propagated by means of cuttings; such cuttings as are rooted are potted on, and placed under hand-lights in the propagating pit and well shaded for a time. They soon start into growth, and as they advance are staked. Primulas from seed are pricked off into pans, and those from cuttings are being repotted. Begonias, such as *intermedia*, *Chelsonii*, and *Boliviensis*, are being rapidly increased by means of cuttings struck in heat; the large-leaved kinds that were struck earlier in the season, and which have now formed little crowns from several centres in the leaves, are potted off singly into thumb pots. *Torenia* are being increased from cuttings, and rooted ones potted off. Young Allamandas, *Bougainvilleas*, &c., are also shifted as is necessary. Young plants of *Aristolochias* and *Dipladenias*, if likely to become pot-bound, get another shift, and great care is taken to prevent their shoots from getting entangled or broken. *Hæmadietylon nutans*, a handsome-leaved stove climber, is equally well cared for. They enjoy a warm humid atmosphere. Young plants of *Pentas carnea* are shifted frequently in order to get them to form nice specimens; the flower spikes are frequently removed for the purpose of throwing increased vigour into the plants, and also in order to keep them free from mealy-bug, which too frequently gets established amongst the flowers. Young *Humeas* for next year's decoration are repotted into four-inch pots, and kept near the glass in gentle heat or in cool houses; the last sowing is still in the seed-pan, or are being pricked off. *Yuccas* are being increased by taking off young shoots, and inserting them singly in pots placed in a cold frame, well shaded for a time. Young *Azaleas*, that were not repotted this season, are now being gone over, and top-dressed with good peat and sand. Specimen Heaths, and other Cape and New Holland plants not done flowering, are kept in cool houses and well aired. Young plants, and also large specimens, the flowering period of which is past, are set on beds of ashes out of doors, and diligently attended to with water. Besides watering the plants, the whole of the beds on which they are placed are well saturated every dry day.

Out-door Department.—Chrysanthemums are being repotted and placed outside. Passion-flowers in six-inch pots are securely

fastened to their stakes, and plunged outside in a well-sheltered border. Sollyas, Desmodiums, Hardenbergias, Eecremocarpus, Lophospermums, and many other greenhouse climbers are also plunged outside. Besides the climbing plants that are turned out to mature their wood, such subjects as Cytisus, Boronias, Eriostemons, Banksias, Daphnes, Prunses and many others, are also set out of doors. Pot Roses that throughout the spring and early summer produced flowers are now being transferred from the houses they were grown in, and plunged in beds in the open air; the surface of the pots, however, is not covered, but left exposed, so that water may be conveniently applied. In addition to such Clematises as are layered indoors, those that are growing in outdoor beds are also being layered in pots plunged a foot or so from the stock. The layers are slit up a little at the joints, pegged into the pots, and covered over with a little mould. Pinks are being increased from cuttings inserted under hand-lights at the foot of shady walls, in prepared borders which are covered on the surface with a thin layer of silver sand. Any hard-wooded greenhouse plants from autumn-struck cuttings, or Conifers not yet potted off, are kept freely exposed in cold frames. Rhododendrons, in this year's seed-pans, are placed outside, at the back of frames, so that they may receive a little protection from the sashes that are drawn down over them when the frames are open, and at the same time get a free circulation of air. The budding of Roses has begun in several places, and the stocks are everywhere being prepared for operating on. In the fruit department training is now the most important feature. Young Fig trees planted along the foot of walls, are not yet tied in to the walls; the young wood is permitted to reach a sixth joint, but not more than that. Sweet Peas for seed have been well staked, and those having a tendency to fall are tied up with string or matting. Onions and Leeks for the same purpose are just coming into bloom, and along the drills stakes are placed at intervals of from twelve to sixteen feet; to these stakes are attached cords, which run along both sides of the plants, and assist in keeping them upright.

MARKET GARDENS.

Crops now ready for market consist chiefly of Cucumbers, Vegetable Marrows, Peas, Potatoes, Lettuces, Globe Artichokes, Cabbages, Cauliflowers, Carrots, and Beet, &c. The Asparagus season being now over, the plants are allowed to mature their shoots, which they do not produce in too great abundance, nor are the plants so near one another as to be injurious to other crops grown on the same ridges. Besides Lettuces and French Beans, there are also grown on these ridges, Beet and Nasturtiums, the latter of which produce an abundance of cut flowers for market. Cucumbers in frames are duly attended to in the way of pinching and removing any decaying leaves that may be on them and regulating the fruit. Some of the growers complain of a rather inferior yield of this fruit this season. Vegetable Marrows are growing rapidly, and bearing abundantly; another plantation of them has just been made. When practicable the surface of the ground is mulched with litter; especially is this the case with Custard Marrows, which are planted in beds eight feet apart, with a line of Lettuces or French Beans between the beds. To Tomatoes, planted in lines three feet apart, a little earth is drawn, so as to form as it were the ground into broad shallow beds, a plan which economises the watering. Beds are being formed for celery by thoroughly working the soil and making them four feet wide with a fifteen-inch alley between them sunk a few inches. The Celery will be planted in the alleys, and Lettuces or Coleworts on the beds. Walls not covered by fruit trees have stakes stuck up against them, on which Scarlet Runners are trained. Onion crops are being gone over a third time and cleaned; their growth is strong, and they do not seem to have suffered in the least from the tramplings received in former cleanings. Beet and other root crops from early sowings exhibit a tendency to run to seed. When fruit trees are thickly planted, and the under crops removed, a mulching of litter is spread over the ground, which not only prevents the soil from becoming too dry, but also preserves the fruit from injury should it happen to fall.

MARKET GARDENING.

BY H. EVERSHED.

(Continued from p. 14.)

THE BEDFORDSHIRE DISTRICT.

THE Bedfordshire district lies in Biggleswade, Sandy, and adjoining parishes. The soil is a sandy or gravelly loam, of excellent quality when not too light or thin, resting on sharp gravel, sand, or sandstone rock. The river Ivel, formerly navigable, runs through the district, joining the Ouse at Tempsford. Water is generally found at

a depth of 16 feet. In order to shelter a level tract, rows of lofty elms, trimmed into excessive ugliness, are allowed to disfigure the country in every direction. The same object might perhaps be attained, with agreement among proprietors, by the planting of fast-growing timber at salient points, to break the currents of wind, and the neighbourhood might be ornamented, as well as protected, by such means, without injury to the crops. The district is not now particularly well situated for market-gardening; certain industries, however, cling to particular localities. Bedfordshire has long been famous, and a favourable soil, the railway, artificial manures, and skill together, have preserved its prestige, so that the labourers who come into the metropolitan district from all quarters in the hoing season prefer to be called Bedfordshire hoers, and to enjoy the credit of having come from a noted district. There are many garden-farmers occupying less than 10 acres, others occupy from 10 to 50 acres, and a few even more, and some are owners as well as occupiers. Spade labour is not resorted to, and the small farmers are accustomed to hire teams of horses when they require them. The crops are kept remarkably clean, and every kind of work is well done; for the employer, instead of sending his men to their labour, is in the habit of taking them to it and keeping them at it, his occupation being so small. Garden-farming is entirely dependent, here as elsewhere, on a supply of manure from outside the farm, consequently, at a distance of more than two miles from the railway station, gardening merges rapidly into farming; and it may be added, that when farmers have been tempted by the large gross returns to combine the cultivation of vegetables with their ordinary business, they have not usually been successful. The business of market-gardening is one in which both the master and his man should have served an apprenticeship.

The crops grown include a considerable breadth of corn, turnip, kohlrabi, and onion-seeds, and a few carrots and parsnips. Scarcely any peas are grown, and none of the "fancy crops," such as flowers and culinary herbs. The main crops are potatoes and onions, both for pickling and for "lofting," *i.e.* storing in airy lofts constructed for the purpose, with louvre boards for ventilation. A large portion of the produce is sent to the manufacturing districts. It is common to sell largely to the dealers or agents who visit Bedfordshire after the middle of June, for the purpose of buying the growing crops of potatoes, which are lifted and marketed under their direction, during the following three months, before the Scotch supply has commenced. This intervention of middle-men seems to be practically necessary, in order to regulate and distribute the daily supply of vegetables at the various distant markets. The succession of crops is not regular. It is observed that turnip-seed is a good, and potatoes a bad preparation for wheat, and that onions ought not to be taken from the same ground oftener than once in five years. A common rotation is: 1, onions; 2, turnip-seed, or potatoes; 3, wheat; followed by such crops as onion-seed (after potatoes), cucumbers, carrots, or parsnips. The most important crop is onions, which receive enormous dressings of manure, and sometimes yield a handsome return. The method of cultivation is the same as at Barking—one ploughing, six inches in depth, and the manure harrowed in with the seed—50 tons of dung per acre are sometimes applied, costing 8s. per ton at the railway, and 10s. when spread in the field. Small dressings of guano are occasionally used, but in the case of onions intended for "lofting," forcing manures must be applied cautiously, as they induce a luxuriant growth; and as bulbs which have been grown too rapidly do not keep satisfactorily, the grower loses the chance of selling his crop at £11 per ton in March! The cost of hoing is £5 for the season.

Turnip-seed or potatoes follow onions, with a dressing of guano for the former and of soot for the latter. Turnip-seed is grown for seedsmen who supply the farmer with stock seed, which is drilled at 24 inches apart, or the plants are transplanted from a seed-bed in November. One ploughing suffices for this crop. The land is ploughed in autumn for potatoes and again in spring, and the sets are planted with a dibble at the second ploughing. In the case of early potatoes a wide furrow of 9 inches or 10 inches is given, and the sets are placed in alternate furrows. Late potatoes are planted in every third furrow of 8 inches or 9 inches. A few other particulars may be briefly noticed. Early potatoes (which are not earthed), and scarlet runners are planted in alternate rows, the latter occupying the whole space between the rows (3 feet or 3½ feet) after the removal of the potatoes. A large breadth of cucumbers is grown. They are manured with perhaps 40 tons of dung per acre, planted thickly in rows, sheltered at 6 feet intervals by rows of rye or onion seed. Some growers sow many acres with this crop. Onion seed is also grown at 2-foot intervals, and is sometimes supported by stakes and string, but more generally by earthing up. The lowest day-wages of the district are 12s. a week; gardeners, however, require skilled labour, and pay higher rates. A great deal of work is done by task.

GENERAL REMARKS.

The preparation of the land for onions indicates that they prefer a solid surface. In the Essex district a ploughing is given before Christmas, a large quantity of short dung is spread on the land during frost, and is well knocked with a fork; it is afterwards harrowed in with the seed. If dung be ploughed in, and especially if it be covered deeply, it is observed that the plant does not get hold of it until late in the season, and a rampant habit is induced at the end of June, when the onion ought to be bulbing. The consequences of ploughing in dung would perhaps be less injurious on old garden ground, which is full of manure. Lisbon onions for salads are sown in August or early in September. Pickling-onions require the same cultivation and excessive manuring. They are sown very thickly, and are bleached by casting mould over them a short time before the crop is secured. The process of brining and skinning the crop for one large grower, employs about 400 women working in sheds. Dung, which is usually placed in large heaps five feet high and frequently ten yards wide, is twice turned for onions.

Peas are not profitable in the field-garden district. An occasional piece of early peas is sown in November, to be followed by some such crop as broccoli, which may be planted as soon as the peas are off. After hoeing, the peas are moulded up and the haulm is laid to check over-luxuriance.

Broccoli and cauliflowers are largely grown on the strong, deep-fruit-bearing soil of Enfield, a spot which is famous for the tribe, and has given a name to one of the varieties of cabbage. The cultivation of cauliflowers and of Walcheren broccoli has been noticed in connection with a garden in Bermondsey. The latter are usually planted after potatoes or cabbages at the end of June or early in July, and are cut from September to December. Market gardeners also provide a crop of broccoli to cut early in spring, sowing the sprouted and winter-white and other kinds to plant early in September after potatoes, &c. A heavy coat of dung is turned in with a deep furrow, on deep soil, by three horses, or dug in when the occupation is small. The earliest are sold in time to sow carrots or onions. Other varieties follow during the spring and summer.

Without plenty of manure and garden cultivation lettuces run to seed quickly. Hammersmith has given a name to one variety, and they are confined in great measure to neighbourhoods where the gardens are small. The Brown Cos is sown in November for early use; this and the white and better, but less hardy varieties, are sown in succession from February till June. The chief demand in London is at the end of May, and during June and July. Early sowings are made in seed-beds, later sowings may be made in drills without transplanting.

With respect to the weight of crops, which is the chief point of agricultural interest, garden crops are generally removed before they are mature, and they are planted thickly with that object. It is not the weight, but the number of bunches, that yields a large return. Prices vary so much that no precise estimates on the subject can be given, although one of my informants lent me his books containing exact accounts of monthly sales for several years. I can report a sale of early potatoes (3 tons per acre) at £11 per ton, on a Saturday in the third week in June; on the Monday the price was £9 per ton, and it soon fell one half. Cabbages when very plentiful are sometimes sold at 4d. a dozen, they ought to fetch 9d.; and it is very satisfactory to the grower when they sell at 1s. a dozen. Three hundred dozen bunches of carrots per acre, including "chumps" or rough carrots, sold to stable keepers, are a very large crop; 2s. 6d. per dozen is a satisfactory price. This year carrots are considered to sell well at 3s. A bunch contains from 50 carrots, early in the season, to 25 when they are larger, 20 tons of Belgian carrots, is considered a good crop; 40s. a ton is a common price at the stables in London. A crop of parsnips generally weighs considerably more; the price of the finest roots varies from 1s. to 1s. 6d. per score of 22. A good crop of collards is 200 dozen bunches. It varies between 50 and 350 dozen, and the smaller crop may pay best, reducing the land but little, and selling perhaps at a high price, with comparatively small deductions for the cost of labour and marketing. One hundred and fifty bushels of peas is a large crop, and £15 on the ground is a very great price, which is sometimes paid by dealers for a crop that would yield 8 quarters of threshed peas; 2s. 6d. or 3s. per bushel are common prices in Covent Garden, up to 8s. for the first early peas, or for "blues" when they come first to market, "whites" being then worth but little. A crop of onions, I believe, weighs about half as much as a crop of swedes in the Eastern Counties, where 20 tons of swedes are a great crop, and from 10 to 15 tons are common crops; price from 5s. to 9s. per hundredweight. Prices are affected by a variety of circumstances which cannot be foreseen. A blight in the early potatoes would raise the price of carrots and other competitive vegetables. Cabbages were selling this year at 1s. a dozen on June 14th, because there were few peas or

potatoes at market. Each gardening district has its inuings, which terminates suddenly; for example, any district which is earlier than another has possession of the market so long as the advantage lasts. During a fortnight last spring immense quantities of cabbages were sent from Essex to the great manufacturing towns in the north.

Lisbon sends the earliest potatoes to London, the French coast and the Scilly Islands follow, then Jersey, Guernsey, Cornwall, and Holland; and by the middle of June, these distant but early districts are driven out of the market, by the arrival of supplies from Essex, &c. Red cabbages have been sold at 160s. per ton early in the season, and at 25s. per ton a fortnight afterwards; or at from 1s. to 4s. per dozen. Lesser movements in the trade are governed by the supply of labour and other circumstances. In a parish where a great many French beans were grown, the erection of a factory absorbed the pickers, and beans were given up, as well as broccoli, which had previously been planted between the rows of beans on the solid ground, which suits them. The garden farmers send their own men with the waggons to sell their goods in open market, instead of consigning them to salesmen. The cost of carrying goods to market, of baskets, packing, and market dues is estimated at 50s. an acre on large garden farms.

The customary prices of Task Work in the Essex district (day wages 15s. a week) are:—Hoeing per acre—cabbages at 2 feet by 15 inches, 1st and 2nd time, 5s. each; 3rd, 4s. 6d.; potatoes 3s. or 4s., and afterwards chopped over by the day previous to earthing; carrots, broadcast, £3; onions, £4. Lifting early potatoes by fork, sorted into firsts, seconds, and chafs, placed in sieves of 56 pounds, or baskets of 1 hundredweight, covered with haulm and weighed in the field, 8s. per ton for a crop of 3 tons. Picking peas, from 4d. to 6d. per bushel. Pulling, bunching, washing, and loading early carrots, 7s. per 20 dozen bunches. A sieve is a basket holding 56 pounds of potatoes, or 5 pecks of peas when heaped, wholesale measures being liberal. A small sieve such as is used for French beans and fruit, holds about half a sieve. A prickle is a conical basket, equal to a half sieve. A punnet is a round open basket holding 10 or 12 apricots, made of the same light material as the conical strawberry-pottle.

SOCIETIES, EXHIBITIONS, &c.

ROYAL BOTANIC GARDENS, REGENT'S PARK.

(JUNE 10TH AND 11TH).

THIS, the last exhibition of the season, was well supported in the way of stove and greenhouse plants, conspicuous among which were *Allamandas*, *Ixoras*, *Heaths*, among the latter being a fine specimen of *Erica Parmenteri rosea*, densely grown and finely bloomed; *Phanocoma prolifera* *Barneisii*, *Statice profusa*, *Dipladenias*, *Vincas*, *Anthurium Scherzerianum*, and a lovely specimen of *Kalosanthes Phoenix* (from Mr. Ward), which was fully two feet in diameter, dwarf, compact, and a complete mass of brilliant flowers. Fine foliated plants consisted of large specimens of *Crotons*, *Dracenas*, *Palms*, variegated *Yuccas*, and some good plants of *New Zealand Flax*. Among *Caladiums* were some large, well-grown plants, so neatly staked that nothing but the foliage was visible. Prominent amongst them was a fine specimen of *C. argyrites*, which, for a dwarf-growing kind, was in an unusually flourishing condition. Of Ferns there was a grand display; among them were some fine plants of *Pteris scaberula*, *Adiantum Farleyense*, *A. formosum*, *Davallia bullata*, and some of the taller growing kinds, such as *Cyathea*, *Dicksonias*, *Angiopteris*, &c. Hardy Ferns, however, constituted the most interesting and numerous group; besides those put up for competition, a large group, staged for exhibition only, by Messrs. Ivery, of Dorking, consisted of some of the finest and most graceful of Ferns. Conspicuous among them were *Adiantum Capillus-veneris*, crested and fringed *Scelopendriums*, a fine plant of *Cystopteris fragilis*, large pans of *Polypodium Dryopteris*, and many fine forms of *Lady Fern*, especially one called *Athyrium Filix femina pulcherrima*, a most graceful plant. Orchids were sparingly shown, but such as were produced were in every way excellent. From Mr. B. S. Williams came some fine plants of *Aërides Larpentæ*, *A. odoratum majus*, *Mitella spectabilis*, a very fine specimen of *Thunia alba*, a well flowered plant of *Barkeria spectabilis*, and an excellent example of *Cypripedium Stonei*. In the amateurs' class were also finely flowered plants, particularly *Phalenopsis grandiflora*, *Odontoglossum Bluntii*, and a fine specimen of *O. Uro-Skinneri*. The most attractive Orchid in the show was, however, perhaps the lovely *Masdevallia Harryana*, in Messrs. Veitch's collection. Of *Fuchsias* several groups of six were contributed, but, although fairly grown, among them there was nothing remarkable, the kinds being confined to such sorts as all of us have often seen before. *Pelargoniums* included zonal, tricolor, and golden bronze kinds. The zonals grown as specimens on the flat system were very fine, some of them being fully three feet through. The finest specimens were *Virgo Marie*, a pure white; *Rose Rendatler*, a pink; and among scarlets, *Pioneer*, *Dr. Lindley*, *Cham*, and *Lord Derby*. Tricolors comprised the commoner kinds, but in this class we seldom get large specimens. The golden bronzes of Messrs. Downie, Laird, & Laing were most luxuriant; they

consisted wholly of fine new kinds. Four Clematides in small tubs, well furnished both with leaves and flowers, were contributed by Messrs. Jackman. They were named Alexandra, rubella, Thomas Moore, and Mrs. James Bateman, all purplish blue sorts. Balsams were shown by Mr. Puttick, Park Road, Acton; they were dwarf, bushy, and well flowered, the blossoms being as double as those of a Camellia. Hardy herbaceous plants in pots were well represented by Mr. Parker, of Tooting, and by Mr. Ware, of Tottenham. Mr. Parker's collection consisted of large well-bloomed specimens of *Coreopsis tenuifolia*, and *C. lanceolata*; *Delphinium Hendersonii*, a lovely deep blue; *Santolina lavenderifolia*, *Eriogonum Fraseri*, a fine yellow; *Betonica hirsuta*, and *B. stricta*, the double pink flowered *Calystegia pubescens*, one or two *Campanulas*, and others.

Among cut blooms of herbaceous plants from Mr. Ware were some fine flowers of the showy *Gaillardia grandiflora*, spikes of the double-flowered *Spirea Ulmaria*, a decided improvement on the single sort; the beautiful *Alstroemeria lutea*, the large-flowered *Crimum-like Amaryllis longiflora* alba, some spikes of the double-flowered blue *Delphinium Mooreanum*, a pretty and useful border plant. Besides cut blooms, Mr. Ware also furnished a group of alpine plants in pots, and an admirable display of *Pentstemons* with large and showy flowers; also a collection of *Phloxes*. A good collection of the last was also furnished by Messrs. Downie, Laird, & Laing. The alpine collection included white and blue varieties of the *Campanula turbinata*, a large open-flowered kind, and very dwarf; *Primula auriculata*, *Selleria radicans*, and the rosy-flowered *Lythrum flexuosum*, a valuable acquisition to our stock of alpine, being of a somewhat prostrate habit, and a very free flowerer.

Miscellaneous collections of plants comprised some fine groups. Messrs. Veitch's exhibition itself was worth going a long journey to see. It contained among other things, *Lomaria zamiaefolia*, a strong-growing beautiful fern, *Adiantum peruvianum*, a kind with large pinnae of graceful form; *A. amabile*, a small pinnate kind, each leaflet being nicely fringed, also a very beautiful kind, *Platyterium alcoicorne majus*, an improvement on the old Elk's-horn; some good crested silver and golden *Gymnogrammas*, and a pretty *Selaginella* called *S. japonica*. There were, moreover, *Aralia Veitchii*, one of the finest of *Aralias*; the beautiful yellow-flowered coral-like *Tillandsia Zahnii*, several fine *Dieffenbachias*, such as *D. Bausii*, and *D. braziliensis*, the latter a finely spotted kind; and some beautiful *Dracaenas*. Of *Crotons* we noticed a handsome kind called *Youngii*, the old leaves of which, like those of *C. undulatum*, assume a red and green colour, and the young ones, the first season, a yellow and green hue. Among flowering plants in this collection, the most striking was *Lasiandra macrantha floribunda*, the blooms of which are very large, and of a deep violet colour. In Mr. B. S. Williams's collection were some fine varieties of *Lilium auratum*; a good plant of *Phormium Colensoi*, one of the finest of the New Zealand Flaxes; some good plants of *Pandanus Veitchii*, and a good pan of *Sarracenia purpurea*. Messrs. E. G. Henderson & Sons had a nicely arranged group of bedding plants, for which they received a prize. Messrs. Lee, Hammersmith, Mr. Morse, of Epsom, and also Mr. Bester, Pine-Apple Nursery, exhibited good collections of stove and greenhouse plants arranged for effect.

Amongst cut-flowers the greatest favourites were the *Roses*, the blooms of which were exceedingly fresh and beautiful. Two new *Roses* furnished by Messrs. Paul & Son were very fine; viz., a Tea called *Chestnut Hybrid*, and a Hybrid Perpetual named *S. Reynolds Hole*, which is one of the finest dark red velvety *Roses* in cultivation. A stand of *Tuberose*s furnished by Mr. R. Webb, of Calcut, were so very fine as to make us regret that this sweet-scented flower is not more frequently seen at our exhibitions. *Picotees* and *Carnations*, in the form of cut blooms were exhibited in fine condition by Mr. C. Turner and others.

Fruit was all that could be desired. *Pine-Apples* were numerous and excellent. They consisted chiefly of *Queens* and *Providences*, but there were also examples of *Black Prince*, and a fine fruit of *Charlotte Rothschild*, which weighed seven pounds eight ounces. One of the *Providences* also weighed ten pounds three ounces. There were some pot Vines bearing heavy crops of fruit, each having as many as ten bunches; those from Mr. Cole being wonderfully good, plump, and well coloured. The most wonderful examples of *Grape* culture in the exhibition were, however, two pots produced by Messrs. Lane, of Berkhamstead. On each of these there were no fewer than twenty clusters, all in excellent condition, the berries, as well as the bunches, being large and fine. Of cut *Grapes*, both white and black, there was no scarcity, and their quality, in most cases, was of a high order. White kinds consisted of *Buckland Sweetwater* and *Muscat of Alexandria*; the black sorts of *Black Hamburg* and *Black Alicante*. Several *Melons* were exhibited, but they comprised nothing very remarkable either in point of quality or kind. Only two *Cucumbers* were staged, called *Wonder of the World*, and said to be a hybrid between *Highgate Rival* and *Telegraph*. *Peaches* and *Nectarines* were pretty good, especially those which obtained prizes. The first prize *Peaches* consisted of *Noblesse* and *Padley's Early*; other dishes comprised *Royal George*, *Bellegarde*, *Téton de Venus*, *Violet Hative*, *Admirable*, and *Incomparable*. Among *Nectarines* were *Hunt's Tawny*, *Elruge*, *Roman*, *Pitmaston Orange*, and *Newington*. *Cherries* were not well represented, only a few dishes being exhibited, but these were nice fresh-looking fruit; the kinds were *Bigarreau*, *May Duke*, *Elton*, and *Downton*. Of Figs only a dish or two amongst collections of fruit could be seen. *Norfolk Bearer Apples* from E. Clark, *Holmbush House*, *Horsham*, *Sussex*, were much admired, on account of the admirable manner in which they had been preserved. *Strawberries*, upon the whole, were as good as we have seen them; the kinds were *Elton Pine*, *Princess Helena*, *Comte de Paris*, *British Queen*, *President*, *Lucas*, *Vicomtesse Héricart de Thury*, and

Sir C. Napier. Of bush fruits, such as *Currants*, *Gooseberries*, and *Raspberries*, there were only a few, the *Raspberries* being rather inferior in quality. Perhaps the most attractive fruit on the tables was a dish of what are called *Water Lemons*, or fruit of *Passiflora laurifolia*; they were of a deep amber colour, and about the size of common *Nectarines*. They were accompanied by some of their leaves, which are thick and glossy, not unlike those of the common *Laurel*.

The dinner-table decorations were very interesting. It is evident that great improvements have been effected in this direction by the many exhibitions that have been held during the past few years. The exhibitors, almost without exception, manifested good taste in their arrangements; so much so, that one regretted more prizes than the usual three were not given. The contrast between the groups shown on this occasion, and the wonderful ones that were so often seen eight or nine years ago was marked indeed. The best group in the exhibition, that shown by Mr. Bester, was composed almost wholly of hardy plants, grasses, *Spirea ariæfolia*, *Roses*, *Forget-me-Nots*, &c., all plants within everybody's reach. Some of the groups shown were greatly disfigured by the use of branched glasses. In no case in which these were employed was a really good effect presented. They are quite wrong in design, and even such accomplished artists as Miss Hassard and Miss Blair failed to make them effective. The mixed arrangements of fruit and flowers were quite puerile, with one exception, to which a second prize was awarded. Bouquets of all kinds were very poor indeed.

First-class certificates were awarded to *Picotée Prince of Wales*, P. Mrs. Allerof, and a self-coloured *Carnation*, *Prince Arthur*, from Mr. C. Turner, Slough; to seedling *Picotées* *Miss Norman* and *Charles Williams*, from Mr. Norman, 98, Crescent Road, Plumstead; also to Hybrid Perpetual *Rose S. Reynolds Hole*, and *Tea Rose Cheshunt Hybrid*, from Messrs. Paul & Son. First-class certificates were also awarded to *Anætochilus Ortgiesii*, from Messrs. Carter & Co.; to *Lythrum flexuosum*, and to a species of *Artemisia*, from Mr. T. S. Ware; to *Cureuma petiolata*, from Mr. R. Parker; to a *Hymenophyllum*, from Colonel C. J. Cox, Fordwick, Kent; to *Dipladenia amœna*, and *Gymnogramma grandiceps*, from Mr. B. S. Williams; to *Erica opulenta* and *splendens coronata*, from Messrs. W. Rollisson & Son; to *Selaginella japonica*, *Croton Youngii*, *Adiantum peruvianum*, *Platyterium alcoicorne majus*, *Dieffenbachia braziliensis*, *Echeveria scaphylla*, *Tillandsia Zahnii*, *Leptopteris Wilkenskiana*, *Masdevallia Harryana*, and *Lasiandra macrantha floribunda*, all from Messrs. Veitch and Son; and certificates of merit to a specimen *Fuchsia*, from Mr. G. Wheeler; and to an *Early Prolific Marrow Pea*, from Mr. Evershed, of Godalming.

OBITUARY.

WE have to announce with regret the death of Mr. Wyuess, who has been for very many years gardeuer to her Majesty at Buckingham Palace. He was a quiet, kindly-disposed man, who had many friends, and therefore his loss will be widely felt. He was an enthusiastic florist, and raised in his time several new kinds of *Verbenas* and *Dahlias*. Some of his seedling *Dahlias*, indeed, still rank among our best show flowers of that kind.

COVENT GARDEN MARKET.—July 12th.

Flowers.—Japan *Lilies*, grown in six or eight inch pots, are now plentiful. There are also several small specimens of the beautiful *Amarantus sabicifolius*, and of the sweet-scented double *Gardenias*. Cut flowers consist of many fine spikes of *Orchids*, blooms of *Stephanotis*, *Pinks*, *Dianthus*, *Centaureas*, *Irises*, *Sweet Peas*, *Ixias*, *Roses*, and others.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

RECOLLECTIONS OF JOHN CLAUDIUS LOUDON.

BY NOEL HUMPHREYS.

(Continued from page 2.)

In the year 1806 Mr. Loudon was still actively engaged in his favourite occupation of landscape gardening, in various parts of the country, and earning a well-deserved golden harvest as the reward of his persevering labours. In that year he was also employed in a very extensive land reclamation scheme; that portion of his first work which he devoted to "Gaining and Embanking Land from Rivers and the Sea," having attracted the attention of a great Welsh landowner, Mr. W. A. Madox, who had conceived the idea of reclaiming a large tract of land on the coast of Carnarvonshire. Young Loudon was invited to Tremadoc by the spirited projector; and during the progress of the works, which created general interest, the seat of Mr. Madox became the rendezvous of many of our celebrities in science and art; and the wild but somewhat dreary scenery among the Welsh mountains was often enlivened by night, as Mr. Loudon used to tell, by the dazzling glitter of thousands of lights in and around the residence of the great land reclaimer at Tremadoc; while the ravishing notes of the famous Mrs. Billington, whose noble portrait as St. Cecilia, by Reynolds, is one of the great portrait painter's master-pieces, supplied the place of the absent nightingale amidst the solitude of those Welsh valleys. On moonlight nights, as he used to relate, the peak of Snowdon might be seen terminating the vista of the Vale of Tremadoc, and looking gaunt, dim, and grey, as one of the mysterious mountains that Ossian made the spirit home of his shadowy warriors of the mist. The young horticulturist was much dazzled by this visit, and wonder-struck at the lavish profusion of the choicest wines, that flowed like water at the evening entertainments; and he was amazed, too, at the perfect roar of boisterous wit, of the highest class, that generally accompanied the costly eating and drinking. That was the era of clever talkers and great wits, whose places have never yet been effectually refilled.

This phase of the young Scotchman's career was destined to a somewhat melancholy conclusion. Returning from Tremadoc outside the night mail, he became drenched to the skin with soaking and continuous rain, and, omitting to take prudent precautions after the journey, he was seized with rheumatic fever in its severest form, the remains of which finally settled in his left knee, and the medical man he submitted his case to being injudicious in his treatment, the joint became permanently stiffened, which was naturally a source of great annoyance to him, not only at the time, but during the whole course of his life, as it greatly impeded his exertions in the active pursuit of his profession, and also caused a limp in walking, which at the age at which the accident occurred to him severely wounded that personal vanity which is a very general characteristic of youth, and Loudon was then in his prime, and blessed not only with a good constitution but a fair share of good looks. There was also another regret that pursued him through life, which was, that although a large tract of valuable land was eventually reclaimed from the sea, and although fertile meadows were made to appear where the barren wash of the shallow, far-spreading salt tide had so long held its useless, brawling reign, yet, so great had been the cost of the reclamation that, next to ruin, instead of the realization of a vast fortune, was the sorry reward of the spirited projector, and a sore disappointment to his conscientious advisers.

The stiffened knee became, incidentally, the cause of events

which materially altered the after part of his career. While suffering from the severe pain consequent on the diseased joint, he determined to seek for rest and retirement for a while in some quiet country place, and with this view he took lodgings at a farmhouse at Pinner—the Pinner-cum-Harrow of ecclesiastical arrangements, the Vicar of Harrow having the gift of the perpetual curacy of Pinner, which is only four miles distant from the historical Harrow-on-the-Hill.

While at Pinner, he soon became convinced that he could not remain entirely idle, and he seized that opportunity of inquiring into the actual state of English farming, which he found much in arrear of the systems pursued in Scotland. He therefore set himself to work, to investigate the best methods of obtaining better and more profitable crops in England. He was, in fact, the true pioneer of improvements in English agriculture, long before the Mechi's and other great improvers eventually followed in his track. He also devoted himself with great energy at that time to landscape painting in oil; and, considering the short period during which he applied himself to that art, his progress was very satisfactory, several of his works of that class, produced at Pinner, being exhibited by him at the Royal Academy, when the annual shows of the English school of art were held at Somerset House. During the same period, too, regretting his former neglect of the acquisition of languages, he engaged a professor of German, with whom he worked perseveringly during the whole of his stay at Pinner. Having been very successful, by dint of untiring assiduity, he succeeded in paying his expenses, as he had formerly done those of his French master, by the sale of a pamphlet, which he translated from the German as an exercise, the work being sold to Mr. Cadell for £15. We also learn from his journal that he took lessons in Greek and Hebrew at this time, with a view to the tracing out the origin of the names of all the plants described by ancient classical writers. But notwithstanding all this mental activity, he still believed that he was not doing enough, and we find him, in his journal, bitterly reproaching himself for his idleness, in such passages as the following:—"How have I neglected the important task of improving myself! How much I have seen! What new ideas have developed themselves before me, and what different views of life have I acquired since I came to London, three years ago! Yet I am now twenty-three years of age—perhaps one whole third of my life having passed away, and what have I done to benefit my fellow-men?"

So convinced had he become of the radical defects of the English system of farming during his investigations at Pinner, and so anxious was he that the faults he observed should be corrected, that he wrote to his father, who thoroughly understood the practice of the Scottish system, begging of him to come to England, and take up the farm where he had been staying so long, which was then to let. The farm in question was Wood Hall, belonging to a family of the name of Leterrier, whose tenant it was soon arranged that Mr. Loudon, senior, should become, and to which, on the recommendation of his son, he removed in the year 1807.

Young Loudon continued to reside there with his father, and in the following year, 1808, he wrote a pamphlet, entitled "An Immediate and Effective Mode of Raising the Rental of the Landed Property of England, and Rendering Great Britain Independent of other Nations for a Supply of Bread Corn. By a Scotch Farmer, now Farming in Middlesex." This pamphlet created a great sensation in the agricultural world, and probably led to some of the great Enclosure Acts which were passed soon after that period. Hundreds of acres round Pinner were at that time open common, entirely unproductive, though within thirteen miles of London. I have heard an old inhabitant declare that in his youth, so great was the extent of waste common in that part of Middlesex, and extending into Herts and Berkshire, that a horseman might gallop without let or hindrance, from the foot of Harrow Hill to Berkhamstead, over wild heathland, entirely uncultivated, nearly the whole of which has since been brought into cultivation by the great Enclosure Act of the period alluded to.

Loudon was, in fact, as I have said, one of the great modern pioneers of our recent progress in agriculture as well as in horticulture, and his Pinner pamphlet made his advanced opinions on agricultural subjects very widely known. Among

many gentlemen who were attracted by the strikingly new and yet practical views of the young Scottish agriculturist, was General Stratton, the owner of a large landed estate called Tew Park, in Oxfordshire. In order to secure his services on the Oxfordshire estate, General Stratton proposed that the young author should take a portion of his landed property there at an almost nominal rent, in order to induce him to undertake the advantageous management of the rest for the proprietor, by the introduction of the Scotch system of farming, which the General felt convinced, after a careful study of young London's work, would be of the greatest benefit, not only to Oxfordshire, but to every agricultural county in England.

(To be continued.)

GARDENERS IN AMERICA.

MR. PETER HENDERSON, of Jersey city, the well-known American horticulturist, who is now on a tour of observation in this country, has requested us to warn young gardeners who contemplate emigrating to America, against going there at any season but in spring. They should, to secure employment soon, arrive there during the months of February, March, or April. Mr. Henderson informs us that he has often seen great hardships resulting from men arriving in America at seasons when it is almost impossible to obtain work there. We hope shortly to have the pleasure of publishing some remarks on this, and kindred subjects, from the pen of Mr. Henderson, who is so well qualified to speak on such matters, and in whose remarkably interesting and well-managed establishment in Jersey city, so many young British gardeners have found temporary employment.

POISONING BY MONKSHOOD.

THE *Daily Telegraph* informs us that "hardly a year comes round in which a whole family is not poisoned by the blunder of some crass gardener, who has dug up a root of the deadly monkshood, and given it to the cook as horseradish. To distinguish between the two roots would have puzzled Gerard himself." The *Daily Telegraph* is wrong; no gardener would do anything of the kind. Poisoning people with roots of monkshood may be one of the attributes of the much-sought-for individuals who look after pigs, cows, poultry, horses, &c., and whose main virtue is supposed to be their horticultural skill; but we never met with a trained gardener "crass" enough to make such a mistake. Nor is it difficult to distinguish between the two roots. The monkshood root invariably tapers somewhat like a slender carrot, only in a still more marked degree; while, as everybody knows, the horseradish never does so, but is like a smooth-running stick in outline. Nevertheless the monkshood is a most dangerous plant in a garden, and should never by any chance have a place in or near a kitchen garden, as, unfortunately, too many cases have happened in which persons, not gardeners, and totally ignorant of plants, have gathered it and used it as horseradish.

FLOODS AND CEMETERIES.

THE papers are full of the details of the great floods at Manchester and in the adjacent districts. A large portion of the surface of the country passed in travelling by the Great Northern Railway and its branches through Yorkshire is covered with sheets of water. Great damage to crops has resulted in many districts, besides those in which the floods have been so terribly disastrous. Gardens, both public and private, in the northern districts have suffered much. A most painful feature of the late floods was the uprooting of a cemetery at Manchester, which has been so fully reported in the daily papers. The cemetery question is essentially one for the landscape gardener, and this event should direct his attention to the necessity of so placing and so disposing cemeteries that danger from floods or any similar cause is rendered practically impossible. Cases of negligence or short-sightedness in this way are far too common; and it is only such

appalling cases as that at Manchester gets much talked about. Visitors to the late great Birmingham flower show might have noticed an instance in the Aston Cemetery, close to the ground where the flower show was held. There a wall and much of the earth inside it had fallen away, exposing the coffins along nearly the whole of one side of the ground. If the designers and managers of our cemeteries do not protect us from such scenes, let us hope the question may not be thought beneath the attention of the Government. To lovers of gardening the question is one of peculiar importance, inasmuch as cemeteries properly laid out and planted are, in addition to their other and higher claims to our attention, among the most beautiful of public gardens. We need only instance the Coventry Cemetery, the Dean Cemetery at Edinburgh, and the grand cemeteries in all the great cities of the eastern States of America, which are parks in extent, and flower gardens in keeping and in the beauty and abundance of their shrubs and flowers.

W. R.

MR. AYRTON AND DR. HOOKER.

A MEETING took place on Tuesday last, in Wellington Street, Covent Garden, under the presidency of Mr. Bateman, for the purpose of taking into consideration the present state of affairs at Kew. Resolutions were proposed expressing sympathy with Dr. Hooker, and a committee was formed for the purpose of placing the matter, if possible, upon such a footing that the public interests may not suffer, and that Dr. Hooker may be protected from all unnecessary interference in the performance of his duties. By direction of the committee just alluded to the following memorial was sent to Mr. Gladstone:—

To the Right Hon. W. E. GLADSTONE, M.P., First Lord of the Treasury.

"We the undersigned, being personally interested in botany and horticulture, and conscious how intimately the progress of those branches of knowledge and industry is connected with the proper administration of the Royal Gardens, Kew, and of the museums and herbaria thereto belonging, venture to call your attention to the present unsatisfactory condition of affairs as regards the management of that establishment.

"We respectfully submit that the system of making one official responsible for the conduct of what repairs may be requisite in the apparatus used for heating the houses that contain them, is likely to be in the highest degree detrimental to the public interest, while the harmonious co-operation of the officials engaged, and which is so essential in such a case, can hardly be looked for under such a system.

"We beg leave respectfully to state our opinion that the full control over all details of management, of whatever kind, should be left to the director.

"We venture to suggest that the Board of Works is not the most appropriate body to exercise supervision over such an establishment as Kew, where great scientific interests are at stake, as well as the instruction and recreation of the people.

"We would, therefore, respectfully urge upon you the expediency of placing the directorate of Kew directly under some other department of the Government. And, lastly, we would express our hope that you will be pleased to take such measures as shall in future secure that the director of a large public establishment shall, if for no other reason than the respect due to his office, be treated with fitting consideration.—Signed, on behalf of the meeting,

"JAMES BATEMAN, F.R.S., Chairman.

"MAXWELL T. MASTERS, M.D., F.R.S., Hon. Sec."

The following memorial to the Premier has also been forwarded by the Council of the Royal Horticultural Society:—

"The Council of this Society, being convinced of the admirable manner in which the Royal Gardens at Kew have been conducted for so many years by Dr. Hooker, and of the great benefits to horticulture and botany which have resulted from his highly cultivated scientific attainments, venture to hope that Mr. Gladstone may be able to take such steps as will confirm and uphold Dr. Hooker in his present appointment, and enable him to continue his labours with satisfaction to himself and advantage to the country.

"W. W. SAUNDERS, F.R.S., Chairman."

The Malva Family.—The great beauty of this family is now apparent in some of the collections of herbaceous and alpine plants around London. We allude to such plants as *Sida malvaeflora* and *incarnata*, *Malva Alcea*, *Morenii*, and the British *M. moschata* with its white variety, and the *Lavateras thuringiaca* and *unguiculata*, the latter one of the finest herbaceous plants in flower at the present time, a good specimen of which may be seen at Kew. It grows about six feet high, and has large bright rose-coloured flowers. The flowers of these are generally of a light clear rose colour, and are produced in dense masses, and the plants are hardy and vigorous. They are highly suited for the embellishment of borders and for what is now beginning to be termed the "wild garden."

THE EVENING FETE AT THE BOTANIC GARDENS,
REGENT'S PARK.

BY NOEL HUMPHREYS.

The evening of July 11, 1872, is destined to mark an interesting epoch in the annals of one of the most attractive of our horticultural institutions. Ever since the foundation of the Royal Botanic Society, its beautiful grounds in the Regent's Park have formed one of the favourite resorts of pleasure-lovers during each successive London season. The general flower shows, the Wednesday promenades, and the great annual Rhododendron displays, have for years furnished forth never-failing attractions; but the evening *fête* so successfully carried through last week, has left all other of the occasional festivals of that favourite resort far behind.

Just as the *fête* was about to commence, however, at a few minutes before nine, its success seemed destined to utter annihilation, by the drenching effects of a thunderstorm, for big, heavy drops of warning were rapidly succeeded by a close and continuous fall of soaking rain, during which the earlier arrivals continued without intermission, undismayed by the threatening state of the weather. As the great exhibition tent became filled with visitors, the clattering of the persistent rain was heard beating violently and unceasingly upon the canvas roof, and yet so hopeful was the pleasure-seeking zest of the guests that every one predicted a speedy cessation of the storm, although the flashes of white and vivid lightning above made the lime-lights below seem dull and yellow, and although the threatening notes of heavy thunder drowned those of the military bands. The rain continuing, confined the visitors for a time within the great exhibition tent and conservatory, all the external walks being soaked and sloppy, and the turf reduced to a thick carpet of water-saturated sponge; while the pretty shrubbery walks were in still worse plight, with more than half the coloured lamps extinguished, and the gravel under the refreshment tent had become a mere slosh. But such was the warmth of the air, that after the cessation of the rain, the walks became fit for promenaders, if not over scrupulous, in an incredibly short space of time. Meanwhile, there was much to see in the great exhibition tent, which it was a novelty to see by gaslight. The general effect of the exhibition of flowers and shrubs, as arranged for competition, was from several points of view exceedingly beautiful. The groups of various kinds of ferns, from the most minute and delicate to the most gigantic and robust, produced a very fascinating effect as seen by a bright artificial light; and varied as they were by the majestic foliage of palms, or here and there by a fine specimen of the delicate *Araucaria Ruleii*, or *Cocos Weddelliana*; the whole of the graceful expanse of foliage being enlivened at certain points by noble flowers of *Lilium auratum* rearing themselves in its midst, and at others by a cerulean mass of *Agapanthus*. The scene appeared, in short, absolutely one of enchantment.

One was glad to see, also, the finely-flowered masses of hardy herbaceous perennials, such as the Pentstemons and the Phloxes, and to learn from them what treasures of beauty are at our command for the embellishment of our open gardens, of which, comparatively speaking, we take such small advantage. The collection of Phloxes exhibited by Messrs. Downie, Laird, & Laing, and which took the first prize in its class, was truly magnificent in the gaslight, exhibiting every conceivable tint, from white and pale rose to the deepest tones of crimson, and even an approach to absolute scarlet; all the varieties being as hardy as a daisy or a dandelion. The same advantages in the way of hardihood cannot be claimed for the *Caladiums*, which require the protection of a conservatory, or the fostering heat of a stove; but, as exhibiting the most magnificent display of gorgeous foliage of any class of plants in the whole range of the vegetable kingdom, they never fail to arrest the attention; and when such a collection is brought together beneath the lights of an evening entertainment as that exhibited by Mr. R. Ritchie, who secured a first prize, the admiration of a plant-lover is raised to the highest pitch. Another feature that added materially to the picturesque and beautiful effect of the great tent, was the handsome rustic stand exhibited by Mr. Kepper. It was filled with exquisitely-grown Ferns, *Yuccas*, *Tradescantia zebrina*, and other suitable

plants, so exquisitely grouped and grown that a Van Huysum or a Miss Mutrie might have painted a masterpiece of composition from it without altering the position of a leaf or a line. There was also a special series of objects which commanded very general attention, as being seen to far greater advantage and more legitimately by artificial-light than daylight. I allude to the dinner-table decorations, which I found time to examine with some care, and which will be found described in another place.

Rambling from the great exhibition tent to the conservatory, I found a most charming effect produced by the vivid flame of the lime-light, which, coming from the outside, produced a kind of supernatural, fairy daylight, in which the palms and tree ferns and climbing plants, showing their dark outlines against the vivid external light, defined their endless variety of graceful form with a sharp distinctness that produced a very singular and at the same time beautiful effect. Leaving the conservatory, and going out upon the broad walk, a still more striking effect disclosed itself. The rain had ceased, the gravel was nearly dry, and a crowd of promenaders in evening dress of brilliant colours was moving in different directions, bathed in a luminous flood that was poured forth from the great lime-light above the chief entrance gate and from two others to the right and left, producing a dazzling effect that was at the first glance almost blinding, so much so that many ladies walked with spread fans before their eyes. The colours of the dresses shone out like the gleam of gems, and the gold and silver tissues of the robes of several Indian and Japanese princes added to the splendour of the general effect, which here and there was still further heightened by the unmistakable flash of diamonds, in the shape of tiaras, bracelets, necklaces, and other costly ornaments. No such evening *fête* upon a moderate scale has ever before been given in London with such brilliant success.

The music of many bands, performing simultaneously in various parts of the grounds, produced effects almost as magical as those of the lights. The ear was at one moment filled with one of the fullest and richest of the luscious melodies of Rossini, which, while still falling sweetly on the ear, seemed gradually but rapidly transfused into a crisp German march, which in its turn, after a few steps in advance, blended into a low, swinging waltz, to the metre of which clouds of great moths and other insects were seen whirling and whizzing in mad aerial dances, attracted by the unusual glare of light. The lighting of the magnesium torches at the lake was also a striking feature of the entertainment; now green, now red, now blue. Doubled by their reflections in the water, they formed an extremely picturesque feature, which the balmy softness of the evening enabled the lightest clad of the fair promenaders and sight-seers to enjoy, without the slightest fear of taking cold—though colds were doubtless caught, nevertheless, not singly, or in pairs, but by the score, by those whose feet were shod rather for the ball-room than the garden. As an evening garden party, the whole entertainment was so entirely successful, and so highly satisfactory to all concerned in it, that it will doubtless, we need hardly say, become an annual affair, as the climax of the great horticultural festivities of the season.

Development in Nature and in Man.—I should like to see a man's biography with corrections and emendations by his ghost. We don't know each other's secrets quite so well as we flatter ourselves we do. We don't always know our own secrets as well as we might. You have seen a tree with different grafts upon it, an apple or a pear tree we will say. In the late summer months the fruit on one bough will ripen; I remember just such a tree, and the early ripening fruit was the Jargonelle. By-and-by the fruit of another bough will begin to come into condition; the lovely St. Michael, as I remember, grew on the same stock as the Jargonelle in the tree I am thinking of; and then, when these have all fallen or been gathered, another, we will say the Winter Nelis, has its turn, and so, out of the same juices have come in succession fruits of the most varied aspects and flavours. It is the same thing with ourselves, but it takes us a long while to find it out. The various inherited instincts ripen in succession. You may be nine-tenths paternal at one period of your life, and nine-tenths maternal at another. All at once the traits of some immediate ancestor may come to maturity unexpectedly on one of the branches of your character, just as your features at different periods of your life betray different resemblances to your nearer or more remote relatives.—*Oliver Wendell Holmes.*

THE FLOWER GARDEN.

HONEYSUCKLES.

It is generally supposed that honeysuckles can only be enjoyed by those who have walls. This impression is erroneous, for these universal favourites may be enjoyed by everybody who has any extent of garden at all, though not a foot of wall be near it. Everybody loves honeysuckles; every poet has written of the woodbine; every posy we receive from the country is sure to contain trusses of its flowers; everybody remembers "that lovely cottage" with the woodbine half-choking the doorway, or half-smothering the window. The honeysuckle is not at all an aristocratic plant. The day labourer may have one rambling over his little arbour, and the countess allows another on the summer-house, provided it does not interfere with the "magnolia;" but, on the whole, it is banished from all "fine" gardens. To nail every shoot of it to the wall, with a multitude of nails and red shreds, is like putting a plant in a straight waistcoat. It must have liberty. There are three modes of growing honeysuckles apart from anything like masonry; for as a hedge or bush and a pole or pillar plant it is exceedingly well adapted. Wherever it may be desired to have a hedge of honeysuckle, either for its own sake or as a screen or a division, construct a slight kind of railing or paling, plant the honeysuckles about a yard apart, or less, if you think proper. Planted in good soil, they will grow vigorously, and as they progress they will require training. That is, do not allow half a dozen young shoots to coil themselves into a cable, but guide them, either by tacking or tying, so that the whole of the woodwork may be soon covered. When this is done it will require no further care than to reduce extravagant growths to something like order. Never mind symmetry, and there must be no clipping with shears; let it grow in its own natural way. A hedge of honeysuckle is one of the most beautiful sights in the world. Perhaps the Dutch honeysuckle, with its various tints of blossom (owing to the mutation of colour each blossom undergoes), is the best for this purpose. Bush honeysuckles are charming objects for the fronts of shrubberies, however choice. To form bushes, place three stout stakes triangle-wise at about two feet apart, and from two feet to a yard high. Put out a good plant in the centre, or one at each corner, and as they grow coil the shoots or "bine" round the stakes. They will soon make fine globular bushes, and will, with very little pruning, maintain their shape when the supports are gone. Pillar honeysuckles are very telling objects in the backgrounds of shrubberies and such places. Strong rough poles, from eight to twelve feet high, are placed as supports here and there in the background among shrubs. To these the plants are put; they soon run up to the top, and then fall over in wild bold masses—very beautiful. The trumpet honeysuckles are more delicate in habit, and do best in the most select spots, in the front of choice shrubs, supported with neat stakes from four to five feet high. The *Lonicera flexuosa* or *L. japonica* is evergreen, and has a habit unlike that of any other kind; the delightfully-scented blooms are axillary, in pairs, not terminal, like most others. This is the quickest-growing shrub I am familiar with, running from twelve to twenty feet high in a single season. It will grow (but not flower) in any situation, and is charming for covering unsightly gables and buildings. It will soon cover almost any amount of wall, on which, when covered, the branches should be left to grow naturally. A dead tree, especially one with horizontal branches, produces a fine effect when covered with this kind. Let it be tacked or tied when growing to most of the main branches, and then let it alone; the long flexible shoots will hang to the ground in every direction.—*T. Williams, in "Gardeners' Magazine."*

[In addition to the above desirable positions for these charming plants, they are also seen to great advantage when planted in a semi-wild state, on rough banks and slopes in the larger class of gardens.]

VARIEGATED-LEAVED PLANTS AT BIRMINGHAM.

THE collection of herbaceous plants with finely variegated leaves that interested me most, was that sent by Mr. Ware, of Tottenham. I went again and again to the side of the great tent where these were displayed, wondering each time, more and more, at the ignorance or supineness which prevents us from enriching our gardens with a number of these exquisitely beautiful plants, by means of which such endless variety might be secured to our borders, and the front of our shrubberies; by means of which, with foliage alone, and without the aid of flowers, most charming effects of chaste colour, both light and dark, may be produced. Such, however, is the ingrained conservatism of Englishmen, whether gardeners or politicians, that it will, I fear, be many years before we take the fullest

advantage of the variety and beauty which modern botanical discovery, and modern skill in culture, have placed at our disposal.

Many of the plants exhibited by Mr. Ware, too, were perfectly hardy, an advantage which cannot be too pointedly alluded to. In this collection, for instance, was a variety of the common sage, which, with its mass of gold-edged leaves, would form a very ornamental object, if placed in a situation to contrast strongly with shrubs of deeper toned foliage. The common sage itself, indeed, with its sombre foliage of semi-glaucous green, which is at present banished to the kitchen garden, might often be brought from its exile with advantage, to contrast with the darker or brighter greens of other low-growing plants. Mr. Ware's fine varieties of variegated *Funkia* form fine tufts of peculiarly handsome leaves; *F. undulata*, with its cream-toned leaves just flecked with streaky pencillings of green, being especially remarkable.

As a ground-covering foliage, where a low growth is alone desirable, what can be finer than the variegated Coltsfoot (*Tussilago Farfara*), so finely edged and brightly splashed with white as are some of the best variegated varieties? For spreading over rock-work, in favourable positions, what can be more desirable than *Sedum Sieboldii*, each leaf of delicate pale green blotched with a circlet of soft cream colour in the centre? And, then, the common old-fashioned border flower, *Polemonium carolinum* (Jacob's Ladder, variegated variety), is as pretty and bright an object as can be conceived. Each of its elegant pinnate leaves is edged with a clear sparkling border of white, making the foliage even more attractive than its pretty crown of soft blue flowers.

For fine semi-tropical effect, the noble leaf-blades of the variegated New Zealand flax (*Phormium tenax variegatum*) form a grand addition to *Yuccas* and other stiff-leaved Aloe-like plants. With this, the variegated *Yucca filamentosa* would group admirably. *Scrophularia nodosa*, with its white-bordered leaves and young sprays of golden yellow, is also very pretty; while the leaves of the variegated *Hemerocallis*, an old garden favourite, are so beautifully marked that a plant of it would form a fine object anywhere. There is also the smaller double-flowered variety, the leaves of which are conspicuously streaked with clear white, which would be very attractive wherever there is room for it.

All these, and many other plants with finely variegated foliage, were exhibited by Mr. Ware at Birmingham, each plant being a finely grown specimen; but in consequence of the intricate working of horticultural technicalities, which, as Lord Dundreary once remarked, "No fellow can understand," Mr. Ware was disqualified for competing for the first prize in this class, which he would otherwise most certainly have secured. Other exhibitors also sent fine collections of hardy and half-hardy variegated plants, containing specimens not in Mr. Ware's collection, especially that of Messrs. Bell & Sharp, among whose fine variegated plants I noticed the beautiful *Yucca Stokesii*, with lance-like leaves of the deepest green marked with a rich golden stripe along the centre; and also *Yucca aloifolia*, strikingly streaked with pure white, forming an exceedingly noble and picturesque object; there was also an exquisitely pretty striped grass—the prettiest of all the ribbon grasses—*Dactylis glomerata variegata*, which might be used in small patches with excellent effect in many places requiring sparkling touches of light; in short, Messrs. Bell & Co.'s collection was a very interesting one, but, on the whole, I was most attracted by Mr. Ware's plants.

In the class of shrubs with variegated foliage, I was much pleased with the selection shown by Mr. Standish, of Bagshot. There were several other collections which were probably as complete; but it so happened that the one sent by Mr. Standish fell in my way, and I was much struck by the beautiful character of many of the specimens. Time did not permit me to make any classification, and I find that in my memorandum-book I took the specimens as they came, in the following order, or rather disorder: The first thing that attracted my attention happened to be *Acanthopanax variegata*, forming a very charming little bush of mingled creamy white and pea green. Then came *Coprosma Baueriana*, an elegant shrub with golden-hued leaves of clean and regular form, marked by a spot of bright green in the centre. *Euonymus latifolia* and *E. radicans* are both of them attractive shrubs, and most useful in producing a special kind of effect; the former has leaves of pale cream colour marked very distinctly with two shades of green; some of the leaves remaining entirely cream coloured. The leaves of *E. radicans* are more regularly marked with cream-colour. There were also several other *Euonymus*, all more or less beautiful, as variegated shrubs. The variegated hollies were in endless variety, and no shrub or tree with variegated leaves can surpass this noble family. Golden yews, also, are very valuable, and of these, Mr. Standish showed some remarkably fine specimens.

There were two examples of *Cupressus Lawsoniana variegata*, with parts of the foliage entirely golden, producing at some little distance

off the effect of being covered with masses of rich yellow flowers. The variegated *Eurya latifolia*, with its long pointed leaves of mingled cream, grey, and green, is a very magnificent plant, inviting the attention of all such as wish to make a really grand addition to their shrubberies. Ivies grown as shrubs or standards, especially the variegated Japanese ivy (*Hedera japonica*), were not so fine in Mr. Standish's collection as they were in many others, nor were the variegated hollies; but on the whole his selection was a very noble one.

We have not as yet taken half the advantage which will be eventually derived from the large numbers of fine variegated shrubs which are now at command, both deciduous and evergreen; but the knowledge of them, and with it the taste for their culture, and the true feeling of the various ways in which they may become so immensely valuable in varying the effects, and imparting gradations of light and dark to our shrubberies, is being rapidly developed by such horticultural displays as that which has just taken place at Birmingham.

H. N. H.

A DOUBLE-FLOWERED WISTARIA.

Among the beautiful and rare things sent to America from Japan by Mr. Thomas Hogg, is a double *Wistaria*, which this year bloomed finely in the grounds of his brother, Mr. James

New double-flowered *Wistaria*.

Hogg. Flowers having the form of those of the pea (Papilionaceous, as botanists call them) are so peculiar in their structure that they are beautiful in their normal state, and ordinarily no advantage is gained by doubling them. In double flowers the number of parts is increased in various ways, and in many cases such are more attractive than when

single; but in Papilionaceous flowers the quaint irregularity of the arrangement is broken up, and we have in its place a confused mass of petals without any symmetry. The *Wistarias* are among our most common and valued climbers, and as they are used more for the general effect produced by their bloom than for the beauty of their individual flowers, the doubling in this plant is a manifest advantage. That which in the ordinary varieties is a simple pea-like flower, in the double one becomes a rosette of dark-coloured petals, and a raceme of these is very showy. To avoid answering questions about this *Wistaria*, we may state that the plant will be offered by one of the florists near New York when he shall have propagated a stock of it.—*Hearth and Home*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Lithospermum prostratum as an edging plant.—One of the most pleasing edgings I have ever seen, is in Mr. Harrison's garden, Bartrops, Weybridge Heath. It was more than a yard wide, neatly spreading, and dotted with flowers. It is growing on a very sandy soil.—W.

The Hardy Palm.—About four miles from here is perhaps one of the finest of specimens of the hardy Chinese Palm, growing in the open ground in the gardens of the Hon. and Rev.—Boscawen, at Bnan Laniorh. I did not measure it, but should think it cannot be less than fifteen or sixteen feet high. This was a female plant, and close by is a specimen of the male, a few feet shorter. Both are now in flower.—J. TYERMAN, *Tregony, Cornwall*.

Lychnis Haageana hybrida.—This is a novel and effective variety of this favourite perennial. Plants of it, six inches in height, are now flowering with me raised from seed sown in a greenhouse on March 22nd, thus making it almost an early annual. The flowers resemble in form those of the *Dianthus chinensis Heddewegii*, and in colour are scarlet, pink, creamy white, and other shades. It is a perfectly hardy plant, and makes a grand border flower the second year.—A. D.

Delphinium nudicaule.—This is undoubtedly an excellent addition to hardy border plants. In *Delphiniums* we have nearly every shade of blue, but the deep rich colour of the old formosum has made that variety first favourite in all gardens. It is indeed a superb blue, and as a June flowering border plant for back rows, cannot be excelled. I have now plants of *D. nudicaule* finely in flower from seed, sown in a cool house in February, and a charming thing it is; although, to do it justice, strong plants are required. The flowers are not so large as those of formosum, but the colour, a bright orange red, is undeniably good.—A.

Phlox Drummondii var. *Cardinal*.—This is the deepest and richest coloured of all this class of *Phloxes*, constituting, when in a mass, a rich glow of deep crimson such as one seldom sees equalled. It occasionally produces flowers of different hues, some of which are heavily shaded with purple. General Grant approaches it somewhat closely in colour, but that variety has more purple in it, and is not so showy. Varieties of *Phlox Drummondii*, to be done well, should be sown in a cool house, and, when the plants are large enough, they should be potted up singly into small sixties. Thus treated they get well rooted, and when planted out soon grow into strong free blooming plants.—D.

Pentstemons.—These make superb border plants, and deserve a greatly increased popularity. The improvement that has taken place in the quality of *Pentstemons* can scarcely be imagined by those who have lost sight of them for the past ten or twelve years. I have now in full flower a large bed containing some two hundred plants of *Pentstemons* raised from seed early in the spring of 1871. They all flowered strongly last autumn, and with scarcely the loss of a plant during the winter. They have now thrown up quantities of young growths that have been all through June, and will probably be all the summer, a mass of flowers. Their colours vary greatly; among them are scarlet, purple, pink, white, and intermediate shades of all kinds; their blooms too, are large in size, and the spikes long.—BENFORD.

INFLUENCE OF PARENTAGE ON FLOWERING PLANTS.

DR. DENNY, in his paper read at Birmingham on this subject, took the popular idea that the male pollen had much more influence than the female parent over the offspring, and spoke as if the raiser of seedling flowers could, with the knowledge now at command, raise his colours and produce new forms with almost the greatest possible certainty. My own experience, which has been pretty extensive, leads me to a very different conclusion. I believe no such rule exists, or if it does, the exceptions are nearly as numerous as cases which follow the rule. Having raised from three to six thousand seedling bedding geraniums per year for the last six or seven years, I was very anxious to see if any rules could be made out, but never could satisfy myself except in the case of variegated, or as they are called tricolor varieties. In raising these, I soon found it was necessary to save seed from green plants, and to use the pollen of the variegated, because seedlings from variegated plants were wanting in constitution; in fact, many of them could not be kept alive. But even in this case there were many exceptions, for I had green plants of great vigour as the result of this cross. Williams's Underwood was thus raised from Mrs. Pollock crossed by Woodwardianum. The seedling plants of this variety grew three feet high the first year, and though much pleased with the flowers, I thought it would be only fit for the back wall of a conservatory, but it proved a good bedder, and after being sold by thousands received a first-class certificate at Chiswick five or six years after it was raised from seed.

Those who think with Dr. Denny may say this is quite according to the rule, but many of the seedlings were almost white, and would not grow at all.

My practice has been to take the various colours, say scarlets, and cross the best habited plants with the best formed flowers, and *vice versa*, and to pick out the best of the seedlings the following year. That this has been very successful all who have seen my seedlings will admit. But last year, hoping to get some new colours, I tried crossing with opposite colours; pink on crimson or scarlet, and again scarlet on crimson or pink. Thinking to prove if there was any truth in the theories propounded, I had every seedling marked with the name of its female parent, and though many have bloomed and been thrown away, there are still perhaps a couple of thousand planted out, each with its name stuck against it. Dr. Irving, of Newark, was with me the other day looking them over, and we very closely examined them to see if any rule could be deduced from them. The peculiar foliage of the pink is well known. Here we have pink foliage with scarlet or crimson flowers, and zonal foliage with pink flowers; some take after the male, some after the female; some after both, and some after neither. The only good I have derived from all the trouble taken is the proof afforded that some kinds are good breeders and some bad ones. So much for Geraniums; now for Vines. I once raised about a hundred seedling vines between the American strawberry grape and several of our hot-house varieties. To those who do not know the strawberry grape, I may say its foliage is quite unlike any oriental variety, being small, seldom larger than a man's hand, very woolly, and almost entire, being nearly heart-shaped. Now all these seedlings had as their female parent the strawberry; the males were, as far as I remember, the Black Hamburg, Royal Muscadine, and Muscat of Alexandria. The foliage of the seedlings varied in a degree that was quite astonishing; some resembled their female parents some were much more like fig leaves than any vine leaf I ever saw before, and they varied in size and colour, as well as in shape. There were some amongst them with wonderfully large leaves, and yet all in some respects showed, in their colour or woolly texture, their hybrid origin. The fruit varied as much as the foliage in every respect, except size, for there was not a large grape among them, and generally, the largest foliage was accompanied by the smallest fruit. The fruit was of every colour known amongst grapes, but with a few exceptions (only two) they were all poor, but not all poor alike. Some were almost as astringent as sloes, some tasted like dirty water, and some were highly perfumed. Now I want to ask, can anyone deduce a rule for breeding from such a case as this? In conclusion, I would say, I think there are a few things we cannot know—the sex of a chicken before it is hatched, the sex of a calf before it is born, or which parents a seedling geranium will take after, though I know there are plenty of people who profess to understand these things.

J. W. PEARSON, *Chilwell*.

THE COMPETITIVE TABLE DECORATIONS AT THE ROYAL BOTANIC GARDENS, BY GASLIGHT.

At the recent horticultural show at Birmingham a darkened tent was prepared expressly for the exhibition of dinner-table decorations, as described in THE GARDEN of the 30th ult.; but at the Botanic Gardens, on the evening of July 11th, the table show was a genuine and legitimate night display. The decorations that obtained the first prize (as already known) were those exhibited by Mr. Buster; and, on the whole, they deserved that distinction. The central object was, as is so frequently the case, the very general tall vase of the trumpet form, at the mouth of which was a very elegant display of grasses, the feathery character of which is daily becoming more fully appreciated for decorative purposes. These were varied by maiden-hair ferns of two or more kinds, as well as by some other slender-growing species, sparingly and lightly used, and relieved only by three or four sprays of a delicate small-flowered white Campanula; while a careless additional grace was added by a trailing spray or two of, I think, *Maurandia*. The base of the tall vase was surrounded by a series of semi-circular glass troughs, which formed a scalloped enclosure. These low troughs were filled with forget-me-nots, mingled with water Ranunculus and a few small ferns, very delicately and neatly used. The two secondary objects consisted of similar vases, of lower proportions, rising from their own low saucers or plateaus, the vases being furnished in a somewhat similar manner to the central one, but yet ingeniously varied; the saucers having sprays of white Campanula rising from ferns, richly but sparingly mingled with roses. The small vases with button-hole bouquets were of the usual character, but very neat and elegant. On the whole, the general refinement of the arrangement of Mr. Buster's decorations was of a marked and very pleasing character.

The table which occupied the next place in excellence, in my estimation, was one decorated by the elegant taste and light artistic hand of Miss E. Harris, to which only a third prize was awarded. I was delighted with Miss Harris's composition; first, because it was not overdone; secondly, because it left broad spaces of the "best damask cloth," which is the greatest and simplest glory of the dinner-table, undisturbed in snowy whiteness by extraneous objects; and, lastly, because the decorations, as thus kept within the strictest bounds of tasteful propriety, were in themselves light and elegant. The grasses and ferns of her principal vases were delicately assorted and displayed, and were simply varied by a few sprays of dwarf white harebell, and one or two other objects as chaste and simple; while in saucers beneath were roses—only a few—nestling among fresh, mossy-looking ferns, and partially concealed by a feathery veil of lacey grass-blossoms. The general effect was full of elegant repose, which should always be aimed at, rather than that fussy, overdone profusion of decoration which is now so often seen.

A table decoration furnished by Miss E. Hassard, which obtained a second prize, was composed of six tall glass vases, from which rose graceful plumes of grasses, almost entirely unaided by the colour of flowers, being only just flecked here and there with a little starry blossom. At the bases were roses, white lilies, and geraniums, within a fringe of ferns. Altogether it was very pretty, and chiefly remarkable for the important part which common field grasses were made to play, with very elegant effect.

The adjoining table had a handsome silver epergne as a central object, well filled with the usual display of ferns, &c., the chief characteristic feature being the surrounding of the central epergne, and also the four corner ones, by favourite glass troughs, of pretty forms; these being filled with the best kinds of variegated geranium leaves, alternating with strongly-marked flowers, such as Pansies, blotched Pelargoniums, and Mimulus, with other kinds of flowers displaying two or more colours. The effect was original and striking, but perhaps wanting in repose. Mr. J. Mortlock's table, the vases and other ornaments of which were entirely of his white Dresden chinaware, must be considered (though well enough embellished with flowers) to be chiefly an exhibition of his elegant ceramic manufactures, which are remarkably well adapted for the successful display of floral decorations on the dinner-table. His gigantic dinner-table vase, furnished with palm leaves and a few large and striking flowers, looked remarkably handsome in the brilliantly lighted tent. Messrs. Daniels' table had a large mirror-plateau for a centre-piece, on which some small china swans looked very pretty with their forms reflected in the simulated lake, round which a border of water lilies did very successful duty. Messrs. Daniels can evidently exhibit very attractive table furniture. Messrs. Gardener's table, with a similar plateau, made much greater pretensions to importance. The swans, of real Dresden, were much larger, and of really artistic character, and instead of being placed on the mirror-lake, appeared as though forcing their way through the sedges and other foliage and flowers with which it was bordered. The vase of flowers rising from the mirror was of the usual kind. In two smaller plateaus of similar character, pretty Carrara groups of Venus and Cupid seemed floating in a graceful cockleshell on the mirror, surrounded by water lilies and suitable foliage. Small corner vases had Japan lilies, ferns, and drooping grasses of the great oat-grass kind, and in their saucers there were white sweet peas and delicate ferns. Altogether it was a very handsome table, but somewhat too profusely covered with decorations, which is a defect easily remedied on a future occasion. Mr. Charles Wood (floral artist) added a special feature to his floral decorations; richly plumaged birds being made to flutter round his table lamps, among the flowers with which they were wreathed; while he had for a centre-piece what he termed a "paradise fountain," the crowning feature of which was a bird of paradise, with spread wings drooping round, like a shower of pale amber, towards the flowers below. Messrs. Ward, also, exhibited "ornithological table decorations," as they style them, in which lovely birds nestled among the flowers in very picturesque fashion. But such novelties are, after all, of very questionable taste, and though pretty, and likely to be fashionable for a time, will scarcely retain a permanent place as legitimate dinner-table decorations. Miss Hassard obtained a prize for a table-decoration in which two large pots of growing ferns were the chief features, though the clay pots were entirely unadorned; for a dinner display such articles of the commonest kind of clay-ware ought surely to be clad in some kind of evening dress. The arrangement of table fruits by Miss Harris looked pretty and tempting in the glare of bright light, and the composition deserved the prize which it obtained. I have thought it worth while to notice these table decorations at some length, because they had previously been criticised by daylight, while their carefully prepared effects are intended to be seen, as a rule, by artificial light only.

H.

GARDEN DESTROYERS.

GEOMETRA (FIDONIA) PINIARIA.

We this week figure the different stages of a moth which has great capabilities of mischief to our young fir plantations. It has not indeed yet been found to be so serious an enemy to them in this country as it is on the Continent; but still it is desirable to point it out to our gardeners and arboriculturists as a species which is to be looked on with a certain amount of suspicion; for, as it is not rare throughout Scotland and England, there seems no reason why, on the occurrence of favouring conditions, it should not develop itself to the same extent as across the channel. We believe it has not yet been recorded as found in Ireland; but this is probably rather due to want of observation than to its actual absence. It occurs all over Europe, and is especially abundant in Germany, where its ravages have been greater than anywhere else. The numbers in which it appears are sometimes very great. Ratzburg notes of one winter that as many as seventeen thousand pupæ had been gathered on a single acre. As

Geometra (Fidonia) Piniaria.

might be expected, when it occurs in such numbers it entirely strips the trees of their leaves, and of course weakens, injures, and sometimes destroys them.

It is the caterpillar that does the actual mischief. It feeds specially on the leaves of the different species of pine, although it has also been found attacking the spruce fir. It prefers the young trees to the older. The caterpillar is of a glaucous green colour, with a whitish stripe up the back, and another less distinct, and slightly bluish-white, along the sides, and a yellowish strip next the abdomen, which is streaked with different shades of green. Although not in itself bearing any resemblance to a pine leaf, its colours harmonize so perfectly with the leaves that it cannot readily be distinguished when feeding upon them.

The chrysalis is dark-brown. The moth is differently coloured in the two sexes, besides the usual distinction of plumose antennæ in the male and filiform antennæ in the female. The male is dark-brown, with yellowish-white patches.

The female is entirely of different shades of brown, and is darker than the male, but the dark shade of brown is not so deep, and the brown redder. In the male the brown is burnt umber; in the female it is umber qualified by burnt sienna. The lighter portions in the female are merely paler than the rest of its colour, but of the same tint. The eggs are oblong, and laid in rows on the leaves of the pine.

The moth appears in April and May, is most frequent in June and rare in July, in which month the caterpillars begin to show themselves. They grow very slowly, and do not go into pupa until October or November. Hence we infer that they have only one brood in the year.

Hand picking, after shaking and heating the caterpillars off the trees, is the remedy that has been recommended; but, as is too often the case with insect ravages, our own efforts at abatement are very feeble, and we are more dependent on the influence of the seasons and the interested labours of their own special enemies than on anything else for any immunity we may enjoy.

A. M.

Sulphozone, a Substitute for Sulphur (see p. 31).— May I be permitted to inquire by what process sulphurous dioxide impregnates pure sulphur? One might as well talk of sand being "impregnated" with a gas. I am astounded at the statement that the insecticide and other properties of powdered sulphur are due to the presence of sulphurous dioxide. Every chemist knows that this powerful acid gas first reddens and then bleaches all vegetable tissues. If any gardener doubts this fact, let him burn a piece of brimstone in a dry atmosphere; the product, which is supposed to be the active agent in powdered sulphur, will bleach any plant introduced into the apartment. I should very much like to know how it is possible that this gas gets into sublimed sulphur. Sulphur must of necessity be sublimed in vessels absolutely free from air, otherwise it would not sublime at all, but be converted into the gas which Mr. Roberts imagines it contains. I need scarcely point out that if any small portion of air were accidentally present it would at once be destroyed by the sulphur, and so prevented acting on any further portion of the subliming body. It is most reasonable to suppose that sulphur acts mechanically and chemically, first, by smothering or irritating animalculæ, for which purpose, of course, sublimed sulphur would be preferable to the same substance in a powdered state; secondly, by the almost imperceptible action of hydric chloride upon it. This acid is always present in rain and moist vapours, and its slow decomposition in presence of the fine particles of sulphur would effectually destroy any animal organism. In Professor Balfour's "Botany" it is stated (p. 147) that "Sulphurous acid gas (SO₂) is highly injurious to plants. It produces greyish-yellow, dry-looking spots on the leaves, which gradually extend until the leaves are destroyed and fall. . . . The proportion of this gas in some experiments was only one in 9,000 or 10,000 parts of the air, and the quantity one-fifth of a cubic inch. And yet the whole unfolded leaves of a mignonette plant were destroyed in forty-eight hours. This proportion of gas is hardly, or not at all, discoverable by the smell." So much for "sulphozone," whatever that may mean.

W. R.

Gooseberry Caterpillar.—There is no occasion for experiencing a single day's annoyance on account of this caterpillar. Water the branches affected, and, while wet, sprinkle some freshly-powdered hellebore over them. In a few minutes the grubs will have made themselves scarce, and will not return.—
BROADLEY HARRISON, *Eynaston, near Ross.*

THE ORIGIN OF THE MOSS ROSE.

(FROM THE GERMAN.)

THE angel of the flowers one day,
Beneath a Rose tree sleeping lay,
That spirit to whose charge 'tis given
To bathe the young buds in dews from heaven.
Awaking from his light repose,
The angel whispered to the Rose,
"For the sweet shade thou'st given to me,
Ask what thou wilt, 'tis granted thee."
The Rose replied, with height'ning glow,
"On me another grace bestow."
The angel paused, in silent thought,
"What grace was there that flower had not."
'Twas but a moment, o'er the Rose
A veil of moss he lightly throws;
And, robed in Nature's simplest weed,
What other flower ean this exceed?

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 5.)

MANURES.

The manuring of pot plants is effected either by mixing solid manure with the soil, or by placing it on the surface, or, lastly, by watering with liquid manure. Solid manures, for mixing, comprise the various composts of stable manure or cow manure in a thoroughly decomposed state, and which may be obtained at the nurseries. Of these, cow manure compost is, for general purposes, to be preferred. It should not be mixed, however, in a greater proportion than from one-tenth to one-fifth of cow-dung in the entire mass. Other stronger materials are horn-shavings, bone-dust, malt-grains, powdered fowl's-dung, &c. Small quantities of these are mixed with the soil for those plants which are known to love strong manure, such as Petunias, Fuchsias, &c. As powerful manure, when mixed with the soil, often produces a very bad result, it will be sufficient, in general, to place it on the surface of the soil in the pot, so that in the course of watering it may be gradually dissolved. Of this class of manures are guano, fowl's-dung, bone-dust, malt-grains, &c. It is much better, in room culture, to use liquid manure, which has this great advantage that it can be given to the plants exactly at the time when they require more nutriment—during the seasons of growth, of bud-forming, and of blooming. On the other hand, during the period of rest, solid rich manure mixed with the soil is less likely to prove injurious, or to render the plants sickly in the winter season. A mild kind of liquid manure, which every house will supply, is the water in which plates, &c., have been washed, and the water in which meat has been washed before cooking. Both of these may be given to the greater number of plants during the whole time of their growth and blooming, if the plants are in a healthy condition.

LIQUID MANURE.

To prepare a strong liquid manure, a tub is filled with water, into which is thrown fresh cow-dung, pigeon's or fowl's dung, blood, scraps of flesh offal, guano, bone-dust, &c., either one or more of these matters being used. To hasten the decomposition of these, some muriatic acid may be added. The vessel should not be covered, but the air should be allowed to have free access to the liquid. It should also be stirred up from time to time. As soon as fermentation sets in, it is ready for use. It should be poured through a sieve into the watering-can, and applied to the plants in the morning and evening. It is advisable to dilute this with more water if it should be too concentrated, as then it is injurious. Experience and observation of its effects will soon teach whether it is too strong or not. Liquid manure such as we have described, if used at the proper time, is one of the best means for securing a luxuriant growth and bloom.

KEEPING THE PLANTS CLEAN.

One of the most unfavourable things to the culture of plants in rooms, and especially in living-rooms, is the dust, which in a short time covers the leaves and, indeed, all parts of the plant above ground. By it the pores of the leaves become choked, and the process of transpiration is either totally stopped or else seriously impeded. The leaves then begin to turn yellow, and, unless the evil is arrested in time, the plant becomes sickly, and at last dies. In order to avoid this, the plants should be cleaned as often as possible with a dry soft cloth or with a wet sponge. The latter, however, should be free from any particles of lime or sand, which would injure the tender skin of the leaves. It is best to give the plants a double cleaning, first with the dry cloth, and then with the moist sponge. A cleaning of this sort is the most complete, and at the same time refreshes the leaves, which so easily suffer from the dry air of the room. If they are merely wiped with the wet sponge, the dust will not be so completely removed and the leaves will not preserve their soft shining green colour, as they would if the dust was first removed by the dry cloth. A trial will prove the truth of this statement. The more frequently the plants are thus cleaned the more

healthy and luxuriant will be their growth. In plants with soft, velvety leaves, and also in such as have leaves and stems covered with a woolly pubescence, it is recommended to remove the dust by means of a fine soft paint-brush. The cleaning of the plants consists not merely in wiping or washing the healthy leaves, but it is also of the highest importance to remove as speedily as possible all dead or decaying foliage. Deciduous plants, and also evergreens with articulated leaves, will either of themselves shed their dead leaves, or when they turn yellow they may be easily plucked off without injury to the branches. In the case of evergreen plants, the leaves of which are firmly attached to the branches, such as Aroids, Scitamineæ, Ferns, Palms, &c., the yellow leaves must be cut off, as by careless plucking them off the stem may be injured. In the case of many evergreens of which entire shoots die off, these must be so cut away with a sharp knife that no stump may remain, and so that the wounds may soon cicatrize.

POTS.

The pots in which plants are grown in rooms should also be kept clean. Even with careful watering, the surplus water will sometimes be allowed to stand in the saucer, and in consequence the outside surface of the pot will become covered with a layer of whitish or greenish matter arising from the growth of mould-fungus or germinating moss. A properly baked pot is very porous, and allows the air to penetrate through it to the roots of the plant, which is absolutely necessary to its proper nourishment and healthy growth. As the dust impedes the transpiration of the leaves, so does the deposition of this whitish or greenish matter on the outside of the pot prevent the air from passing through it into the ball inside. Wherever it occurs, therefore, it should be carefully washed off. Frequent loosening of the surface soil, especially when the plants are watered with liquid manure, and the removal of every weed are, for the same reason, to be recommended.—*Dr. Regel.*

(To be continued.)

LEAVES FOR GARNISHING THE DESSERT.

A RARE old leaf is the ivy, green or golden, for garnishing fruit. And yet its smell is anything but sweet, its taste is rank and poisonous, and it leaves somewhat of both on the fruit it adorns. Therefore, beautiful as the ivy is, it ought not to be brought into contact with fruit. The Portugal or common laurels are much better. Unless bruised, they give out little odour, and no taste. Their size is suitable, and their bright glossy surface cleanly. The colour, especially of the Portugal variety, is a rich dark green, and the forms of both are well adapted for association with dished-up fruit. Hollies, especially the plainer-leaved varieties, form beautiful garniture for desserts, and give out neither smell nor taste. Even the pricklier varieties, both green and variegated, may be turned to useful purpose by using terminal tufts instead of single leaves. These can be handled better, and the little rosettes, set off with prickles as defensive armour, guard the fruit from danger, and force us to handle it with care. Aucuba leaves are very handsome, but they smell rather strong, and many of them are too large, even were we prepared to pluck the leaves of the finer sorts. The common *A. japonica* is the best for this purpose, and, setting aside its smell, is very pretty. The *Berberis Aquifolium* and other species afford the most useful of all leaves for garnishing the dessert. They yield so many leaves of different sizes and colours as to furnish a rich variety; they are also clean and scentless, and fit in well with most fruits. *Rhododendron* leaves are bright and glossy, and look well either singly or in terminal branchlets. *Laurustinus* is clear, bright, shapely, and has a good effect. The *Arbutus* is also clean and pretty, in terminal bunches or single file; and Sweet Bay leaves are light, glossy, and sweet, without, however, flavouring the fruits that rest upon them.

Notwithstanding all this matter of choice, many, however, elect to cushion their fruit on variegated or green kale. It is pretty enough, but both the sight and smell are suggestive (often highly so) of cabbage, which is a somewhat incongruous association with a luscious dessert. All leaves from the outside should be washed and well dried before being used. Frozen leaves will lower the quality of most fruits that touch them, and nothing can be more displeasing than the adorning of choice fruits with imperfect or unclean leaves. Therefore, gather the leaves for the garniture of your dessert early in the morning, sponge them perfectly clean, if not already so, and lay them aside in a temperature 10° or more above freezing, but not

in sunshine; they will then be in a proper state for use when wanted.

Those who grow stove or greenhouse plants in quantity—and especially climbers—or force early fruit and flowers, will hardly ever be scarce of choice leaves for the garnishing of their desserts. And yet it is by no means every pretty or fine leaf that is suitable for this purpose. For instance, the whole family of pelargoniums must be set aside, from their excess of perfume. There are other beautiful leaves, again, that are too thin to go creditably through a dinner without shrivelling up into needless incumbrances of the dessert. Such is to a great extent the case with *Abutilons* of all varieties—very fresh and beautiful, but fragile. The leaves of the variegated and the common form of *Cobæa scandens* have the same failing. Again, there are some of the passion-flowers that give out a disagreeable odour, and some of them, like *P. quadrangularis*, are too large; and *kermesina*, in a young state, is almost too tender. Still, this noble family is rich in leaves for garnishing. *P. alata*, *edulis*, and *racemosa* being among the very best species, are also rich in beautiful leaves; but some are fragile, and those that are suitable have more or less scent. *Camellia* leaves are models of smooth, glossy beauty, but no one cares to gather them for fruit garnishing; while those of oranges, lemons, &c., are too highly perfumed. *Stephanotis* are too leathery, were one inclined to pick them off. The early forcer of fruit and flowers can seldom, however, be at a loss for choice foliage for garnishing desserts. Even common leaves out of season acquire an uncommon beauty. Of course those who have vine leaves need no other; nothing can supersede nor equal them. They are the best of all, from the time the tender picking will barely pass through the dinner till the winter leaves of many colours crumple into a handful of dust in our fingers. Early fig leaves are also admirable. Later in the season they seem too rough and common for choice fruit; but the early leaves have a soft freshness that is most pleasing. Even early peach, plum, pear, apple, and cherry leaves are admirable; while the leaves of forced roses have a cleanly beauty that is seldom seen on those out of doors. The lily of the valley leaf, with a flower or two here and there, gives one of the choicest, sweetest finishes to a dessert, without flavouring the fruit. A fine Czar violet and leaves of the common primrose are by no means to be despised. That most useful of all plants for cutting, the *Astilbe japonica*, yields a harvest of exquisite leaves for the adorning of the dessert. Again, forced lilacs, especially all the varieties of the Persian, are invaluable. Doubtless a considerable proportion of the charm arises from the fact of the leaves being out of season; but they are likewise more beautiful, that is, more fresh and green, when produced under the shelter of glass. It is astonishing how much variety of garniture adds to the interest and beauty of the dessert. And this reminds me of another set of leaves which I have not named, that are amongst the most useful and beautiful of all—those of the strawberry. This fruit never looks so well as when nestling upon its own leaves; and doubtless desserts generally would be far more interesting and beautiful than they are if, as far as practicable, early fruit were adorned with leaves or branchlets of its kind.

BETA.

SHOW OF WINDOW PLANTS AT HULL.

(JULY 6TH.)

No one will, I think, dispute the value of those floral tournaments that were at one time confined to the great metropolis, but which in recent years have been distributed more generally through our great industrial centres. Wide, however, as the basis may be upon which those pyramids of *Flora's* beauties—so often recorded in your pages—are built up, there is still a wider, and if, in extending that basis, we lose in altitude as representing quality, I trust the interest of the "thousands" as compared with the "tens" will amply justify me in asking for space in your well-filled columns, for a brief report of a somewhat modest, though none the less interesting, exhibition held in the Public Park, Hull.

Some six years ago, the Hull Window-Gardening Society was established, its primary object being to encourage a love of flowers among the working population of that town, and with this object in view, its attention and its means (somewhat slender) were first devoted to a distribution of such plants as the possessors of flower gardens in the neighbourhood could contribute, in the autumn; and, secondly, to the awarding of prizes at an exhibition of those plants held during the following summer. This limit as regards the exhibitions was, however, enlarged, for two reasons: the one to extend their interest, the other to increase their popularity; and by this means to include, not only the recipients of plants so distributed, but all those that previously cultivated plants in their windows. So varied are the circumstances under which window plants may be cultivated, bearing in mind aspect, density of buildings externally, or density of population internally, and innumerable other modifying influences, that it was deemed advisable to divide all exhibitors into three groups, classified as

A, B, and C, according as those influences were good, moderately good, or bad. With a view to facilitate those who undertook the "registration" of the plants, a code of instructions was prepared, showing the conditions under which the several letters would be applicable, thus placing each competitor fairly in the field—white against white, green against green, and brown against brown. I have alluded to "registration," and possibly, at the onset, had better explain what is meant by this title.

The value of such an exhibition depends very much on its *bona fide* character, that is, that the plants so exhibited shall have been cultivated in a window during at least a moderate length of time, say six weeks or two months; and to secure this most important point beyond dispute, the services of those persons, who either by position or by inclination were readily enlisted in the furtherance of so good an object, were secured; and these, visiting the proposed competitors, not only inspected the plants, and determined the classes in which they should be exhibited, but, further, by means of small cards, eyelets, and red tape, and the assistance of a pair of nippers, each plant became registered, bearing on the card the number of the exhibitor, and on the sheet in the hands of each registrar was entered the name, residence, and occupation of the owner, as well as any further matters that might be of interest. To quote one return will show the interest and value of such data, viz., "Cultivated by the same person for thirty-five years." A schedule of prizes, about ninety in number, varying from one shilling to six shillings each in value, was prepared, and these were apportioned not only to the A, B, and C groups of registered plants, but also to bouquets of wild flowers, designs in wild flowers, designs in grasses, and collections of wild herbs gathered in the neighbourhood. I omitted to mention that, besides these registered window plants, others who possessed plants, were invited to compete in a class by themselves, and special prizes were awarded to the most meritorious. From this description it may be seen that the prospect of a varied and interesting exhibition was secured, the monotony of the plants being relieved by the beauty and elegance of the designs in grasses.

The show was held in a marquee one hundred and fifty feet long by fifty feet wide, and when I say that the centre stage, consisting of three tiers, was well filled from end to end, two projecting semicircular tables in the centre accommodating the grasses and wild flowers, the reader will readily understand that the competitors must have been numerous. If there was a lack in brilliancy of colour, this deficiency was more than compensated by the variety of objects exhibited; and what a history—what a halo of old associations surrounded many of those plants in the eyes of the exhibitors! It was amusing to see how tenderly they set them down, and how carefully they arranged every leaf. Did time permit me I could give many little episodes that came to my ears on the morning of the exhibition.

The exhibitors on this occasion numbered upwards of 340, of these about one half belonged to the registered classes; and I may here remark that a glance at the three classes as separately staged, gave practical proof of the value of this system of classification. About eighty competitors entered the lists for wild flowers and grasses; these were chiefly children, varying in age from six years old and upwards, and equally various were the designs they produced—from simple, unpretending little bunches, culled from the roadside, to elegant designs of the most elaborate type. Non-registered plants, numbering about two hundred, were exhibited by about fifty competitors, and, thanks to the liberality of some of the tradesmen, many useful and elegant prizes were available; nor were these prizes one whit less miscellaneous than the articles exhibited. At one end of the centre stage a window was fitted up, with a box for the window-ledge outside made to extend beyond the window-jamb one foot on each side. In the extended portion, Ivy was planted and trained up the margin of the window, presenting a very pretty effect. Plants were also arranged in the interior, and a famous plant of the old "Mother of Thousands" (*Linaria cymbalaria*) formed a beautiful object suspended in the centre. This window was fitted up by the Society to show practically what might be done with simple means in the way of decoration. Of course, there was the usual accessory of music; and when I say that as much as £18 was taken at the entrance to the marquee in pennies and twopences, we may roughly estimate the visitors at about two thousand or more, besides the exhibitors, each of whom had a special ticket.

The prizes were distributed from a platform, at the close of the afternoon, and to each prize-winner was also given a copy of instructions on the management of window plants, prepared especially for the purpose, in the form of a small pamphlet. I may add that it is further intended to make a distribution of small plants concomitant with the exhibition another year, so that each exhibitor will receive a plant or two, properly selected and prepared for window culture. This will be substituted for an autumn distribution, which has proved itself, practically speaking, of little value.

I have gone thus far into the details of the above exhibition so as to place before your readers, who may be interested in the window-gardening movement, an outline of the working of our Society. Should any such be wishful to possess the various "forms" that we have adopted, and which have been, of course, considerably modified by experience, we shall have great pleasure in supplying the same.

Hull Botanic Gardens.

JAMES C. NIVEN.

The Avocado Pear.—The correspondent who has recently inquired about the way to raise the seed of this exotic, may be interested to learn that its large seed will grow freely if placed on a hyacinth glass, just as we place a hyacinth bulb, and it may be raised thus in a sitting-room. I had the pleasure of seeing a very healthy plant of it raised thus in Mr. Wilson's dining-room, at Heatherbank, Weybridge Heath. It is yet growing freely in its hyacinth glass, and is about fifteen inches high, and has been in the same position for months past.—W.

SOILS, MANURES, &c.

ARTIFICIAL MANURES AND THEIR ADULTERATION.

PROFESSOR VOELCKER says: You cannot by any inspection recognise whether guano is adulterated or not. I defy, he adds, even an adept in guano to tell me whether this specimen is genuine or otherwise—it is so like the genuine article. Chemical skill is required to effect a detection, but chemical skill can do it. There are, however, one or two things which it may be useful to remember, inasmuch as they will enable people to detect pure Peruvian guano from the adulterated kinds. The best Peruvian guano always has a lighter specific gravity than adulterated kinds. If you weigh a bushel of the genuine stuff, you will find its weight per bushel does exceed sixty-nine pounds. It is usually from sixty-eight pounds to sixty-nine pounds per bushel; that is to say, a bushel measure filled and struck off. Adulterated guano always weighs more. This surely is a simple way of testing the value of guano. Another equally simple way is to burn a small quantity. If you have the appliances to do it by careful weight, take one hundred grains. Should the guano be genuine, it will leave one-third of its weight in ash, which is perfectly white; in other words, sixty-six grains will burn away, and thirty-four will remain in the form I have stated. If the guano be adulterated, it will leave perhaps more than one-half of its weight in ash, and the ash will invariably be coloured, since the earthy matters which are usually employed contain oxide of iron, and that compound causes the ash to be of a brownish or yellow-brown colour. Genuine Peruvian guano yields from sixteen to nineteen per cent. of ammonia. The materials that are mixed with guano are gypsum, chalk, and certain yellowish loams.

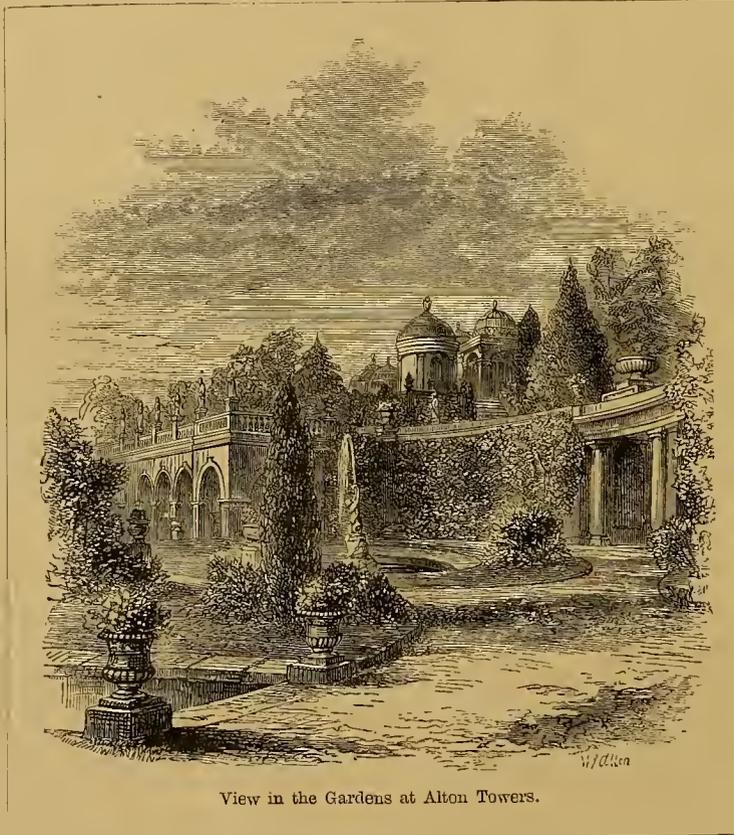

Analyses, I am sorry to say, are frequently made for mere gain; they enable unprincipled dealers to sell spurious articles. It frequently happens that when guanos are offered for sale an analysis is shown with them of a highly recommendatory character; whereas the bulk which is sold to the unwary purchaser is totally different from the sample which was submitted to the analyst's hands. A sample was sent to me, and analysed according to request, and I know positively it was afterwards mixed with a large quantity of yellow sandy loam, and sold by auction as genuine material on the strength of my analysis. It was sold at prices varying from £7 to £9 per ton, and yet it was not worth more than £2 to £3.

Nitrate of soda is frequently mixed with common salt. Sulphate of ammonia is another valuable manure which is occasionally adulterated, the chief adulterating principles being sulphate of magnesia or Epsom salts, sulphate of soda or Glauber salt. Bone-dust is not often adulterated, unless you buy it in a very fine powder, and then you run the risk of getting gypsum mixed with it, or you may possibly get with it vegetable ivory, which resembles fine bone-dust very closely. From a manurial point of view this is not worth anything; but it is good as an adulterating principle, and the button manufacturers of Birmingham will not take less than £2. 10s. or £3 a ton for it. Dissolved bones and superphosphates are sold at high prices, and the prices which you ought to give for this description of artificial manures should be regulated entirely by their quality. You cannot fix one uniform price for superphosphates; everything depends upon the composition. There is only one way of determining their

value, and that is by analysis. The constituents which chiefly regulate the value of this description of fertilizing agent are soluble phosphate, insoluble phosphate, and nitrogen, or ammonia. The more you have of soluble phosphate and bone phosphate and of nitrogen, the better the artificial manure, and, of course, the more you will have to pay for it.

There are some mixed artificial manures the names of which do not exactly indicate their true character. For instance, a good many kinds of manure are sold under the name of blood manures. As a fact, there is very little blood used in the manufacture of manures. Where is all the blood to come from that would make all the manures sold under the name? Some of the manures, nevertheless, are very good—not on account of the blood, but other good things of which they are made. Whilst some refuse materials, as blood, or even woollen refuse, are useful in furnishing nitrogen to the growing plant with sufficient readiness, there are others which do not decompose, and which are only added with the view of deceiving the consumer. Leather, for example, is out of place in manure, even after it is steamed and subjected to the action of sulphuric acid.

To sum up, in buying guano it suffices to have the guarantee of the dealer that the article is Peruvian guano of the best quality. You require no analysis—the guarantee is generally sufficient. In buying nitrate of soda, buy according to the percentage of pure nitrate: in good samples you should get from 94 to 95 per cent. Sulphate of ammonia buy according to the percentage of ammonia: in good commercial samples you ought to get from 22 to 24 per cent. A guarantee that bone-dust is genuine will be quite sufficient. In buying superphosphates the first thing you have to do is to make up your mind as to what you want. Do you require mineral superphosphate or bone manure? According to your requirements let the guarantee be shaped. Mineral superphosphates are useful when the ground is in first-rate order; when it is not too light, or has been manured previously in the autumn, they are very useful, and in buying them all you require is to have the percentage of soluble phosphate guaranteed. If, on the other hand, you buy bone manures, you not only require the percentage of soluble phosphates guaranteed, but also

View in the Gardens at Alton Towers.

that of the insoluble phosphates, and, moreover, a distinct understanding that the insoluble phosphates are present really as bone, and not in the shape of coprolite powder, Estramadura phosphate, or any other description of mineral phosphate.

THE GARDENS OF ENGLAND.

ALTON TOWERS.

AFTER the period of classic order and exactitude alluded to at p. 15, when every tree and branchlet corresponded with its neighbour as much as if it had grown by rule, came the reign of nature, pure and simple. Circumstances, to which it is not needful to advert, gave liberty to the captive trees, loosened them, and let them grow into freer and larger forms. The tree and shrub wealth of the "Enchanted Valley" became too great for its limited area. Classic monuments, pagodas, fountains, Gothic temples, Swiss cottages, Arcaded walls, domed conservatories, all became partially entangled and hidden in a maze-like thicket of choice vegetation.

Rich views were choked up; distant prospects blocked out by impenetrable foregrounds. The gardens were still beautiful, but they could only be seen in detail; and as the trees grow larger, less and less of the narrow valley could be seen from any one spot. In many gardens this is an advantage; the gradual unfolding of beauty makes it last longer and tell better. There are gardens which affect one exactly as a sky-rocket; you enter, and the whole bursts on the eye at once, and then all is over. Such gardens are not satisfying; a reaction sets in. But Alton Towers is an exceptional place. The valley, on each side of which the gardens are laid out, is narrow and delightfully varied. The nature of the ground and style of furnishing, afford a succession of varied scenes, each beautiful and distinct. Architecture, sculpture, classical associations, water, all, to a certain extent, pervade this vale of beauty, and each stamps some particular scene with its own distinctive features. The eye has no time to weary till it is arrested by a fresh object, and there are depths of meaning and of beauty in these gardens which the visitor cannot readily reach.

The woodcuts we now give, and scores more might be given, illustrate and confirm these remarks. Even the same scenes, viewed from different stand-points, seem wholly distinct and different. Almost every part of interest thus serves several distinct purposes. It is beautiful in itself, a unique distinct complete scene, and it likewise forms part of a complete whole. Of late years, the efforts of the present Countess of Talbot and Shrewsbury, and her able gardener, Mr. Rabone, have been specially directed to the creation of wider views of this charming valley. Nature had, in the course of time, overgrown art too much. The difficult problem was to cut out art in due proportion without marring the face of nature. And difficult work it was. Sculpture and architecture need the furnishing and balancing of trees and shrubs, to clothe, as it were, their baldness, and the eye of refined taste soon determines when they have had enough toned down. But to cut out works of art or the beauties of a landscape is a high effort of taste and genius; nevertheless as far as it has proceeded, it seems to have been remarkably well done at Alton.

Several parts of the grounds would bear more cutting. Here and there fine specimens are injuring each other; it is impossible to save all, and some ought to be sacrificed. Again, other features, such as the Swiss cottage, would bear a little more opening up. It would be more effective from the other side of the valley were another tree or two removed; and similar remarks are applicable to other parts of the grounds. The trees must either be kept small or some of them removed, or a tangled thicket, rather than a garden, will be the ultimate result.

Our views give a good representation of the general

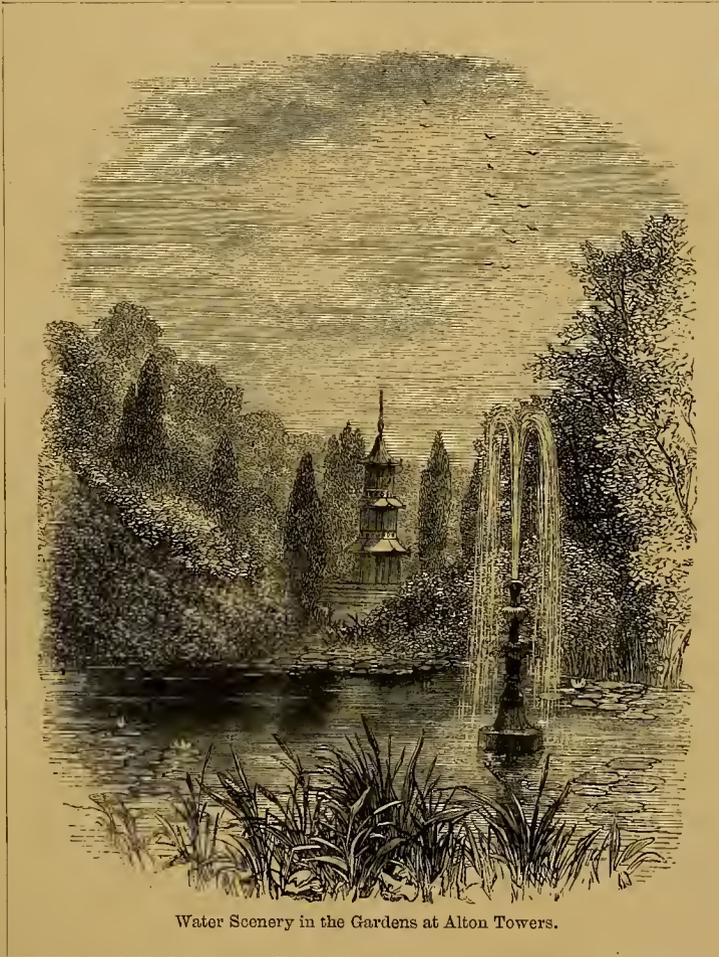

character of the garden. The most notable points, apart from their well-furnished base, covering each side, the bottom, and upper end of a narrow valley, are the architectural ornaments, spiral trees, and water. There is a noble lake near the house, and cascades and fountains all over the grounds. The more permanent among the latter are the Screw, the Pagoda, the Bath, the Dolphin, and the War fountains, the latter so called from the jets of water being sent forth in direct antagonism to each other. Stonehenge, Jacob's Ladder, or Flagstep walks, three hundred yards in length, the domed conservatory, panelled walls, golden, Gothic, and other temples, La Refuge, alcoves, Swiss cottage, statuary, &c., furnish a wealth and variety of architectural adornment rare in gardens of much greater extent. And the style of gardening is most comprehensive, and may be said to include all styles. There are ribbon borders, mixed borders, and beds; sub-tropical, Italian, Dutch, and

common flower gardens in succession; each, as it should be, distinct in itself, and not a medley of all styles in one, which seems the rage in certain quarters, but which is the most monotonous of all modes of furnishing, landing us in a dead sea of mediocrity without a wave of beauty or interest to stir its dull leaden surface. On the contrary, at Alton Towers one bounds along from one distinct scene of interest and beauty to another, without weariness and fatigue, and each fresh garden affects one's spirits like the opening of a new book by a favourite author. The marvel is that so much beauty and interest can be packed into so little space; for, after all, the valley is narrow, and not unlike a huge nut laid open, the inner edges, being packed full of rich vegetation, watered copiously from flowing fountains, and adorned with temples of art, in which the visitor may rest and be thankful.

Mr. Rabone has the difficulties of a public garden to contend with, and the wants of a large private place to supply. He fulfils both duties to

the satisfaction of all. Cut flowers are in great demand at the Towers, and roses, violets, lilies of the valley, orchids, mignonette, &c., are had in quantities throughout the year. A large collection of orchids and stove plants is cultivated, and there is also a splendid display of fine azaleas, camellias, &c.

Fruits of all sorts are also well and extensively grown; and the grapes are so large and fine as to have taken high honours at the show of the Royal Horticultural Society at Birmingham, the other week. A new rosary, consisting of about two thousand plants, has recently been added to the gardens, and altogether, culture and taste and energy are doing their best, not only to maintain, but to extend the fame and the beauty of this charming place. Of Alton Towers, it may be emphatically said, it must be seen to be understood and appreciated. D.

Water Scenery in the Gardens at Alton Towers.

THE FRUIT GARDEN.

THE FUTURE OF OUR FRUIT CROPS.

READ BY GEO. WESTLAND, AT THE BIRMINGHAM CONGRESS.

WITH a rapidly increasing population, the question of our fruit supply becomes important. Fruit, among the working classes, has too long been looked upon as a luxury. A hale and hearty sexagenarian, who for his evening meal was eating a slice of bread and a good-sized apple, remarked—"This, or fruit of some kind, has been my supper from a child, and no man has seen less of the doctor or his medicines than I have." Certainly no one of the age could look better. Some eat daily, as long as they can be had, not less than a pound of strawberries, besides other fruit—and I am glad to know that the habit of eating fruit is rapidly increasing among the higher orders; while our American cousins certainly exceed us as fruit consumers, for there almost anything that has eatable juice in it is pressed into the service. They gloat over a succulent ripe tomato; we most likely should require time to acquire an appreciation of that delicacy. Be that as it may, there can be no question that properly selected fruit is not a luxury, but a necessary of life; and further, the more regularly we use it, the better will it be for us. Well, then, regarding fruit, in its place, to be as much a necessary as bread, the question naturally presents itself, how is the necessary supply to be produced? Already all temperate countries are shorn of their supplies, and still we cry "more, more."

My object is to inquire how more is to be obtained; and looking back to the orchards of the midland and cider counties, and taking into consideration the sackfuls, or even cartloads, of fruit which hundreds of trees individually produce, I ask, is not the dwarfing system, which we have been pursuing for the last quarter of a century, though pretty, so far as it goes, a blunder, as regards the supply of our markets? Fortunately market and commercial growers have not been misled by the pretty deception; they have stuck to the old standard form—guiding, but not restricting, the trees, and they gather fruit accordingly. No scheme has ever led to more disappointment than the pinching and root-pruning systems of cultivation. Such trees make pretty objects in a garden; they are especially pretty when full of fruit, but that is such a rare occurrence as only to be regarded as the exception, not the rule. Such being the fact, it appears that the only sure way to increase our market supplies is to go back to the good old plan of planting orchards, not by scores or hundreds of trees, but by scores or hundreds of acres.

Of the propriety of planting hardy fruits to a large extent there can be no question, so long as the varieties have the qualities of abundant bearing, flavour, and, if necessary, suitability for kitchen use. Take, for example, the Blenheim Orange, Ribston Pippin, Cox's Orange Pippin, and many other apples; they are not only fine dessert fruits, but, once used for a tart, the question soon presents itself from the *chef de cuisine*, Can't we have more? By the same rule, Marie Louise, Beurré Diel, and all the finer dessert pears, are grand for stewing—far superior to the stewing kinds.

I therefore say, plant no inferior fruits, nor any that are not known to be suitable to the locality, unless it be a few odd ones for the sake of trial. Then, even in unfavourable localities for fruit-growing there are certain spots which might be planted with a fair chance of success. Shelter is, of course, a great point; but the shelter of walls is not so good as the shelter of a belt of evergreen trees. On the moors of Yorkshire, for example, or in exposed situations of any kind, where there are no trees to break the force of the wind, a wall is of little more use than no screen at all, for the wind will pass up one side and down the other almost perpendicularly, and bear the plants up at the foot. But with a screen of trees the force is broken, the wind sifted and shorn of its force, and the plants remain comparatively uninjured. Natural shelter should always be taken advantage of when it can be done consistently with other arrangements, and that which protects from the north, north-east, and north-west, is the most desirable. And whatever shelter is provided artificially should be at sufficient distance, so as not to obscure light and sun. Spring frosts are our greatest drawbacks in fruit growing, and therefore the plants when frozen should not be exposed to the morning sun.

These remarks apply more immediately to orchard planting; but still the same rules will obtain in the garden, and the garden will be none the worse for the protection afforded by trees on the exposed sides—and this brings me to that very knotty subject, garden walls. As things of the past, mere protection from the predatory attacks of bipeds, they are well enough. A good wall of peaches, pears, plums, or cherries is a grand sight, but their management is a game of chance, so entirely against the gardener that the question will crop up, is the profit worth the cost? A crop in five years is about the full average from our wall trees, and considering the enormous amount of attention they require, can that be satisfactory or profitable? I think not, at least I confess I am not satisfied, for I think I ought to have more for my trouble.

This, then, brings me to the subject of orchard-houses, and what they are to be. In the formation of a new garden, estimate the cost of walls and of the glass placed against them, and that of building proper houses for the reception of fruit trees of all kinds. Which will be the most profitable investment? While, however, orchard-houses are infinitely superior to walls for fruit culture, let me add that I have no sympathy whatever with the pot culture of hardy fruits. Although I have seen some of the finest crops in the country, I could never see that they could be profitable, the small quantity and inferior quality putting

that out of the question. At the same time, if we look at our old-fashioned peach and other fruit houses, we see plainly enough the result of planting out, and growing what Americans would call true trees. No plant was ever yet dwarfed into what might be called profitable cultivation. The crop may be pleasing enough, very nice from an amateur's point of view, but test it by the gardener's call upon his supplies, or the market grower's return for his produce, and these pot crops sink into insignificance. Proper houses, planted and trained in a proper manner, like our peach-houses or old orchard-houses, must become the most reliable tender fruit-houses of the future. The days for experimenting have passed; the realities of fruit cultivation are perhaps as well known as they ever will be, and certainly they do not favour the pot-growth system. We want, and must have, a positive return for our outlay, and that we shall never get until we allow our indoor fruit trees to develop their full strength, and to take such crops as that strength will carry. If we want to check luxuriance, take the natural remedy of a heavy crop. If we want to augment the strength, reduce the crop below the usual standard. This, I take to be, is the common sense of fruit culture, both present and future.

The Gooseberry as a Pyramid.—Although the naturally low-spreading and spine-guarded gooseberry is rarely seen as a tapering pyramid, it may be grown in that way so as to look much more attractive than in its ordinary state, and its fruit may be gathered, without stooping, as conveniently as that of an espalier pear or apple tree. This, to a lover of the fruit, is some little consideration. We have recently seen a garden with several of its walks bordered by very pretty specimens of erect gooseberries and standard red currant trees alternated, the gooseberries simply tied to a slender iron stake rising about seven feet above the surface of the ground, and pruned so as to gradually diminish from base to top to a mere point. The base of each cone was about fifteen inches in diameter, and the whole perfectly furnished with fruiting spurs. Summer pinching of the shoots is practised to prevent the plants getting out of shape, and also to induce fruitfulness, and they are neatly pruned in winter. The kind best suited to this work is the rough red; it seems to make the handsomest pyramids, and is also a very desirable kind for eating or preserving.

Preserving Grapes in Bottles of Water.—I first tried this plan of keeping grapes on a small scale, in the winter of 1868-69, and succeeded beyond my expectations. During the ensuing summer I therefore had a room specially fitted up for this kind of work; it is twelve feet long and nine feet wide, with three tiers of shelves along two sides and one end, and will hold 130 bottles in all. These bottles have been annually filled since then about the beginning of November with Hamburgs, and all are used by or soon after Christmas. The room is then cleaned, the water changed, and Lady Downe's is then made to occupy the bottles. My experience of four seasons of this mode of treating grapes is, that with half the attention which they require when hanging on the vines, they may be kept perfectly sound; nor does the flavour deteriorate in the least. I exhibited at South Kensington, on March 15th last year, three bunches of Lady Downe's, that had been cut for several weeks; their appearance was all that could be desired, and their flavour excellent. Indeed, my employer, who is no bad judge in such matters, declares that in the matter of flavour there is no deterioration whatever. This year I cut on January 4th more than eighty bunches of Lady Downe's; of these, the last was used on May 23rd, the vines from which they had been cut being then again in full flower. In short, I am so satisfied with the system, especially as regards late grapes, that I last year planted a house, fifty feet long, entirely with Lady Downe's, intending to cut and bottle them about the beginning of each year. This will obviate very early forcing, and secure the possession of grapes all the year round. To those who object to Lady Downe's, I would say ripen thoroughly, and ever afterwards there will be no cause for complaint. The great advantage secured by the bottling system, is, that the vines are at rest, and the house at liberty for plants, which, with the bedding-out mania still in full force, is what we want.—W. WILDSMITH, *Heckfield, Winchfield, Hants.*

Nathaniel Hawthorne on Fruit Trees.—Apple trees and all fruit trees have a domestic character which brings them into relationship with man. They have lost in a great measure the wild nature of the forest tree, and have grown humanised by receiving the care of man, and by contributing to his wants. They have become a part of the family, and their individual characters are as well understood and appreciated as those of the human members. One tree is harsh and crabbed, another mild; one is churlish and illiberal, another exhausts itself with its free-hearted bounties. Even the shapes of apple trees have great individuality, into such strange postures do they put themselves, and thrust their contorted branches so grotesquely in all directions. And when they have stood around a house for many years, and held converse with successive dynasties of occupants, and gladdened their hearts so often in the fruitful autumn, then it would seem almost sacrilege to cut them down.

THE KITCHEN GARDEN.

PRIZE ESSAY ON THE POTATO.

BY GEORGE MAW, F.S.A., G.S., L.S.

(Continued from p. 26.)

EXPERIMENTS ON THE POTATO-CROP.

2. As to the influence on the crop of the distance at which the sets are planted; or the results of close and wide planting of various sized sets.

To establish this point, I shall compare, separately, each series of experiments on potatoes of the same weight, planted at different distances:—

Averages of 1 oz. Sets.

	Gross.			Net.		
	tons.	cwts.	qrs. lbs.	tons.	cwts.	qrs. lbs.
13 varieties, planted 1 foot apart ...	10	9	3 17	9	17	3 0
11 " " 9 inches apart ...	10	12	0 23	9	16	0 0
11 " " 6 inches apart ...	13	4	1 20	12	0	0 13

Averages of 2 oz. Sets.

	Gross.			Net.		
	tons.	cwts.	qrs. lbs.	tons.	cwts.	qrs. lbs.
13 varieties, planted 1 foot apart ...	12	15	2 4	11	11	1 7
12 " " 9 inches apart ...	15	15	2 11	13	10	0 21
10 " " 6 inches apart ...	15	19	0 12	13	10	1 27

Averages of 4 oz. Sets.

	Gross.			Net.		
	tons.	cwts.	qrs. lbs.	tons.	cwts.	qrs. lbs.
12 varieties, planted 1 foot apart ...	15	17	2 15½	13	9	0 2½
16 " " 9 inches apart ...	17	17	3 12	14	13	0 4
3 " " 6 inches apart ...	22	0	2 3	17	3	1 5

Averages of 4 oz. Sets (similar varieties).

	Gross.			Net.		
	tons.	cwts.	qrs. lbs.	tons.	cwts.	qrs. lbs.
3 varieties, planted 1 foot apart ...	15	8	3 24	13	0	1 11
3 " " 9 inches apart ...	15	19	2 14	12	14	3 6
3 " " 6 inches apart ...	22	0	2 3	17	3	1 5

These comparisons all show an advantage in planting the smaller sets at intervals closer than twelve inches in the rows; but the results are not very decided, and in one or two cases the gain in the gross crop does not make up for the extra weight of the sets planted.

The following comparisons refer to the effect of planting the sets more than a foot apart in the rows.

Three experiments averaged together, viz. :—

8 oz. "Flukes," 6 oz. "Flukes," and 4 oz. "Late Red," gave a gross crop of 23 tons 16 cwts. 1 qr. 8 lbs., and a net average of 20 tons 3 cwts. 1 qr. 17 lbs. The same sizes and varieties, planted at intervals in the rows of 1 foot 3 inches, produced a gross crop of 18 tons 13 cwts. 1 qr. 2 lbs., and a net crop of 15 tons 14 cwts. 3 qrs. 20 lbs.—a falling off of 4 tons 8 cwts. 1 qr. 25 lbs. per acre. Indeed the produce of each set was, as nearly as possible, the same, whether planted a foot apart or 15 inches, so that the additional distance was so much loss to the crop. The average produce of 6 oz. and 8 oz. Flukes shows a similar falling off when planted more than a foot apart in the rows:—

	tons.	cwts.	qrs.	lbs.
Flukes, at 1 foot, the net average produce was ...	17	10	1	25 per acre.
Flukes, at 1 foot 3 inches " " ...	15	8	2	6 " "
Flukes, at 1 foot 6 inches " " ...	12	16	0	5 " "

This diminution of the crop, through reducing the number of the sets per acre, is remarkably uniform, and as nearly as possible proportionate to the distance at which the sets are planted.

The general tenor of these experiments points to an interval of ten or twelve inches in the rows, as being the most profitable distance at which to plant large full-sized potatoes, of from four to eight ounces in weight. A moderate increase in the net-crop may be expected from still further diminishing the distance when the sets are below four ounces in weight; but this point will be again referred to in considering

3. The comparative results obtained from planting equal weights of large and small potatoes respectively.

In the previous series of comparisons (1) the advantage of large over small sets, placed at similar distances, was very striking, large sets producing a much greater crop than an equal number of small sets on the same area, and the crop bearing a very regular proportion to the weight of the individual sets. We have now to ascertain whether by diminishing the distance and increasing the number of small sets an equivalent can be obtained for the increased individual productiveness of larger sets.

1 ton 4 cwts. 1 qr. 6 lbs. of sets per acre, planted as—

	Per Acre.		
	tons.	cwts.	qrs. lbs.
2 oz. sets, 1 foot apart, gave, on a number of experiments, a net average produce of ...	11	11	1 7
And as 1 oz. sets, 6 inches apart ...	12	0	0 13

Balance in favour of small sets at close intervals of 0 8 3 6

2 tons 8 cwts. 2 qrs. 13 lbs. weight of sets per acre, averaging a number of experiments, planted—

	Per Acre.		
	tons.	cwts.	qrs. lbs.
As 4 oz. sets, 1 foot apart, produced a net return of ...	13	9	0 2½
As 2 oz. sets, 6 inches apart ...	13	10	1 27

Balance in favour of small sets at close intervals of 0 1 1 24½

4 tons 17 cwts. 26 lbs. planted—

	Per Acre.		
	tons.	cwts.	qrs. lbs.
As 8 oz. sets, 1 foot apart, produced a net return of ...	18	11	0 16
As 4 oz. sets, 6 inches apart ...	17	3	1 5

Balance in favour of large sets at wide intervals of 1 7 3 11

3 tons 4 cwts. 3 qrs. 8 lbs. weight of Fluke sets per acre, planted—

	Per Acre.		
	tons.	cwts.	qrs. lbs.
As 8 oz. sets, 1 foot 6 inches apart, produced a net return of ...	12	3	0 9
As 4 oz. sets, 9 inches apart ...	13	4	2 6

Balance in favour of small sets at close intervals of ... 1 1 1 25

These balances are so small, that they can scarcely be relied on as indicating any decided advantage in either direction; but the nearly equal results of the experiments point conclusively to the fact of the very regular ratio borne between the weights of the crop and the weights per acre of the sets, a ton of sets, whether planted as large or small potatoes, producing the same weight of crop per acre. It must, however, be observed that, *practically*, the principle is only of limited application. Taking 1 foot as the maximum, and 6 inches as the minimum distance between the sets in the rows, it will be easily understood that a weight of small sets, say of 1 or 2 ozs., equivalent to large sets of 6 or 8 ozs., could not be got into the ground, therefore the general principle, that the crop varies as the weight of the sets, weight for weight, is not practically applicable where the sets differ in weight beyond the proportion of 1 to 2. Small sets, therefore, of 1 to 3 ozs., can, under no arrangement, produce as much per acre as sets of from 4 to 8 ozs.

4. As to the relative advantages of cut and whole sets.

A comparison may be instituted between the average results of five experiments with sets formed by dividing large potatoes, and five experiments with old potatoes weighing the same as the cut half sets.

Cut Potatoes.

	Net Balances.		
	tons.	cwts.	qrs. lbs.
Flukes 4 ozs., cut out of 8 oz. potatoes, 1 foot apart, produced ...	12	2	0 23
Flukes 4 ozs., cut out of 8 oz. potatoes, 9 inches apart, produced ...	14	10	2 4
Flukes 2 ozs., cut out of 4 oz. potatoes, 1 foot apart, produced ...	10	4	0 21
Flukes 2 ozs., cut out of 4 oz. potatoes, 9 inches apart, produced ...	11	13	1 12
Flukes 2 ozs., cut out of 4 oz. potatoes, 6 inches apart, produced ...	8	6	2 1
Late Red, 2 ozs., cut out of 4 oz. potatoes, 1 foot apart, produced ...	23	7	1 0
Aggregate on six acres of ...	89	4	0 5
Average per acre ...	13	7	1 10

Whole Potatoes.

	Net Balances.		
	tons.	cwts.	qrs. lbs.
Flukes, 4 oz. sets, 1 foot apart, produced ...	13	3	3 23
Flukes, 4 oz. sets, 9 inches apart, produced ...	13	4	2 6
Flukes, 2 oz. sets, 1 foot apart, produced ...	7	5	0 27
Flukes, 2 oz. sets, 9 inches apart, produced ...	5	12	3 17
Flukes, 2 oz. sets, 6 inches apart, produced ...	7	10	2 23
Late Red, 2 oz. sets, 1 foot apart, produced ...	30	15	2 26½
Aggregate on six acres of ...	77	13	0 10½
Average per acre ...	12	18	3 11

Showing an average balance in favour of the cut sets over an equal weight per acre of whole sets of about 8½ cwts. per acre.

In another instance—

	tons. cwts. qrs. lbs.		
Flukes, 3 oz. sets, cut out of 6 oz. sets, 9 inches apart, gave ...	14	8	1 23
And Flukes, 6 oz., uncut, planted 1 foot 6 inches apart ...	13	9	0 1

Showing a net balance in favour of the cut sets of ... 0 19 1 22

Both these comparative series indicate a slight advantage in favour of the cut sets; but since the individual experiments do not all point in the same direction, the result of the series cannot be looked upon as at all decisive; but it rather tends to the conclusion previously indicated, that the *weight per acre* of the sets planted has more to do with the produce of the crop than any other circumstance.

5. As to the influence of thick and thin planting, and of the size of the set on the proportion borne between the weight of the

sets and their individual produce, and the rate of increase under various conditions.

This subject presents itself under yet another aspect, which interests the physiologist rather than the farmer, viz., the proportion borne between the weight of the sets and the weight of the crop, or, in other words, the rate of increase. This rate, as was to be expected, is larger as the sets are smaller and as the distance is greater, up to one foot apart, beyond which space no perceptible change takes place.

On the general average of these experiments—

The 1 oz. sets increased	14.24 fold
The 2 oz. "	8.77 "
The 4 oz. "	5.87 "
The 6 oz. "	5.81 "
The 8 oz. "	4.83 "
At 1 foot interval, the 1 oz., 2 oz., and 4 oz. sets increased	11.50 "
At 9 inches	9.64 "
At 6 inches	7.73 "

The rate of progression was found to be very regular, both in individual experiments, and in average results.

6. As to the relative productiveness of different varieties of the Potato.

To avoid undue complication, the varieties employed in these experiments have been rather limited, and the question of their relative productiveness has only been a matter of secondary importance. As, however, several of the varieties are very generally cultivated, it may be well briefly to state the results.

The average produce of 1 oz., 2oz., and 4 oz. sets planted 1 foot apart in the rows was as follows on the gross crop per acre:—

	tons.	cwts.	qrs.	lbs.
Late Red	27 10 3 8½
Spencer's King of Flukes	19 13 2 17
Second's Kidney	16 0 3 12
Daintree's Seedling	15 8 1 25
Queen of Flukes	15 3 0 7
Flour-ball	14 2 1 23
"Vite-lots" (French Kidney)	13 6 3 19
Flukes	10 0 1 19
Early Handsworth	6 18 1 23
Early Prolific Kidney	4 14 1 18

The average produce of four series of experiments, viz., 1 oz. and 2 oz. planted at 9-inch intervals, and 1 oz. and 2 oz. at 6 inch intervals, stand in the following order:—

	tons.	cwts.	qrs.	lbs.
Late Red	27 9 1 20½
Spencer's King of Flukes	24 4 2 24
Daintree's Seedling	15 13 0 0
Flour-ball	14 18 3 20
Queen of Flukes	14 15 3 11½
Second's Kidney	14 9 3 3
Lapstones	11 4 3 5
Early Handsworth	7 14 2 17
Flukes	7 6 0 3
Lemon Kidney	7 4 1 20
Early Prolific Kidney	6 12 2 18

The crops produced from 6 oz. sets planted 1 foot apart, stand in the following order of productiveness:—

	tons.	cwts.	qrs.	lbs.
Late Red	37 18 3 0
Spencer's King of Flukes	30 19 3 12
Second's Kidney	26 8 2 22
Daintree's Seedling	25 16 2 5
Flukes	22 1 0 21
Early Handsworth	13 16 2 0
"Vite-lots" (French Kidney)	13 8 1 8
Lapstones	11 19 0 3
Early Prolific Kidney	7 9 3 17

Of "The Queen of Flukes" and "Flour-ball," there were no experiments with 6 oz. sets.

The relative productiveness of the several varieties grown from 8 oz. sets, planted at intervals of 12 inches, stand thus:—

	tons.	cwts.	qrs.	lbs.
Late Red	38 19 2 25
Spencer's King of Flukes	34 0 2 14
Queen of Flukes	30 5 2 9
Flukes	21 9 3 19
Lapstones	4 17 0 26
Early Prolific Kidney	3 15 1 11

The above four series of comparisons are tolerably uniform, as expressing the relative productiveness of the varieties they include. The actual order of precedence of some of the individual varieties, that do not differ much in their produce, varies a little; but the relative positions are in general uniform; the late red in each set of experiments produced the heaviest crop; and the Early Prolific Kidney appears in every case at the bottom of the list.

Of the three varieties of Fluke, the greater productiveness of both Spencer's King and the Queen of Flukes, than that of the ordinary variety, is very noticeable; Spencer's King especially, throughout the series, producing from half as much more to twice as much as the Common Fluke, not only in the general averages, but in all the individual experiments.

(To be continued.)

The Culture of Spinach.—To Mr. Barnes's admirable article on this subject I should like to append a caution about New Zealand spinach. Certainly it is not to be compared for tenderness and sweetness with the common round spinach, and in some establishments the New Zealand will not be eaten at all. Where it is liked it is, however, a great boon to the gardener, as the warmer and drier the weather the faster it grows, affording any number of pickings without fear of exhaustion or bolting. The spinach Beet is likewise an acquired taste, somewhat different from that of common spinach, but often preferred, when the taste gets accustomed to it. No one, however, need be without spinach all the year round who are careful to carry out the full and practical instructions set forth by Mr. Barnes at page 40, vol. ii. Perhaps no vegetable suffers or gains more in the cooking and dressing than spinach, and the reason why it is not more popular in small gardens, is doubtless that it is mostly badly cooked and served. Perhaps some of the *chefs* of the kitchen will kindly report on a few of the best methods of preparing spinach for table.—D. T. F.

Advertising Cabbage Seeds.—The description which you have given in THE GARDEN (p. 26, vol. ii.) of a French banker betting to raise a large sum by liberally advertising cabbage seed of a mammoth-headed variety, has been rivalled in this country. Some thirty-six or thirty-seven years ago, a Cesarean cow cabbage was advertised to be sent out from a shop in London, at the modest price of one shilling per seed. This cabbage was described as growing to the size of a little tree; and the sale of the seeds, from being advertised in all the newspapers of the day, must have brought in a large sum to the fortunate vender. When I first came to Welbeck I was surprised to see this so-called monstrous cabbage growing in quantities in pots in the greenhouse, and my predecessor had likewise struck a quantity of cuttings from the plants, on purpose to have as many as possible to plant out in the spring, as they were expected to keep a large dairy of milk cows in green food in the winter. The result was, after all the expense of the seed, and trouble in cultivating the plants, that this mammoth cabbage turned out to be the Jersey cow cabbage, the sort of the branches of which they make walking-sticks in that island. The demand for this cabbage seed was so great when it was first advertised that the stock soon got exhausted, and to send a few seeds of it in a letter to friends at a distance was considered a real service.—WILLIAM TILLERY.

Killing Weeds on Walks (see p. 598).—At this place we have about a mile of gravel walks which had been "hand-picked" for several years, the consequence was, the gravel never set into a hard even surface, and of course was never pleasant to walk upon. Weeds, too, never grow upon a solid walk so plentifully as upon a loose one; we therefore gave up hand-picking, and applied clean agricultural salt for two seasons. The result is, not a weed in a hundred yards; the walks are hard and smooth, and never looked so well before. I admit that sometimes the grass at the edges suffers, but this is owing to heavy rains dashing the salt on to the grass. This may be remedied by taking a fine rosed watering pot and just dissolving the salt with water near the edges of the walks. The cost of salt is not near so much as that of hand-picking.—DAVID WALKER, *Dunortan, Tunbridge Wells.*

PUBLIC GARDENS.

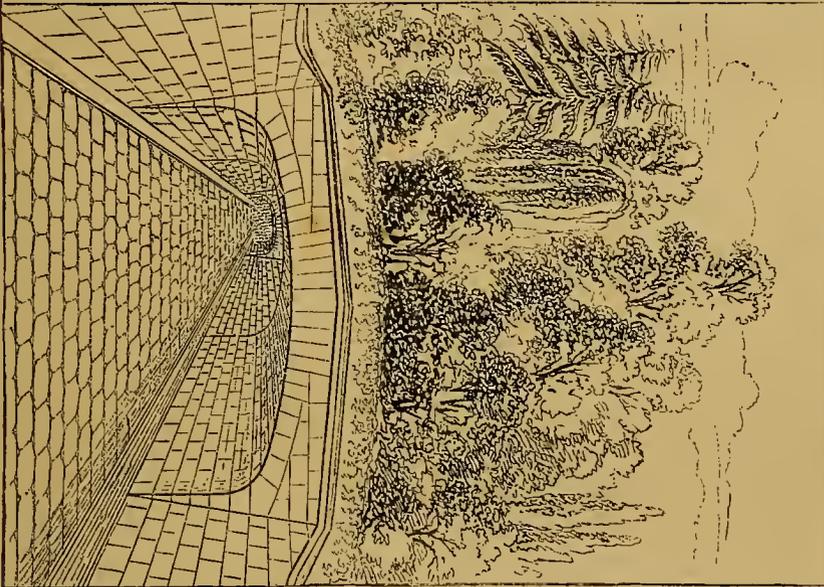

THE CENTRAL PARK, NEW YORK.

WE this week terminate our notices of this noble park, by giving its plan on a very much reduced scale, in consequence of the peculiar shape of the park; a view of one of the transverse roads which pass under the park from one side to the other; a plan of one of the rocky lawns, which we thought such attractive features; and also one of the chief pieces of artificial water, and of the boldly-designed main entrance. The transverse roads are particularly worthy of notice as a good contrivance to prevent the quiet of the park being destroyed by traffic. The many tortuous walks near the lake are those of the "Ramble," a densely-wooded and wild plantation, full of wild flowers in spring and early summer. The want of openness shown in it is the result of design, and good design. The fine broad character of one of the main entrances and its surroundings will be seen from our engraving in another page.

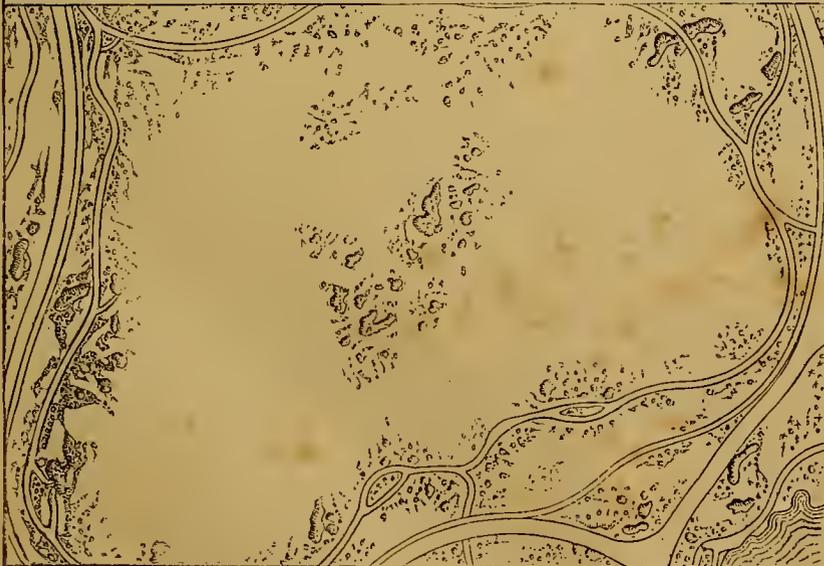

It is necessary to point out that the formal outlines of the great reservoirs which supply the city were one of the many difficulties which had to be overcome by the designer. They as yet disfigure the plan, but the park and its drives and walks are so disposed that the reservoirs are not an eyesore to the visitor. We trust and believe that this noble park is but an example of what every great city in America will one day possess.

KEW GARDENS.

MR. AYRTON AND DR. HOOKER.

A LEARNED judge once likened a brother on the bench who was remarkable for the rude energy with which he tore through his work, to a rhinoceros in a sugar plantation. There would appear to be a good deal of the rhinoceros in Mr. Ayrton's style of doing business. From the glimpses we get of him in the course of the official controversies in which he is perpetually embroiled, he would seem to be always rushing about madly, tearing up the ground with his horn, dashing himself against trees and palisades, and occasionally, by way of personal diversion, ripping up some unfortunate man of art or science who has got in his way. In the last year or two we have had more than one opportunity of seeing the "Noble Savage" on the rampage, but the spectacle, though enlivening perhaps for those who like these exhibitions of wild fury, is not exactly a pleasant one. It is an unequal contest to begin with. The victims chosen for attack have clearly no chance in an encounter with their hard-borned, pachydermatous assailant. They have feelings, and he has none. They are poor sensitive creatures who wince under any disparagement of their profession as much as under personal insult; and they are doubly outraged when their art and themselves are simultaneously degraded. It may be a nice question why architects, artists, and people of that sort should consider themselves gentlemen, and expect to be treated as such; but they have at least been accustomed to this treatment; and the first shock of being addressed in the fashion in which a navy "ganger" usually communicates with his subordinates is apt to be too much for them. The Chief Commissioner is protected by the consciousness of his own moral superiority against whatever remonstrance or reprobation may be excited by his conduct. It is true his victims might meet him with his own weapons. They might address him in the same style as that in which he addresses others; but even if he were sensitive to this kind of retaliation, he is preserved from it by the self-respect of his antagonists. It would appear that Mr. Ayrton has made it his mission to put down artistic and scientific pretensions. He loses no opportunity of screwing, brow-beating, and bullying architects, painters, sculptors, and gardeners, and making them know their proper places. Last year he was running a-muck among the architects. Now it is the turn of the gardeners. A curious story is told in a memorial which has just been addressed to the First Lord of the Treasury complaining of the usage to which Dr. Hooker, the Director of Kew Gardens, has been subjected by Mr. Ayrton. It is possible that there may be some misapprehension as to the facts of the case, and official explanations, when we get them, may throw new light upon it. But the statements in the memorial appear to be based on official correspondence, and the names which are attached to it, including those of Sir Charles Lyell, Mr. Charles Darwin, Sir James Paget, Professors Huxley and Tyndall, and the Presidents of the Royal Institution, the College of Physicians, the College of Surgeons, and the Geographical and Linnæan Societies, invest it with authority. It can scarcely be necessary to remark that one story is good until another is told, and that the memorial gives us only one side of the controversy between the First Commissioner and Dr. Hooker. We have yet to learn what Mr. Ayrton has to say for himself, and it is possible that on some of the points which have been raised there is room for argument. But the argument must not be allowed to take too wide a range. Whether it is or is not desirable that Dr. Hooker should exercise supreme and undivided authority over the establishments at Kew is a question which may be conveniently postponed. The most serious part of the accusation against Mr. Ayrton is, as it seems to us, not that he superseded Dr. Hooker in some of the duties he had previously discharged as director, but that he superseded him in a grossly offensive and insulting manner, without complaint and without notice, so that Dr. Hooker had not only no opportunity of justifying himself, but was left to discover his supersession casually from one of his own subordinates. We have here a simple question of fact, as to which there should be no beating about the bush. Either Dr. Hooker was superseded in the way he alleges, or he was not. If he was not, he must be the victim of an extraordinary hallucination; if he was, there can only be one opinion as to the First Commissioner's conduct. It is intolerable that the head of a great public department should be exposed to this kind of petty spitefulness and boorish insolence. We hope that Mr. Ayrton will be able to refute the charge, but it is impossible not to have a painful recollection of other incidents of a too similar kind which have distinguished his not very glorious career at the Board of Works. We have no desire to re-open the Barry controversy, but it will be remembered as a conspicuous example of our Edile's unhappy manners, or rather want of manners. There is a kind of surly gruffness which in the vulgar mind is apt to be associated with honesty, if not deemed an indispensable ingredient of it. Mr. Ayrton

perhaps aspires to be known in history as "Honest Ayrton," and if rudeness and honesty are synonymous he may be acknowledged to have fairly earned the coveted appellation. It is obvious that a man must be of a very superior moral constitution to his fellows when he disdains the weak dissimulation of calling a vault a crypt, and exercises his ingenuity in inventing impertinent answers to the simplest questions which are addressed to him on matters of business in the House of Commons. Should the statements in the memorial prove to be correct—and, as we have said, nothing can be easier than to ascertain this—it will be the duty of the House of Commons, if the Government declines to take the initiative, to make Mr. Ayrton understand in some very sharp and decisive manner that it is not part of the duty of a Parliamentary official to treat the permanent advisers of his department with "personal contumely" and studied insult, and to neutralise their efforts by intriguing against them behind their backs, and inciting their subordinates to disregard their authority. Every one must admire the indomitable austerity and persistent insolence of Mr. Ayrton's demeanour, on which the softening influences of official life have produced no effect whatever; but perhaps this kind of heroism will be more admirable elsewhere than on the Treasury bench.—*Saturday Review*.—[Lord Derby has, we see, given notice that he will bring this matter before the House of Lords next Monday.]

THE INDOOR GARDEN.

CAPE HEATHS AND THEIR CULTURE.

A COLLECTION of heaths is always about the last addition that is made to any establishment, when they are favoured with a place at all; but it is seldom they are, either in the form of a collection or as an addition to the decorative portion of conservatory plants. And yet it is not denied that the beauty and loveliness of some of the varieties, not to speak of their great usefulness as pot plants and for cutting, more than surpasses many of the most popular greenhouse plants now in cultivation. An impression exists in the minds of many that they are difficult to manage, and no doubt this is one reason why the heath does not enter more largely into the ordinary conservatory stock. Where large collections are kept as a matter of convenience, they generally receive the special attention they require; but there is nothing at all difficult or particular about their culture to deter anyone from growing a few of the best spring and autumn flowering varieties, according to their requirements, more than the *cucuraria*, the *fuchsia*, or the *chrysanthemum*, and many other things that are considered indispensable for the conservatory. I shall name a few of the most useful kinds; but those who contemplate adding a collection of heaths to their stock would do well to visit some good nursery in their neighbourhood at different seasons of the year, but particularly in the autumn, winter, and spring months, and select for themselves, when the plants are in flower, the varieties likely to suit their purpose. Small, useful plants, furnished with flowers, are now to be had cheap—cheaper, indeed, than many of the common bedding plants and other things that glut the market nowadays. What are called soft-wooded heaths are the easiest cultivated, and amongst them are to be found the gayest and most useful kinds. *Erica hyemalis* is one of the best known and most popular kinds; it throws up its graceful pyramidal flower spikes in abundance, never fails to flower, and with a little management may be had in bloom from January to June. Something like *hyemalis*, but of a more slender habit, and with flowers of a more delicate tint, is *E. Willmoreana*, which should be in every collection. Then there are *E. gracilis*, *Cavendishii*, *colorans*, *florida*, and all the *ventricosa* class, which are not surpassed by any variety for freedom of habit and showiness. These are all soft-wooded kinds, and amongst the best of that class, and will in themselves afford a display for six months. Of hard-wooded varieties, *E. aristata*, *aristata major*, *Marnockiana*, *Aitoniana*, *Aitoniana Turnbullii*, *ampullacea major*, *Bowieana*, *vestita alba*, *v. coccinea*, *v. rosea*, *v. elegans*, are good and well-known kinds, blooming mostly after midsummer and in autumn: but all the hard-wooded varieties require more attention than the others, and they are more formal in habit, and less accommodating for cutting and furnishing, than the others. Therefore, except where a collection is the object, we do not counsel anyone to invest largely in them.

It is, I think, unnecessary to say anything about the propagation of the heath. Amateurs seldom raise their own stock, for it is cheaper to buy established plants. Supposing, therefore, that we have got a lot of plants in four and five inch pots to begin with, that are generally getting out of bloom about the beginning of summer, or later, they should, in the case of such kinds as *hyemalis*, *gracilis*,

Willmoreana, ventricosa, and all such free-growing kinds, be shorn clean over with a pair of shears, clearing away entirely all straggling growths, and reducing the plants to something like symmetry. If the plants appear pot-bound, they will also require a shift at this stage. The best soil for the heath is good pure peat; if it does not naturally contain sand, it should be mixed with about one-quarter of its bulk of good silver sand. A pot that will allow about half an inch of fresh soil round the ball of the plant will be large enough in the case of moderate-sized plants, at least; and the pots must be well drained with an inch or two of clean crocks, which must be covered with a layer of moss, to prevent the soil working down among them and choking them. In potting, turn the plants carefully out of the pot, remove the old crocks, clean the surface of the ball, and loosen the matted roots

The space will serve as a kind of measure, and save repeated and frequent waterings, and prevent uncertainty in the matter. After the plants have been potted they should be plunged in ashes in a cold frame; there is no place better for them than this, and the frame should be set facing the north, and the plants must be shaded from the hot sun with a thin shading. Care in watering will also be necessary at all times, so that the roots are never allowed to get too dry, nor get wet, and liberal dewings in the afternoons, during hot weather, will be highly beneficial; but nothing like shutting up or forcing must be practised with them. Shading may be gradually discontinued, and more air given, till at the end of two or three weeks the lights may be taken off the frame altogether for the season. All soft-wooded heaths succeed best in every way when grown out of doors in summer.

One of the Entrances to the Central Park, New York.

around the sides carefully with the point of a label. This is an operation that must be performed fearlessly if the roots are much matted, so as to liberate them entirely. It is of little or no use potting a plant in a pot-bound condition, as it will be long before it takes to the fresh soil, which will part from the ball years after if taken out of the pot, leaving it much in the same condition it was when first potted. When the plant is ready for the pot, put as much soil into the latter as (when beaten pretty hard) will raise the surface of the ball to within from $\frac{1}{2}$ inch to 2 inches from the rim of pot; then fill in round the sides with the compost, and ram firmly with the broad end of a label, as the work proceeds, until the pot is filled up level with the surface of the ball. The advantage of keeping the surface of the soil an inch or more below the rim of the pot will be discovered when the plants have to be watered frequently in dry weather.

This is a well-established fact, and the frame treatment is only recommended for a short while with newly potted plants. The plants should be housed some time in September, or before frost catches them. They should have the lightest, airiest, and driest place in the conservatory, and during winter and spring they will more than repay the attention bestowed upon them. The hard-wooded kinds require exactly the same treatment as the soft-wooded ones, only that they must not be cut back; and they succeed better when grown indoors all the year round. Mildew is the only evil to be feared in the way of parasites, and is very destructive to the foliage when it gets the mastery; but timely dustings with flowers of sulphur will always arrest its progress. It is not to be feared, however, except in a close and muggy atmosphere. In conclusion, I would state that the clipping over after flowering of the

soft-wooded heaths, as I have recommended, is not absolutely necessary, nor always practised; but it is the way to secure a well-furnished plant, plenty of bloom, and it saves staking, which should never be tolerated except in the case of some of the straggling hard-wooded varieties.—J. S. W., in "Field."

A REVISION OF THE GENUS DRACÆNA.

BY DR. REGEL.

(Concluded from p. 33.)

DOUBTFUL SPECIES.

<i>Dracæna acuminata</i> (Thbg.)	<i>Dracæna hemichrysa</i> (Thbg.)

Fuchsia Avalanche.—Two double-flowering Fuchsias bear this name—the one having a carmine tube and sepals and a dark plum-violet corolla; the other having a bright scarlet tube and sepals and a white corolla. Of the first of these some capital specimens may be seen at the gardens of the Royal Horticultural Society, at Chiswick; the foliage has quite a yellow tint, and the habit of the plant is very elegant, the branches drooping gracefully—this characteristic, in all probability suggested the name "avalanche." The flowers are very large and of fine form, and, whether used as an exhibition plant or for the purposes of house decoration, it cannot fail to be much regarded. It appears, also, to be a good free-blooming variety.—R. D.

THE HOUSEHOLD.

THE HEDGEHOG (OR SPINE-BEARING) MUSHROOM.

(HYDNUM REPANDUM.)

THERE is no possibility of mistaking this mushroom: when once seen it is always to be remembered. Its awl-shaped spines are crowded beneath the pileus; its size and colour are most marked; it resembles closely a lightly-baked cracknel biscuit in colour. "This fungus," says Badham, "occurs principally in woods, and especially in those of pine and oak; sometimes solitary, but more frequently in company and in rings."

Pileus smooth, irregular in shape, depressed in centre, more or less lobed, and generally placed irregularly on the stem

Spine-bearing Mushroom (*Hydnum repandum*). Woods, autumn; colour, pale buff; diameter, 2 to 5 inches.

(eccentric); of a pale buff or cinnamon colour; from two to five inches in diameter. Flesh firm and white; when bruised it turns slightly brown. Spines crowded, awl-shaped, slanting, soft, and brittle, varying in size and length, and of a faint cinnamon tint. Stem white, short, solid, crooked, and often lateral.

Opinions on the Merits of *Hydnum repandum* as an Edible Fungus.

"When well stewed it is an excellent dish, with a slight flavour of oysters. It makes also a very good *purée*."—*Dr. Badham*.

"A most excellent fungus, but it requires a little caution in preparation for the table. It should be previously steeped in hot water and well drained in a cloth; in which case there is certainly not a more excellent fungus."—*Berkeley*.

"A wholesome fungus and not to be despised; but not in the first class as to flavour, requiring the help of condiments. It has the advantage, however, of growing later than most funguses, and may be found up to the middle of November."—*Edwin Lees*.

"One of the most excellent fungi that grows; its flavour very strongly resembles oysters."—*Rev. W. Houghton*.

Modes of Cooking *Hydnum repandum*.

The hedgehog mushroom is dense in structure, and in whatever way it may be cooked, all authorities agree that it must be done slowly at a low temperature until it is tender, and with plenty of stock or white sauce to supply its deficiency in moisture.

Stewed *Hydnum*.—"Cut the mushroom in pieces and steep for twenty minutes in warm water; then place in a pan with butter, pepper, salt, and parsley; add beef or other gravy, and simmer for an hour."—*Trans. from M. Roques*.

"Stew in a brown or white sauce."—*Mrs. Hussey*.

"Cut up in bits about the size of a bean, and stew in white sauce, when it will almost pass off as oyster sauce."—*Rev. W. Houghton, F.L.S.*

HARDY PLANTS IN FLOWER ROUND LONDON.

— GREEN APRICOTS, about the size of glass marbles, sell, it is reported, in the market at the African diamond fields for eight shillings per hundred.

— THE beautiful sheet of water and waterfall at Astle Park, Chelford, Cheshire, last week, were entirely swept away by a flood, the foundations having been previously injured by a storm of the 19th June.

— ACANTHOLIMON VENUSTUM, a rare plant of the Thrift family, is at present in flower in the Royal Gardens at Kew. It produces a longer spike of bloom than the well-known *A. glumaceum*, and has flowers of a deeper shade of rose.

— ON Saturday afternoon last the Marquis and Marchioness of Westminster entertained about 800 guests at a garden fête in the beautiful grounds at Cliveden, near Maidenhead, upon the occasion of the twentieth anniversary of their wedding-day.

— THE beautiful Himalayan *Cyananthus lobatus* is now in flower at the Exotic Nurseries, Tooting; where also may be seen blooming the rare *Hypericum nummularium*, a dwarf species about three inches high, which produces a profusion of yellow flowers.

— THE cotton plants in the hothouse near the entrance to the International Exhibition from Prince Albert Road, are ripening their seeds, and disclose the fleecy pods of cotton, which are the successors to the yellow flowers of the plant; and the growth of some twenty Egyptian, American, and Indian varieties may be examined.

— NORTHUMBERLAND HOUSE is about to come down, and a new street from Charing Cross to the Thames Embankment is to take its place. This certainly will be an improvement, and one long needed. In purchasing the privilege of removing this structure, the Metropolitan Board of Works will have to hand over to the Duke of Northumberland the sum of £489,500.

— AT Messrs. Veitch's nursery at Chelsea, the beautiful *Cianthus Dampieri*, planted out on a piece of rockwork in the open air, is in a most flourishing condition, and producing flower-spikes freely. This plant treated as a tender annual, and planted out in the end of June, is one of the finest objects imaginable, though seldom seen growing out of doors in England.

— AMONG the most beautiful plants in Covent Garden now are neat specimens of *Rhodanthe Manglesii*, which, we are glad to see, has become very popular as a market plant this season. The plants in Covent Garden are from spring-sown seeds; but the best way to raise fine specimens is to sow in August or September, and to grow the plants on through the winter in a cool airy hoase.

— THE Epping Forest Commissioners met the other day and immediately afterwards proceeded to perambulate the boundaries of such portions of the unenclosed waste lauds and inclosures as are within, or in the vicinity of, the manors of Epping, Nazing, and Theydon Bois. This perambulation was made for the purposes of the Epping Forest Act of 1871.

— THE orchards in Surrey and adjoining counties present an unfavourable appearance this summer. Many apple trees are quite without fruit, and others will produce a short crop. Pears make a better show, although the crops are partial. Carrants are scarce, especially red and white. Damson trees at present look promising for a yield of fruit, and there is a good show of nuts and filberts.

— ON Monday last the Society for Promoting the Culture of Flowers among the Poor of Lambeth, of which the Archbishop of Canterbury is president, held its second annual flower show in the grounds of Lambeth Palace. The show was a great advance upon its predecessor, and the various districts of St. Philip, St. Mary, St. Mary-the-Less, St. Anne, and St. Peter's, Vauxhall, were well represented. The Archbishop visited the show during the day, and expressed his approbation. In the evening the prizes were distributed by Mrs. Tate. The gardens adjoining the Palace were also thrown open, and enlivened by means of a band of music.

— THERE is now in flower at Slough, round about and over the top of a little cottage-door, a mass of a large, bright purple-flowered *Clematis* (*C. Jackmanni*), which forms a display as gorgeous as any that the gardens, or even the hothouses, of the wealthy can show. The flowers, many of them four inches across, are so profuse, and form such a mass of dazzling purple, that the plant is distinguishable two or three hundred yards off. Going by the down train, the cottage is in the first road to the left on leaving the station. It is worth a flower-lover's express pilgrimage to Slough, to have the privilege of looking at it for five minutes, and then returning; just as the enthusiastic Spaniard, in the reign of Augustus, travelled to Rome only to look upon the great historian Livy, and having seen him went straight hack to Spain, without giving a passing thought to other matters, not even to the splendours of the splendid capital of the world.

NOTES OF THE WEEK.

— A BEAUTIFULLY variegated form of *Sibthorpia enropæa* has been found in Scotland, and will shortly be sent out from a London nursery. It is quite a gem in its way.

— CONSPICUOUS among herbaceous plants in flower round London at the present time, may be noticed dense masses of the fine *Alstroemeria aurea*, which is flowering very freely this season. It is a plant that should be in all collections of hardy border plants.

— THE fruit of ten orchards in Clydesdale was sold in Glasgow a few days ago, and brought £614, as compared with £326 realised for the same orchards last year. So that in that district at least we may presume there has not been such marked destruction from late frosts as in the southern parts of the country.

— ONE of the most beautiful of the outlying portions of Wimbleton Common is doomed. "Caesar's Camp" has been sold for building purposes; a fence has been already erected halfway across it, and there is every prospect of "eligible villa residences" being seen there in a few months, unless some action be taken with a view to securing it to the public.

— MUCH excitement prevails in Penzance, and the districts of West Cornwall which supply the metropolitan and midland markets with early vegetables, in consequence of a demand by the Vicar of Gulval for a re-valuation of the tithe rent-charge in his parish, on the ground that agricultural land has been converted into market gardens since the tithe commutation. The legality of his application for a new assessment is disputed, and will probably have to be settled at law; but it is strongly urged that if it should be established, Parliament should be invoked to prevent—subject to the vested interests of existing incumbents—the interference with the development of the use of land which would arise from the possible repetition of similar claims.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL-REPORTER.

PRIVATE GARDENS.

Indoor Plant Department.—Conservatories are now gay with Balsams, which are liberally supplied with manure-water; in order to secure a succession of blooming plants, some have all their flower-buds removed until about four to six weeks before they are required for use. Young Fuchsias now play an important part in these structures, as do also older plants of them trained to rafters in the form of climbers, which, if well attended to, as regards thinning and watering, their blooming season will be considerably prolonged. It is considered a bad practice to thin out too much of the wood at any one time; on the contrary, they should be gone over frequently, and as they always emit flower-buds at the joints as they advance in growth, shoots that attain too great a length are removed, giving such as remain a better chance to furnish fine flowers. Pelargoniums are now mostly done flowering, with the exception of zonal kinds, which are encouraged. Several annuals, from April and May sowings, are now in full bloom; others are coming on, and a few are being sown for later use. Coleuses are at present very effective; these are always best when produced from early spring cuttings; a few old plants only are retained through the winter, in order to furnish cuttings late in February and March. Coleuses, when bushy and well-grown, make charming vase plants, edged with *Tropæolums*, ivy-leaved *Geraniums*, *Æschynanthuses*, *Hoyas*, *Convolvulus mauritanicus*, variegated *Panicum*, &c. Among the best kinds of Coleus are Queen Victoria, Duke of Edinburgh, Princess Royal, Marshallii, Bausii, Prince Arthur, Beauty of St. John's Wood, Golden Gem, Hector, Wilsonii, Reevesii, and Telfordii aureus. *Plumbago capensis* is at present one of our finest greenhouse plants, both in the form of a specimen, and as a climber. Camellias planted in borders are daily syringed in warm weather. In order to give a little floral relief, pots of Japan Lilies, such as speciosum, roseum, and punctatum, are placed here and there among the *Acacias*, *Camellias*, &c., with excellent effect. These Lilies are top-dressed with rough lumpy loam and manure. Lilies in pots that have done blooming are laid on their sides against a wall or fence, in such a manner as to prevent rain from reaching them. Specimen Azaleas should, if possible, have a house to themselves, in which they can be placed near the glass. Hard-wooded greenhouse plants, such as *Heaths*, *Epacrises*, and many others, are now set out of doors on beds of ashes, and are carefully watered; the ground about them is also well saturated at least twice a day in bright weather. In stoves, *Allamandas*, *Bougainvilleas*, *Clerodendrons*, and *Stephanotis* are blooming freely, and when allowed to ramble over a trellis on the roof they have a much finer appearance than when trained on pot trellises, as seen at exhibitions. Stoves at this season are not generally very gay, the principal flowering plants in them being *Ixoras*, *Gloxinias*, *Gloriosas*, *Gesneras*, *Strelitzias*, and a few others. *Marantas* growing freely, if likely to become pot-bound, should be again repotted; plants of *Cyanophyllum magnificum* when growing freely, are likewise shifted a second time, using for the purpose good yellow loam, a little peat, decayed hot-bed manure, and white sand. *Caladiums* are being tied and trained rather openly, so as to permit of the free development of the young leaves. *Sonerilas*, *Bertolonias*, and similar fine-leaved plants are much more highly coloured when grown under bell-glasses perforated at the top, and otherwise treated like *Anæctochiluses*, than when grown in pots unprotected. As regards *Orchids*, *Cypripediums*, *Odontoglossums*, *Oncidiums*, and *Stanhopeas*, continue to afford occasional spikes of bloom. *Lælias*, *Cattleyas*, &c., are not allowed to get too damp. Air is freely admitted to the cool houses, and any plants growing freely, if necessary are top-dressed or repotted.

Flower Garden and Shrubbery.—Pruning of hedges, and also the shortening in of straggling branches of evergreens, are still being proceeded with. In the case of contending leaders, one is removed. The principal work in the flower garden now consists in hoeing, raking, and mowing and rolling. *Verbenas* and *Petunias* are being pegged down in such a way as to cover the ground. At the base of *Calceolarias*, little basins are formed for the retention of water, which is liberally given in the evenings. In what is commonly known as "carpet bedding," *i.e.*, beds composed of golden *Feverfew*, *Alternantheras*, *Antennarias*, and similar dwarf-growing plants, the pattern or designs are accurately preserved by removing any branchlets or leaves likely to obliterate or otherwise impair their shape. *Hollyhocks* from spring seedlings are again transplanted into deeply-worked, well-manured borders, such as those now empty by the removal of early *Cauliflowers*, *Potatoes*, or other vegetables. Cuttings of *Tea* and *China Roses* are inserted in wall

borders, and are covered with hand-lights. Budding of *Roses* is likewise being carried on. *Wallflowers*, such as *Marshallii* and some of the double sorts, are being increased by means of cuttings inserted in wall borders, prepared with a good dressing of leaf-mould and sand.

Indoor Fruit Department.—In early pineries, in which the fruit has been cut, the plunging or fermenting material is being turned out, and the pits thoroughly cleansed and lime-washed. Suckers are being firmly potted into six-inch pots, using for them fibry loam and a little charcoal; after being potted they are either plunged in front of late succession plants or in separate beds, and shaded for a short time during bright sunshine. Vines swelling fruit are allowed abundance of moisture, both at the root and in the atmosphere. Late vine borders receive good soakings of manure water, either from the farmyard or the cesspool, occasionally; immediately after the manure water has been applied, another soaking of pure water is given, in order to dilute the first application, and to wash it down. Figs are now producing a second crop, and in every instance this crop seems unexceptionally fine. They are allowed abundance of moisture at the root, overhead, and in the atmosphere. Stimulants are not often applied to Figs in the way of manure water, but a mulching of good fibry loam and rotten manure they thoroughly enjoy. Peach and Nectarine trees done fruiting are well syringed and supplied with water; they are also freely exposed to the air. Melons done fruiting are either thrown away and replaced by young ones, or cut back and encouraged to start anew; but young plants are best.

Hardy Fruit and Kitchen Garden.—Fruit trees on walls have their shoots gradually reduced, and those that are left tied in. In the case of Pears, Apples, Plums, and Cherries, where several shoots spring from one spur, they are all removed, except one or two, which are shortened back to within six inches or so of the base. This is not the case, however, with Morello Cherries, which always bear their fruit on the young wood, which is therefore preserved as much as possible, removing only weak and worthless shoots. Young Peach and Nectarine trees in pots, and also Figs, are now plunged outdoors in warm sunny positions; their pots are not covered over, but they are kept so that they can receive abundance of water. Plums in pots are treated in a similar way, and besides those not bearing fruit, those that are yielding a crop, are also turned out, with a view to improve the fruit. Strawberry runners for forcing are being pegged into three-inch pots sunk in the soil; they are stopped at the joint beyond that to be taken off. Runners for new plantations are also stopped when two or three of the joints have struck root. Rows of Peas are being staked and earthed up. The main winter crop of Turnips is thinned, and a successional crop of Radishes is being sown. A few early Kidney Potatoes are being planted, in order to have some young ones in early winter. Potato Onions are taken up and dried. A few Early Horn Carrots are being sown for drawing young. Of Purslane, a late crop is being sown. Salsafy and Scorzonera are being thinned, and their flower spikes removed. Of early Cabbages, a few are being sown for autumn planting, and in late localities the main crop is being sown. Savoys, Brussels Sprouts, and white and Sprouting Broccoli, are being earthed up, and all spaces that are empty, are being planted, giving them at the same time a good watering. Lettuces are being transplanted as required, and small salads are sown frequently. Vegetable Marrows are abundantly watered, and the shoots as they advance in growth are pegged down, so as to cause them to root at the joints.

NURSERIES.

Indoor Department.—Stove and greenhouse plants are now making good growth, and such as are forward enough, are encouraged to ripen their young wood by placing them in cooler and more airy quarters. Young plants of *Allamandas*, *Dipladenias*, *Bougainvilleas*, *Jasminums*, *Thubergias*, *Ipomeas*, *Passifloras*, and others are being repotted, using for the purpose, good rough loam, leaf mould, and a little white sand; to the *Allamandas* and *Jasminums* some add a little peat. After being potted they are tied to stakes, placed rather closely together in a house or pit, and kept a little close for a time. Young *Rhododendrons* and *Azaleas* are being top-dressed, removing half an inch of the surface mould, then dusting on a little of Standing's manure, afterwards filling up with good peat and white sand; some firms mix a little of the manure with the mould, whilst others just sprinkle a dusting between the old and new soils. Young plants of *Lapageria rosea* are also similarly treated. *Callicarpa purpurea* is being repotted, using two parts peat, one loam, and a good admixture of sand. Young plants of *Vitis antarctica* are also being repotted; this is one of the best vines for town conservatories. *Begonias* are set very thickly on shelves, and such sorts as *Weltoniensis*, *spathulata*, *hybrida floribunda*, and *Sandersii* are gently

syringed twice every warm day. Some are being forwarded for blooming, whilst others are just cut over so as to induce them to come in succession. The herbaceous kinds, such as *B. Boliviensis*, *intermedia*, *Sedenii*, &c., are placed on inverted pots near the glass, and are liberally encouraged to make growth; they are also being increased by means of cuttings. *Bouvardias* are well pinched, and kept in an intermediate house, where they are starting freely. *Cyclamens* are arranged together quite closely on shelves near the glass in cool houses; they are not kept quite dry, but receive regularly a little water, so as to preserve the bulbs from shrivelling. *Dracaenas* are being cut down, and the stems cut into pieces, from two to eight or nine inches in length, which are inserted in the cocoa-nut fibre, and, as young shoots spring from the individual eyes, they are taken off singly with a heel, and treated as cuttings. *Pandanuses* are increased by means of the shoots that issue from the base of the large plants; these are taken off with a heel, and are inserted in the plunging material until they begin to push out rootlets, when they are taken out and potted singly. From incisions formed on stems of *P. Veitchii*, that had been thus stripped about two months ago, another progeny even more numerous than that previously taken off, is being produced. *Ficuses* are being increased by cuttings; the stronger-growing kinds are allowed to remain exposed for some time prior to being inserted, so as to dry up the milky matter which they contain. The small-leaved climbing kinds are being propagated from shoots cut up into pieces about six or eight inches long; they are inserted in peat and sand under hand-lights or frames in pits.

MARKET GARDENS.

THE principal work in these now consists in stirring the surface of the soil about growing crops, and in gathering fruit. The principal crops at present ready for market are Cauliflowers, Cabbages, Peas, Broad and French Beans, Potatoes, Onions, Carrots, Vegetable Marrows, Cucumbers, Globe Artichokes, &c. Cucumbers are producing good crops now, and are assisted by applications of manure water. In many cases guano-water is given them in preference to any other, as it is not only highly manurial, but is also believed to be a preventive of red spider. As much as two shillings a dozen is often paid for toads to place in Cucumber frames, in order to keep down wood-lice. Vegetable Marrows are producing abundantly; intervening crops are removed, and the ground mulched. Custard Marrows, which are slower growers than the common sorts, are now also bearing freely. Tomatoes are now receiving close attention in the way of watering, for the retention of which drills are drawn to each side of the plants; they are also mulched with short dung. This crop is being deprived of all suckers and lateral shoots, preserving only the main stem, or at most only such wood as is bearing good clusters of flowers or fruit. They are gone over every few days, thinned, and tied, the latter operation being performed so as to place them on the sunny side of the stakes. French Beans have begun to bear a fair crop. They are commonly grown in single lines from two and a half to three feet apart; between every alternate line is a row of Lettuces. The last sowing has just come up, and the ground about them is being loosened. Among Onions there is as yet little appearance of canker. Indeed, root crops in general look well. Cauliflower ground that has become vacant is new hoed, and afterwards loosened with a fork, but not turned over; by simply loosening the soil a little, what is under the surface is not so apt to become dry. The ground, after being loosened, is planted with Coleworts, about fourteen or fifteen inches apart each way. Good-sized plants are used for this purpose, as they do not yield so soon to the influence of drought. The first planted-out Celery is growing apace, and being in drills about six feet asunder, the sides of the ridges are broken with the hoe, so that a little of the soil may fall round the crowns. On the ridges, or rather curved spaces elevated to about six or eight inches in the middle, are planted Lettuces or Coleworts for winter use. The Celery receives a good deluge of water now and then, and if convenient a little manure water is likewise given to it. To Snow's Winter White Broccoli a little earth is being drawn; this is the kind that furnishes the early winter supply. Brussels Sprouts that were planted between lines of Potatoes, are now growing rapidly, and even where the Potatoes have not been lifted, the haulm has sufficiently drooped to be no obstacle to their growth. Ground that has been occupied by the second and third crops of Lettuces, is again planted with a line of Savoys, and one of Lettuces alternately, the rows being about fourteen or fifteen inches apart. Gherkins are progressing favourably. Superfluous young wood on fruit trees on walls is being removed. Useless and unproductive old fruit bushes are nrosted and burned as soon as the fruit they have borne has been cleared off. Frames, hand-lights, &c., for next season's work are being painted, and otherwise repaired.

PROMENADE AT THE HORTICULTURAL GARDENS.

GHOSTLINESS, says the *Morning Advertiser*, was the prevailing characteristic of the entertainment at the Horticultural Gardens on Friday evening. Seldom has anything been witnessed more original or more weird. Invitations had been issued for a "promenade," and when about nine o'clock we presented ourselves the promenade was in full swing, if the term may be used as applying to that in which there was not the slightest movement or animation. At that hour the gardens were as "gardens in a dream," full of shadows and dim, unreal forms, the whole revealed by the light of a crescent moon, and of a western sky in which long streaks of clouds were changing from purple to black, intersected by a fringe of poplars, as in some one of the gloomiest of Pre-Raphaelite pictures. Here and there, dotted over the grounds, were spectral forms—lovers chiefly, it is devotedly to be hoped—some in morning, some in evening costume, all silent, lugubrious, and reflective. It was a scene and a time for profoundest melancholy—a time for the writing of odes to the moon and stanzas to *Chloe*. Unfortunately, people had assembled with a view to its being a time for enjoyment. Of that we, for ourselves, failed to discover the faintest traces. There was no attempt at illumination. Even the conservatory was like a tomb, wherein one's footsteps echoed as the footsteps of a ghoul. Only one faintly-glimmering spot relieved the pervading gloom. In a dim corner, under a faint cluster of lights, the band of the Horse Guards Blue, huddling together in a faint attempt to decipher their notes, worried through the overture to "Semiramide"—a charming production, but not altogether of the newest or most exhilarating, and scarcely repaying us, as one of an assembled hundred or so, for our wasted evening.

It was understood that this "promenade" was an experiment. Let us rejoice, then, in the reflection that, as an experiment, its failure was utter and complete. It was not attended with even a gleam of redeeming success. Except to those "full fathoms five," and a trifle lower, in love, to whom it offered an opportunity for unlimited "spooning," it was dreary and depressing to the last degree. Only one thing was wanting to complete our misery. It should have taken place on the preceding evening, when the thunderstorm was raging, so that the guests might have huddled together in the dark conservatory, gazing terror-stricken into each other's faces as they were revealed by the lurid flashes of lightning. That would have been a trifle more depressing; or perhaps not, for there would have been the danger and consequent excitement, and these emotions would have saved us from the utter depression and inanity of the actual experimental promenade.

BOILER TRIALS AT BIRMINGHAM.

AWARDS OF THE JUDGES.

THESE trials did not terminate until Saturday week, and it is consequently only within the last few days that the judges—Mr. H. T. Hassall, Mr. Walter May, and Mr. Edward Bennett—have given their decisions, delay having been occasioned by the tedious nature of the investigations they were called upon to make. The *modus operandi* adopted by them may be thus stated:—One thousand feet of four-inch piping were ranged in four sections, at an elevation of several feet from the ground, and connected at one end by transverse piping, to which branches were attached. Parallel with this transverse piping were the various boilers, each of which in its turn was connected by a branch with the transverse piping; but in those cases where the capacity of a boiler was set down in the certificate of entry as being only five hundred feet, one half the entire quantity of piping was shut off by means of a valve. Access to the heated water was gained by the insertion, at the outer end of each range of piping, of vertical wrought-iron tubes, down which highly sensitive "standard" thermometers, supplied by Messrs. Joseph Davis & Co., Polytechnic Institution, Regent Street, were passed. The following are the awards:—The gold medal to Messrs. Hartley & Sugden, of the Atlas Works, Halifax, for their welded wrought-iron chambered saddle boiler, with extended water way. A silver medal to Mr. Benjamin Harlow, Macclesfield, Cheshire, for the best tubular boiler and connections in competition. A silver medal to Mr. Benjamin Harlow, for his improvement in joining hot-water pipes. A silver medal to Messrs. Jones & Rowe, Worcester, for "The Witley Court Boiler," as the best on exhibition without trial. A bronze medal to Mr. Frederick John Mee, Liverpool, for combination of hollow wrought-iron bars, dead plate, and back, for attachment to existing saddle boilers. A bronze medal to Mr. S. Deard, Harlow, Essex, for his small "Amateur's Heating Apparatus." In the communication setting forth these decisions, the judges observe that the trials of the boilers were conducted under great

disadvantages as regards weather—a circumstance which has rendered it very difficult to arrive at satisfactory conclusions; but as some of the boilers were tried more than once, all have been dealt justly by. They consider that in any future trials it will be necessary to house the pipes in some manner to obviate the difficulties caused by variations of temperature and wet weather. They also recommend that the conditions to be complied with by exhibitors should be more precisely and fully laid down.

SOCIETIES, EXHIBITIONS, &c.

CRYSTAL PALACE ROSE SHOW.

(JULY 13TH.)

This was a good show, and, as usual, very attractive. Beside Roses there were Mr. Peacock's group of Succulents; a miscellaneous collection of stove and greenhouse plants, from Mr. J. H. Ley of Croydon; a few stands of Carnations, Picotees, Verbenas, and double Pelargonium blooms, and some table-decorations. Roses in the nurserymen's collections were excellent, and those from amateurs were also good. The principal exhibitors were Messrs. Paul & Son, Mr. C. Turner, Messrs. Veitch, Mr. B. R. Cant, and Mr. Keynes. Amongst the dark-red roses, the best were Louis Van Houtte, Camille de Rohan, Alfred Colomb, Duke of Wellington, Pierre Notting, Charles Lefebvre, Triomphe de Paris, and some others. To S. Reynolds Hole, a most beautiful hybrid perpetual, exhibited by Messrs. Paul & Son, a first-class certificate was awarded. Amongst blush or pink-coloured ones, the following held conspicuous places, viz., Louise Peyronny, Paul Verdier, Comtesse de Chabillant, Mademoiselle Eugene Verdier, Baroness de Rothschild, &c. For prizes offered for collections of yellow roses, Céline Forestier, Gloire de Dijon, Triomphe de Rennes, Maréchal Niel, Madame Falcot, La Boule d'Or, Isabella Gray, Madame Margottin, and others competed. In the class of twelve trusses of any single variety, the first prize was won by Messrs. Paul & Son with a stand of splendid blooms of Alfred Colomb; the second by Messrs Veitch & Son, with Baroness Rothschild; the same rose from other contributors also received two third prizes. Maréchal Niel, from Mr. Turner, likewise came in for a third prize; and a fourth was awarded to a stand of Mademoiselle Marie Rady, from Mr. Coppin, of Croydon.

The table decorations were highly satisfactory. Branched epergnes have, we are glad to see, almost disappeared. The flowers used, we observed, were mostly hardy; but in one of the epergnes, mingled with wild flowers and grasses, were a few sprays of white Orchid blooms, which added a charming richness to the design. Young Palms seem to be a leading feature for centre-pieces, and, where the stems are long and naked, a slender piece of *Lygodium scandens*, hung carelessly around them, adds to their grace and beauty.

Mr. Peacock's Succulents comprised several very curious *Opuntias*, such as *O. robusta*, a large, broad kind, surmounted by two smaller growths, giving the plant the appearance of a flat, shallow plate standing on its side, with two smaller ones attached to its top; *Cereus peruvianus* monstrosus, a very curious plant; also many very remarkable-looking specimens of *Gasterias*, *Mammillarias*, *Agaves*, *Echinocacti*, *Senperiviums*, &c.; the singular *Echinocactus Pottsi*, one of the most odd of all grafted cacti; and *E. bicolor*, a small plant supported on a slender stem, and crowned with a beautiful flower. To these have subsequently been added no fewer than eight van loads of Succulents, all from Mr. Peacock's collection, and which have been on exhibition at the Palace during the past week.

ROYAL HORTICULTURAL SOCIETY.

(JULY 17TH.)

PROMINENT among subjects exhibited on this occasion were half-a-dozen small tubs of Clematis from Messrs. Jackman & Son, of Woking. They consisted of *rubella*, Mrs. James Bateman, Thomas Moore, *rubra violacea*, *Alexandra*, and one of *caerulea odorata*, all in beautiful condition; and in addition to the specimens in tubs, the same exhibitor also staged some stands of cut blooms, magnificent examples of this lovely class of hardy decorative plants. Of Liliums in pots only two groups were furnished, one from G. F. Wilson, Esq., Weybridge Heath, and one from Mr. Bull, of Chelsea. Mr. Wilson furnished examples of the true *L. tigrinum*, one of which was crowned by no fewer than twenty-eight flower-buds. There was also a very fine specimen of *L. longiflorum* Wilsonii, strong in growth, and producing pure white flowers, much larger than we generally see; also another Lily named *L. japonicum* Takesima, with flowers not unlike longiflorum, except that they were scarcely so large, but apparently produced in greater profusion. Amongst varieties in this section may also be mentioned *L. Leichtlini* majus, a tall-growing sulphur-yellow coloured kind, distinctly marked with small brown spots; also the slender-growing, deep crimson coloured dwarf *L. concolor* var. *sinicum*. Messrs. Barr & Sugden exhibited several cut blooms of this interesting family. A few bulbous plants, in the form of Gladioli and Tuberoses, were exhibited by Mr. Standish, of Ascot. A very interesting plant of the giant Hyacinth, *H. princeps*, was sent by Messrs. Rollissou & Son. Phloxes were well shown in pots by Messrs. Downie, Laird, & Laing, and likewise by Mr.

T. S. Ware; amongst the best were Queen of Whites, a pure white; Dr. Masters, a deep crimson; John Laing, a deep crimson shaded with violet; Venus, a light coloured one, with a deeply-marked crimson eye; and others. Three fine specimen Yuccas in flower were furnished by Mr. T. S. Ware, who also contributed some very fine Pentstemons, and a small miscellaneous collection, comprising a new and pretty *Artemisia*, a pretty white, deeply-lacerated *Cineraria*, called *acanthifolia* var. *laciniata*, and a lovely clove carnation, called Chief Justice.

Of hardy perennials, a good collection was supplied by Mr. Parker, who also contributed a group of tender plants, amongst which was *Gloriosa superba*, many *Caladiums*, and some *Marantas*. Mr. Turner had some excellent Carnations and Picotees, also Roses, and some good Pelargoniums, both single and double. Perhaps the most interesting feature at this meeting was the collection of Orchids from Mr. Denning, of Grimston Park, every plant amongst which was of the greatest possible interest. In this group was a plant of *Masdevallia Harryana* with five expanded flowers, several well-flowered *Stanhoopes*, and several fine *Aërides*, *Saccolabiums*, and grand plants of *Anguloa Clowesii* and *Ruckeri*; also a few plants of *Epidendrum vitellinum* majus, one of which, producing large branched flower spikes, was perhaps the finest specimen in flower ever exhibited in England. There was also a good group of Balsams, from Messrs. Lee, of Hammersmith; and a basket of *Bouvardia Vreelandii*, a good white faintly shaded with pink, from Mr. Standish.

Fruit and vegetables were sparingly exhibited; they consisted of a few dishes of Nectarines and Peaches, a few Melons, and a good Providence Pine-Apple. A few very large onions were exhibited by Mr. G. Mills, Wycombe Abbey; nine of the Giant White Tripoli weighed fourteen pounds, and another nine of Early White Naples weighed ten and three-quarter pounds. Among Cucumbers the winning ones were Blue Gown and Fulmer Hero.

First-class certificates were awarded to *Lilium japonicum* Takesima, to *L. tigrinum* splendens, to *L. Leichtlini* majus, all from G. F. Wilson, Esq., Weybridge Heath. Similar awards were also conferred upon Picotee Princess of Wales, Juliana, Edith Dombrain, Norfolk Beauty, Ethel, and B. C. Bryant; also to Carnations Superb, Isaac Wilkinson, and Mrs. Frederick Burnaby, from Mr. C. Turner, of Slough. First-class certificates were likewise awarded to Pelargonium Mrs. Quilter, from Mr. C. Turner; and to Pelargonium Pink Pearl, from Mr. J. King, Allnanry Park, Binglefield.

Cultural commendations were awarded to a collection of Orchids from Mr. W. Denning, Grimston Park; and also to *Masdevallia Harryana*, and *Epidendrum vitellinum* majus, from the same exhibitor. Like awards were given to a stand of cut blooms of Clematises from Mr. Jackman, and to a group of Balsams from Messrs. J. & S. Lee, of Hammersmith; to a Providence Pine from Mr. W. Miller, Worksp Manor, Notts; and to a dish of Violet Hatve Nectarines from Mr. Tillery, of Welbeck.

COVENT GARDEN MARKET.—July 19th.

Flowers, both in pots and as cut blooms, are plentiful. Those in pots consist mostly of Fuchsias, Balsams, and Japan Lilies; also some nice plants of Heliotropes, dwarf Cockscombs, Calceolarias, and great quantities of *Rhodanthe Manglesii*, which is found of great use in bouquet-making. Carnations, mostly self-coloured, may also now be obtained, likewise Pelargoniums, both single and double. Begonias, Marantas, Coleuses, India-rubber trees, little Palms, Screw Pines, and Ferns, may also be seen, together with hanging baskets, both for windows and conservatories. These are filled with Achimenes, turned out of small pots, *Isolepis gracilis*, small Ferns, variegated Panicum, *Petunias*, Ivy-leaved Geraniums, *Torenia asiatica*, &c. For a centre piece, a *Draecena*, an erect growing Fern, a *Gloxinia*, or similar plants are used.

 "This is an art

Which does mend nature: change it rather: but
 THE ART ITSELF IS NATURE."—*Shakespeare.*

ENGLISH GARDENERS IN AMERICA.

BY PETER HENDERSON, JERSEY CITY.

You have alluded at p. 48 to the great mistake made by many English gardeners in coming to the United States at seasons of the year when it is next to impossible to get employment. It must be remembered that the climate of the United States is widely different from that of England, and that its horticulture is yet crude, compared with that of Britain; both these reasons have much to do with those who should emigrate and when they should do so. The regular hiring season for gardeners is in March, and the best time for the emigrant to arrive in New York is during February or March, so that he may have the best chance to select. A great many engagements are made in April and even May, but these are either situations for under-gardeners or for second-rate places.

But for men to arrive during the months of June, July, or August, the chances are more than equal that they may be months without being able to get a stroke to do. The nursery system and even our florists' establishments are carried on entirely different from those of England; so that a gardener cannot so readily drop into them temporarily, as with you, for few skilled men are employed unless regular hands, the bulk of the *employés* being Irish or German labourers. When the Southern States were in their prosperity, engagements were made in the autumn, but since the war, gardening is as yet little thought of in that devastated portion of America; hence, then, although the autumn is not quite so bad a season to come as during the summer or mid-winter months (December and January), yet the safest time is, as I have before said, February or March. Now about the men who should emigrate. I would premise that any gardener having a family should never leave England for America, unless he can make an engagement with a gentleman of whom he knows something, or who can be vouched for by some prominent nurseryman here. Scores of poor fellows are every year deluded in this way, leaving comfortable homes to be set down in some wilderness of a place, and when they have laid it out and beautified it, it is suddenly found that their services are no longer required. But for young men—from twenty to thirty—I think the chances are better than in England. A single man can sooner accumulate money; and business, such as that of seedsman, florist, or market gardener, can be begun with less capital in America than in England; not that money will go as far, for it hardly goes half as far, but there is less monopoly; and, in our quickly-rising towns and cities, business can be begun on a scale so low that you have little conception of in England. I say, then, any young man having an ambition to forward himself in that way has, I think, far better chances to do so in America than in Britain; but if his ambition rises no higher than to be simply a private gardener, there is not much to gain by the change.

Wages are as variable as are the gradations of gardening. A few of the first-class private situations around the larger cities are worth £200 per annum, house, &c.; but these are very few indeed; the majority will hardly average the half of that, and a large number probably not more than one fourth; this even may seem much higher than your rates, but remember that to a man with a family the expenses of living are so much more, that a sovereign in America is not worth more than ten shillings are in England to purchase the necessities of life at the present time; for example, I pay my common labourers nine dollars per week; if single men, five of these must be paid for board; if married, their house takes two from their nine dollars each week.

Single men as gardeners are paid from £50 to £100 per year and board, and, if they are ordinarily saving, may soon accumulate enough to begin business with. The greater number of

the leading nurserymen, seedsmen, and florists of the United States to day are "old country" men, who came out as private gardeners twenty, thirty, or forty years ago, very few of them having £5 in their pockets when they landed. There are few who began by their own savings who have not succeeded, in twenty years or less, in obtaining a comfortable independency, a thing they would not probably have ever obtained in the mother country.

WINDOW PLANTS.

BY J. C. NIVEN, BOTANIC GARDENS, HULL.

THE object of the following instructions is to point out the various operations necessary in the ordinary management of window plants, and the most ready mode in which these operations may be performed, as well as to give the names of such plants as are best adapted for window growth.

SOIL.

There is perhaps no greater difficulty than the occupant of a densely populated town has to contend with than that of getting good soil, or "mould," as it is more popularly called, and I need not say that the sweet and genial character of the soil is a most important element towards success. Only contemplate the sour black material so often used, possibly the result of a small mining operation underneath the cobble stones of a back yard, where it has lain for years deluged with impure water and unsweetened by the corrective influence of the atmosphere; a worse material for laying the foundation of success could not be found. Or possibly a handkerchiefful of road-scraps has been secured for the purpose, which, when used alone, possess a somewhat close affinity to cement, and when first applied to the plant have a tendency to burn the young roots, so that it is more than probable that by the time its fiery nature becomes exhausted the vitality of the plant is also extinguished. Where and how then is this desideratum (a good compost) to be obtained? My answer is, that if any one thing more than another in connection with window gardening belongs to such societies as that at Hull (see p. 55), it is to devote a small portion of their funds to the preparation of such compost, distributing the same at depôts where it can readily be obtained by those who possess plants. This would be a boon as highly appreciated as the distribution of plants in the autumn, because such plants are new acquaintances; whereas these that are pining for lack of proper soil have each their history, aye, histories that not unfrequently reflect some of the brightest beams of the best part of human nature.

POTS AND POTTING.

Garden pots are not expensive, and as they are sold everywhere, I assume that no one who cherishes a plant will begrudge the outlay of a few pence for that purpose; but failing the means, let them fall back on their own ingenuity as to what they will use as a substitute. There is a wide field for them, nor will I attempt to limit it by offering any suggestion beyond this, that whatever the substitute may be, remember every flower-pot is provided with an opening at the bottom for the important purpose of drainage. Further it is important to remember that unglazed ware is better than glazed ware. Assuming, then, that soil has been obtained, and that pots or some substitute has been found, when, it will be asked, are we to re-pot? A very proper inquiry. As a rule don't re-pot plants when they are showing their flower-buds, else possibly they will all fall off, and don't re-pot them in the winter, when nature is at rest. As a general rule the spring-time is best, when Nature's energies may be said to be roused into activity, and when she is best prepared to repair all damages which occur in the operation. In the spring-time—say in the month of April—if the pot in which a plant is growing is small in proportion to the size of the plant, and it evidently requires a larger pot, carefully turn the plant upside down, and tap the pot edge gently on the table, and the ball of earth and roots will come out on the palm of your hand, a perfect representative in shape of the pot it was grown in. It may appear to be nearly all roots, but as the greater part of these will be dead, although here and there will be young active roots just forming, use care. Remove the pebbles at the bottom, and in doing so make a note of what you see, namely, that these open fragments will be full of roots—old roots it is true, and possibly dead by this time—but they have had their use, and learn therefrom that this open material has an important value; and further, that roots, however much they dislike the light, and consequently always grow earthward, like a little air, and the moist air that fills up the space between this material is just what they revel in. After having carefully dislodged the open material from the roots, and loosened the earth by working gently with the fingers at the lower part of the ball, the plant will be ready for its new quarters. I presume, of course, that before you have proceeded

thus far you have a pot somewhat larger ready for its reception; and, if not a new one, it should be well washed, quite as much for the benefit of the plant as for appearance sake. Don't forget the lesson you learned about drainage: put some hard open material in the bottom, lay over it a bit of moss, or, failing this, a few of the dead or decaying leaves of the plant, these will prevent the soil filling up the crevices, and thus destroying the value of this material. Next place the ball of roots in the centre of the new pot, having previously put sufficient soil in the bottom to raise the surface of the old ball to within a quarter of an inch of the top of the pot, then fill in the soil well round, shake it down, and when full press it firmly with the thumbs, turning the pot round with the fingers during the operation. Don't be frightened that you will hurt the roots by pressure, but do it vigorously, for if the soil be left loose the water will escape as through a sieve. When this operation is completed, the surface of the soil will be level, rather less than half an inch below the top of the pot, thus leaving room for a water supply. Don't pile up the soil round the neck of plant—a fault too often committed—such an arrangement naturally sends the water down the sides of the pot, when perhaps the interior of the mass of soil is thoroughly dry. Though I have said that spring is generally the best time for potting plants, I do not say it is always so. Take, for instance, a Geranium, that flowers early in summer. When its flowering season is over it ought to be cut down, say to half its height, or even less. It ought then to be set out of doors in a shady place until it begins to form nice buds and small green leaves along its old branches; this it will do within a few weeks. After exhausted nature has begun thus to show her returning energies, the process of repotting should be attended to; but in this case it is best to shake all the soil away from the roots, trimming the long, straggling ones with a sharp knife, repotting in a smaller pot than that in which the plant previously grew. This small pot will get well filled with roots before winter, and in spring the plant should be transferred to a larger pot in which to bloom, the same process being repeated each succeeding autumn and spring. After potting, unless the fresh soil be in a wet condition—which it should not be—place your pots out of doors on a level place, and give them a good watering, so as to fairly penetrate the mass.

TOP DRESSING.

Supposing the accommodation for a plant in a window is limited as to size of pot, and you cannot arrange for a larger one, then, in lieu of repotting as before described, you may fall back on the expedient of top dressing. In doing this a moderately sharp piece of wood should be used—say a piece of old lath (don't use a knife), and having carefully loosened the surface soil for an inch or more, avoiding any injury to the roots, remove it all and replace with fresh soil. As this operation will be performed only on those plants that have been grown for several years in the same pot, and which will necessarily have impoverished the original soil, it will be advisable to add some stimulant. Possibly you will ask what stimulant you are to use. I will mention two or three which are most easily attainable. One may be picked up in the street or on any roadway frequented by horses, if you get an early start of the street-sweeper. This, mixed with the compost which the Window Garden Society ought to supply, will be a useful stimulant. Another, and one more lasting in character, may be obtained by getting a bone or two, drying them well before the fire, over it, or in it—it matters not which—and with a hammer, or even a flat iron, breaking the bone up into small pieces, as small as you can make them. Use a dessert or tablespoonful of these, according to the size of the pot, to mix with your soil, and you have a storehouse of food that will last the plant for a year or two. A little charcoal broken small is also a good thing, not that it contains much nourishment in itself, but, like a sponge, it absorbs any moisture near it. The charcoal also sucks and stores up all the bad gases in the atmosphere, and gives them out to the plant as the roots require them.

WATERING.

Next in importance to the soil comes the process of watering. How often the death of a plant is to be attributed to injudicious watering. I believe the idea is almost irresistible with many people, that if a plant looks sickly, water is the great curative agent, and that more water can alone restore it. They drown the vital principle in the plant with mistaken kindness. As soon as ever you see the leaf inclined to turn yellow and sickly, be careful with the water; very probably the withholding it for a few days will act as a restorative. The first principle of watering is, never water unless the ball of the plant is dry, and when you water, do it thoroughly, not in frequent dribbles, but give the plant a good drink when it is really thirsty. But you may possibly say, Yes, it's all very well for you to say "when it's dry," but how am I to know when it is dry? By a very simple process. Now, don't try to push your finger down the side of the pot, for you will do more harm than good if you do. Just, for example, tap with your knuckle the pots at this moment on your

window-sill, and if you have an ear for any more refined music than Scotch bagpipes you will detect a difference in the sound produced. One pot will ring with a bit of bell-like music, that's dry; another, knock as you like, returns nothing but a dead leaden sound, that's wet. Having thus told you when and how to water, it only remains to say that in all cases use rain water if you can possibly get it, and in cold weather, take care that the water is about the same temperature as that of the room in which the plants are growing before you use it. Saucers below the pots are useful, but never allow the water to stand in them, but shortly after you have watered your plants empty all that has run into the saucers, so that air may circulate through the drainage material, and act on the soil from below as well as from above. This circulation of air from below is entirely checked by water standing in the saucers. You will remember that I told you after repotting your plant to give it a good soaking, but for some days, possibly weeks afterwards, it may not require any more. During this time evaporation will only take place from the surface of the soil; and the roots, having been damaged, will have to repair the damage done to them, a somewhat slow process, before they can absorb water freely; and therefore, these repairs are more rapidly and efficiently accomplished where the soil is in a moderately dry state.

FROST.

As a matter of course, plants grown in a window are liable to get frozen. To guard against this possibility, it will be advisable to remove the plants from the window-sill during the night, in very severe weather at least. As soon as you see those beautiful vagaries of crystal put in an appearance round the edges of your window-pane, be sure a dangerous enemy is near at hand. If there has been no fire in the room during the day, remove the plants to the further side of the room, and don't replace them till you are assured that the danger is past. Should the plants get frozen by any mischance, what is to be done? Place them in a dark part of the room and sprinkle them with water—cold water, mind; hot water would be death to them. Let the process of thawing be gradual, Nature is never in a hurry.

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM JULY 18TH TO JULY 24TH, INCLUSIVE.)

BY OUR OWN REPORTERS.

Acanthus latifolius	Chamaepeuce diacantha	Hydrangea nivea	Satureja montana
spinulosus	Chelone	Hyssopus officinalis	Saxifraga Chamissoi
Achillea grandiflora	Chrysocoma Conaurea	Indigofera Dosua	Scabiosa Fischei
Ageratum bicoloratum	Chrysanthemum tricolor	Kitabelia vitifolia	suavcolens
Parmacia serrata pl. tanacetifolia	Cirsium ciliatum	Lilium chalcedonicum	Scutellaria scordifolia
Allium striatum	Clematis hybrida	Humboldtianum	Sedum Middeudorfianum
Atheca Heldreichii	revoluta	tigrinum	Sempervivum heterotrichum
Auomatheca curvata	Viticella Colutea	venustum	Seseli gummiiferum
Ambrinium Orontium	Corethrogyne spathulata	Lupinus pilosus	Sileue chlorifolia
Aralia edulis	Cypella Herbertii	Madaria corymbosa	Schafta
Asclepias speciosa	Diathus ramosus	Melissa officinalis	Spartium aphyllum
taberosa	Dierville caudensis	Monarda	Stalice bellidifolia
Aster Tradescanti	Ononis fruticosa	Russelliaua	cordifolia
Astilbe rivularis	Orgaanum Marjorana	Taus	Gmelini
Athanasia annua	Falkia repens	palchellum vulgare	minuta
Bonaveria Coronilla	Fuchsia gracilis	Papaver Buseri	oleifolia
Bravea geminiflora	Genista cotneusis	Pavia multiflorum	Polium Thymus scabral (?)
Calcocolaria pinnata	Geniana Pneumonanthe septemfida	parvifolia	Vandium speciosum
Campanula eximia	Gypsophila acuta	Petrocallis pyrenaica	Veronica crispa
isophylla Rainerii	Helianthus latiflorus	Pimpinella magna	Zephyranthes mesoleuca
raunculiiflora soldanellaeflora	Helianthus rigidus	Polygonum japonicum	Zietenia lavandulaefolia
Carlina acanthifolia	Helipterum Sandfordii	Psoralea acutis	Zygadenus chloranthus
Centaurea gymnocarpa	Hibiscus syriacus	macrostachya	glaberrimus
		Salvia chionantha	

Plants in this list are almost without exception such as have come into bloom during the past week.

A LAD who had lately gone to service, having had salad served up for dinner every day for a week, ran away; and when asked why he had left his place, replied "they made me yeast grass in the summer, and I were afraid they'd make me yeast hay in the winter; and I could not stand that, so I wur off."

THE FLOWER GARDEN.

THE ALPINE GARDEN.

(Continued from p. 8.)

CASCADES, ROCKY BRIDGES, ROCKY MARGINS, ISLETS.

As water is often introduced in connection with rockwork, and high cascades may be frequently attempted, and as the supply often flows from a woody knoll, it is well to take

Waterfall fringed with Yuccas, Dwarf Pines, climbing and trailing plants.

advantage of this position for the arrangement of Yuccas, large grasses, herbaceous plants of noble port, and the like, that cannot well be arranged among the dwarf inhabitants of the

Young Plants of Clematis falling over the face of artificial rock.

rock-garden proper. Among the many plants suited for this position, the new Clematises raised by Jackman and others are the most magnificent. Planted high up on the rocks in a deep

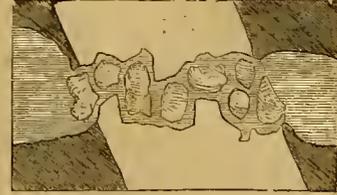

Stepping-stone bridge, with Water Lilies and other aquatic plants.

bed or vein of rich light soil, they will fall over the faces of the sunny crags, robing them as with imperial purple.

Where water occurs near the rock-garden, one or more little bridges are not unfrequently seen; but some such arrangement as that suggested in the accompanying woodcut would be more

satisfactory and tasteful. It is, however, introduced here chiefly for the purpose of showing how well it enables one to enjoy various beautiful aquatic plants, from the fringed and crimson-tipped Bog-bean and graceful Carex pendula at the sides to the golden Villarsia, and Water Lilies sailing among the stones. Arranged thus, a number of interesting plants

Plan of preceding figure.

not usually met with seem to crowd around for acquaintanceship. This mode of garden bridge-making, while infinitely more beautiful than the ordinary one, is less expensive. Care is, however, required to so arrange it that it may satisfy taste, offer free passage to the water, and an easy means of crossing it at all times.

Rockworks made on the margin of artificial water are very often objectionable—rigid, abrupt, unworn, and absurdly unnatural. In no position is an awkwardness more likely to be detected; in none should more care be taken not to offend good

Natural stepping-stone bridge.

taste. Charming effects may be produced on properly made rockwork near water, by planting it with a combination of choice moisture-loving rock-plants—Yuccas, Pampas Grass, and like subjects; but even the grace and beauty of the finest of these will not relieve the hideousness of the masses of brick-rubbish and stone that are frequently placed by the margins of water.

The next figure, showing the fringe of a little island in one

A glimpse at margin of island in Lake Maggiore.

of the lakes of Northern Italy, may serve to show how irregularly and prettily the little waves carve the rocky shore. Frequently in such places diminutive islands from a few feet

Islands in Lake (Westmoreland).

to a few yards across are seen, and, when tufted with Globe-flowers, Ivy, Brambles, &c., are very charming. A few artificial islets may be introduced with good effect near a rocky margin.

(To be continued.)

STOCKS FOR AUTUMN SOWING.

THE summer-blooming stocks being now in the prime of their beauty, seem to remind one that the time for sowing the Brompton, Queen, and intermediate stocks is at hand. There is always a risk about the two former, as a wet and cold winter or severe frost invariably decimates them, but those plants that stand and flower are very beautiful in the early summer. A large-flowering type of the scarlet Brompton can be seen growing in many a cottage garden in the south and south-west districts of London, and it is not unusual to see spikes from one and a half to two feet in length. The Queen and Brompton stocks are closely allied, and are probably only varieties of the same species; but it is curious to note that the seed of the white Brompton is pale in colour, that of the white Queen quite dark. Old growers of the stock distinguish the foliage of the Queen and Brompton stocks in this manner. They assert that the under portion of the leaf of the Queen stock is rough and woolly; that of the Brompton stock is as smooth on the under part as on the upper. Of the Queen stock there are three colours—purple, scarlet, and white; and of the Brompton stock the same number, with the addition of a selected crimson variety of great beauty, but somewhat difficult to perpetuate. Both of these types (if distinct enough to be regarded so) are really biennials, and the seed should be sown at the end of July in beds, and the plants, I need scarcely remark, should be transplanted to the open ground in the autumn.

The difficulty of wintering the Brompton stocks operates to deter many from attempting their cultivation. Even in the case of an unusually mild winter many will die. A well-drained subsoil and a porous surface soil will suit them best. Shelter from biting frosts and nipping winds is of great service. A second transplantation has been tried with considerable success, the last one made about December. The intermediate stocks are much used for cultivation in pots, to bloom in the spring and early summer, and are very useful for decorative purposes. The seed should be sown in August, and the plants, when large enough, placed in thirty-two pots, three plants in a pot, rich soil being used. They should then be placed out of doors in the shade, kept well watered in dry weather, and finally wintered in a cold frame, and drafted into the conservatory or greenhouse as they come into flower.

There is a very pretty variety of the intermediate stock, somewhat taller in growth than the scarlet one, and forming capital pyramids of white flowers. Some of the dwarf German bouquet stocks imported from Germany by our seedsmen make very good intermediate stocks, being dwarf and compact in growth, and well adapted for pot culture. One, of a bright crimson hue, has a very dwarf and yet vigorous habit, and flowers in great profusion. The East Lothian intermediate stocks, as they are termed, are in reality mainly used for late summer blooming, when they are very effective. They are sown in the usual way about the end of March, planted out at the end of May when some three inches or four inches in height, and bloom finely through August and September, and even later, as they throw out numbers of side shoots that produce spikes of flowers. Thus, by using the autumn-sown intermediate stocks for early blooming, the ordinary large-flowering German ten-week stock for summer flowering, and the later East Lothian intermediate stocks for late summer work, stocks can be had in flower eight or nine months of the year without intermission. Q.

ROSE BUDDING.

WHAT is the proper time for budding with a dormant bud? As late as possible, *i.e.*, before the sap ceases to flow. In general the last two weeks of August, or even the beginning of September, is a better time than the end of July. Should there be a deficiency of sap, it may be stimulated into renewed action by watering. Late budding has the two following advantages: 1. The buds take without sprouting before winter, and consequently suffer less from the frost, and push more vigorously in spring. 2. We are enabled to take buds from those shoots that flower continuously or several times, and these are the only ones that will reproduce shoots of a similar character.

Should buds be taken indiscriminately from all parts of a shoot which flowers continuously? No; and the three following rules will serve as a guide in this matter.

Rule I. Buds taken from the lower part of a shoot produce shoots which are at the same time not vigorous and bear few flowers—facts which at first sight appear irreconcilable; but we will give reasons for the statement. 1. The buds on the lower part of a shoot—a part which is in a condition of imperfect development—are themselves weakly, and cannot produce any but feeble shoots. 2. They bear few flowers. We shall give the reason for this presently; but will first state the second rule.

Rule II. The buds at the top of a shoot produce shoots which are moderately vigorous, but which flower very abundantly. That the vigour of shoots produced from such buds is moderate sufficiently explains why the buds themselves are only moderately vigorous; but that they should bear flowers most abundantly is undoubtedly a verification of the observation made by M. Vibert that buds will produce shoots which have a greater tendency to bear flowers in proportion as the buds from which they spring grew nearer to the flower on the parent stem. Thus the shoots on the lower part of a branch hardly ever flower, and the buds at the base of a shoot produce shoots which are almost always sterile.

Rule III. To understand this, it will be sufficient merely to state it. Buds taken from the middle of a shoot produce shoots which are sound and vigorous, but only moderately free-flowering.

These principles, which were laid down thirty years ago, have just been verified in a very intelligent manner by an excellent gardener—M. Bourdon, of Clairoux. In the rich soil of his grounds, buds taken from the lower part of shoots of the most free-flowering varieties have remained almost sterile, six grafts of *Maréchal Niel* having produced only one flower. The buds taken from this single flower-bearing shoot, close to the flower, produced shoots each of which bore a tolerably large number of flowers—fifteen to twenty.

The very free-flowering varieties, *Madame Damage* and *Auguste Mie*, have afforded subjects for interesting remarks. The buds of these taken from the lower part of the shoots produced rather feeble shoots, each bearing one or two flowers at the most; while buds taken from the upper part of the shoots near the flower produced, according to my experience, shoots which were covered with a rich profusion of blooms.—*Professor Raquet, in "Belgique Horticole."*

FUCHSIA RICARTONI AS A HEDGE PLANT IN IRELAND.

I BEG to corroborate all that your correspondent "Z." says in your paper of the 15th ultimo, in favour of the *Fuchsia Ricartoni*. Here with us it is valued even more for its substantial uses than for its beauty. I live in a stormy climate on the edge of the ocean (which, however, I do not admit to be "melancholy"), and although my kitchen garden is surrounded with a semicircular wall of some eleven feet high, I need interior shelter, and this is altogether provided by hedges of the *Fuchsia Ricartoni*, which are made by branches cut or broken into bits of any size you please, and stuck into the ground close together in a line. This affords very fair shelter the second year, and from that time forward the only difficulty is to keep your hedge within bounds. The beauty of these hedges at this time of year is extraordinary, and they are so self-sheltering, and our climate is so mild in winter, that they hold the leaf for a very great portion of the year. As to size, we quite surpass anything mentioned by your correspondent. I have one tree of *F. Ricartoni*, planted in my flower garden in the autumn of 1854, on which no care has been bestowed. It would have been much larger than it is now if it had not been for some years cut back at one side from a gravel walk. For the last five years I have let it have its own way, and allowed it to overrun gravel walks and ribbon borders, and each year I have had its measure carefully taken, and recorded by witnesses. In 1870 its circumference, measured with a line round the extreme tips of the branches, was 107 feet 7 inches; last year it reached 115 feet; and I will venture to say that this year it will considerably exceed 120 feet. I do not think it is more than 13 feet or 14 feet high. We have many much taller-growing among trees in sheltered situations. In a year or two it will reach the main walk of my garden, which cannot be allowed to be closed; so I propose to arch over the walk with a trellis, over which I expect the *fuchsia* will gradually grow, leaving a passage clear underneath. After that it will meet nothing to check it till some few yards further on it will reach a low cliff, which forms the shore of the harbour, and then I must leave it to settle its "Alabama question" with the ocean aforesaid.—*P. FitzGerald, Knt. of Kerry, Glanham, Valencia.*

CENTAUREA BABYLONICA.

AMONG the Centaureas by far the most distinct and remarkable is the very silvery-leaved *C. babylonica*. It is quite hardy, and when planted in good ground, sends up strong shoots, clad with yellow flowers, to a height of ten or twelve feet. The bloom, which continues from July to September, is not by any means so attractive as the leaves; but the plant is at all

Centaurea babylonica.

times picturesque. In groups, or, still better, isolated, on rough or undulating parts of pleasure-grounds, it has a very fine effect. When the leaves alone are seen, it is worthy of a place among the finest hardy variegated subjects, but when it sends up its strong stems, it is a fit associate for hollyhocks, and the very tallest herbaceous plants.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Pelargoniums in the Flower Garden.—It is not well enough known to amateurs that many bare spots in their beds may be soon furnished by inserting in them cuttings of variegated or green-leaved Pelargoniums. If closely set they are effective at once. Some kinds will root and flower well in a fortnight. The leaves at first look prettier than those of tall plants, as they sit so close to the ground and are so fresh-looking.—W. F.

Autumn-Sown Sweet Peas.—In August last I sowed some sweet peas as an experiment, that I might by chance obtain a late autumn bloom, in which I was deceived; but the peas growing well, my gardener banked them up in the winter with ashes. I have now hedges of sweet peas at least eight feet high, with haulm as strong as that of the everlasting pea, which have been in full bloom since May 30th. The flowers are magnificent, and I shall certainly try the autumn sowing again, should I be spared to do so. I send this as a hint to amateur gardeners.—R. M. L., *Hampton Wick, Kingston-on-Thames*.—[We are not surprised to hear your autumn-sown peas are so much finer than those sown in spring. There is often a very remarkable difference between annual plants sown in autumn and in spring, and there can be no doubt that all such plants as bear our winters should be sown in autumn.]

Bulb Culture in Holland.—The far-famed Dutch bulbs are chiefly cultivated near Haarlem and Lisse, and owe their superiority as much to the suitable texture and position of the soil—a calcareous sand resting on peat—as to the lavish use of manure. An area of 125 acres, devoted to hyacinth-growing near Haarlem, is estimated to bring in a revenue of nearly £30,000. In 1859, bulbs were exported to the value of £12,700; and in 1862 the village of Bloemendaal, “the Valley of Flowers,” sent forth no less than £200,000 worth. Where bulb culture is the main object of attention, the routine is frequently as follows:—**First year.**—The soil is broken up and dug to a depth of five or six inches, a heavy dressing of cowdung is applied, and a crop of potatoes taken. In the autumn the bulbs are planted, and the beds remain covered with reeds until the month of May. **Second year.**—About midsummer, the bulbs having been collected, grass is sown on the paths between the beds, and in the autumn tulips, crocuses, and occasionally different kinds of narcissus and ranunculus, are planted on the green sward.

GARDEN DESTROYERS.

THE NEW ENEMY TO THE VINE.

(PHYLLOXERA VASTATRIX.)

UPON reading in THE GARDEN of the 28th June last (p. 700), that “a new blight of a fatal character—the Phylloxera—had made its appearance in Bas Languedoc, and was causing very great alarm amongst the cultivators and proprietors of vineyards, and that in the district of Comtat the vine had already disappeared,” it occurred to me that the following account of the new enemy to the vine, translated from a periodical published at Ghent (*The Flore*, vol. 17), might be acceptable to your readers:—

In some localities of the south of France, the vines are suffering from the ravages of a destructive insect, which has lately been noticed for the first time. M. E. A. Carrière has published in the *Revue Horticole* an extract from an article which M. J. E. Planchon contributed some time ago to the *Comptes Rendus de l'Institut* (1868, p. 588). Here is the passage from the *Revue*:—I will here give a brief *resumé* of all I learnt about the habits of the Phylloxera vastatrix from a series of observations made on the spot, in three short visits to the south of France; also all I noticed with reference to the specimens which I kept in glass bottles during forty consecutive days. Its best known form is that in which no trace of wings can be discovered. When the insect is about to lay its eggs (that is, in its adult female state), it forms a small ovoid mass, having its inferior surface flattened, its dorsal surface convex; being surrounded by a kind of fillet, which is very narrow when it touches the thoracic part of its body, which (formed by five rather indistinct rings) is hardly separated from its abdominal part of seven rings. Six rows of small blunt tubercles form a slight protuberance on the thoracic segments, and are found very faintly marked on the abdominal segments. The head is always concealed by the anterior protuberance of the buckler; the antennæ are almost always inactive. The abdomen, often short and contracted, becomes elongated towards laying time, and there can be easily seen one, two, or sometimes three, eggs in a more or less mature state. The egg sometimes retains its yellow colour for one, two, or three days after it has been laid; more often, however, it changes to a dull grey hue. From five to eight days generally elapse before it is hatched. The duration of this period depends a good deal on the temperature. The quantity of eggs, and the rapidity with which they are produced, are probably determined by a variety of circumstances—the health of the insect, the quantity of nourishment it is able to obtain, the weather, and perhaps other causes. A female which had produced six eggs at eight o'clock a.m. on the 20th August, had fifteen on the 21st at four p.m., that is, she laid nine in thirty-two hours. Other females lay one, two, or three eggs in twenty-four hours. The maximum quantity is thirty in five days. The eggs are generally piled up near the mother, without any apparent order, but she sometimes changes her position so as to scatter them all around her. They have a smooth surface, and adhere lightly to each other by means of a slimy matter which attaches to them.

Hatching takes place through an irregular and often lateral rent in the egg, the empty and crumpled membrane being found among the other eggs in different stages of hatching. During the first period of their active life—two, three, four, or five days, as the case may be—the insects are in an erratic state. They creep about as if they were seeking for a favourable situation. Their movements are more rapid than those of adults. They appear to inspect, as it were, with their antennæ the surface they travel over. The movements of the antennæ are generally alternative, and, if the comparison may be pardoned, are not unlike the two sticks of a blind man, which he uses to explore the ground he is about to tread. After a few days of this errant life, the young insect seems to fix upon a spot to settle in. Most frequently there is a fissure in the bark of a vine, where their suckers can be easily plunged into the cellular tissue, full of saccharine matter. If you make a fresh wound on the root by cutting off a little piece of bark, you may see the “Pucerons” range themselves in rows around the wound, and once fixed, they apply to the root their antennæ, which appear like two divergent horns. At this period of their life, about the thirteenth or fourteenth day after their birth, they are more or less sedentary; but they change their places if a new wound is made on the root, which promises a fresh supply of food. What sense is this which direct these subterraneous “Pucerons” towards the place which is most suitable for them? It cannot be sight, as their eyes are merely coloured spots, and they creep as if they were blind. It cannot be hearing, because they seek no prey but a vegetable tissue. It is probably the sense of smelling; and we may well ask if the nuclei, which appear enshrined in the last articulations of the antennæ are not the organs of this function, the seat of which has been so much disputed? Among these non-adult insects, attached by their suckers to the vine roots, are seen, here and there, some of middle size. Their colour is a deeper orange, the abdomen shorter and more squarely formed. These individuals are more sedentary than the others. I have sometimes imagined they might be wingless (apterous) males of the species; but as nothing has happened to confirm this very problematical hypothesis, and as I have seen undoubted females resembling these examples in colour and form, I incline to the belief that there are no sexual differences among them. A kind of double moult precedes the adult state. The first takes place shortly after hirth, the second after laying time. Some uncertainty, however, hangs over the number of their changes, as the

cast-off skins are often found mixed up with groups of Pucerons of different ages, and it is difficult to distinguish them. On the morbid tuberosities of the fibrous vine-roots, or on the offshoots of the roots, the Pucerons (perhaps better nourished) seem to pass more quickly through the different phases I have described; but excepting that their colour is paler, they present no marked difference.

The winged form of the Phylloxera might easily be taken for a separate species. The rare specimens which I have seen have all come from the Pucerons nourished on the newly-attached vine radicles. In their infant (or it might be called their larva) state they resemble those which I have suggested may be males; but the buckler soon becomes more strongly marked than in these last, and a kind of band seems distinctly to define the separation between this and the abdomen. The sheaths of the wings, triangular-shaped and of a greyish colour, appear on both sides of the buckler. It is easy to predict the advent of a winged insect from this chrysalis. When one of these nymphæ is seen to quit its place, and to crawl over the root or up the side of the bottle where it may have been put, its transformation is near. Soon, instead of a sort of pupa, a beautiful little fly appears, whose two pairs of wings, crossed horizontally, are much larger than its body. It is impossible to doubt the identity of this insect with the Pucerons which formed one of the swarm on the vine-root. The details of the structure of certain organs—the antennæ, claws, varsi, and suckers—establish their identity. The horizontal position of the wings completely distinguishes the Phylloxera from the type *Aphis*, whose wings are always more or less inclined upwards. The two larger wings, obliquely oboval and cuneiform, have a lineal areole on the larger basilar half of their outer edge; and this is enclosed in an interior "nervure," which answers, I suppose, to the radial muscle. One single oblique nervure (or corneous division) is detached from the last, and reaches to the inner edge. Two other lines start from the end of the wing, and, becoming narrower as they proceed, advance towards the oblique nervure, but end before reaching it. These are not, perhaps, nervures, but rather folds, for I have observed them absent. The inferior wings, both narrower and much shorter, have a marginal nervure running from the base to the middle, but it loses itself in a gentle protuberance, which the wing shows in this place; a radial nerve runs parallel to the first, and disappears before it reaches the same spot. The eyes, black and (relatively) very large, are irregularly globular, with marked conical nipples. Their surface is granular, but a pointed depression is observed in the centre of each glandule. A round eye-shaped spot occupies the centre of the forehead.

Among fifteen specimens of the Phylloxera which have come under my notice, not one has presented any sexual difference. Almost all of them laid two or three eggs, and their deaths (which happened soon after) may have been caused by their imprisonment in the bottles. Their eggs resembled those of the wingless Phylloxera, and though they were only two or three in number they completely filled the abdomen of the mother. They were easily seen by placing the insect under the microscope. I do not know how long the eggs remain before they are hatched, or if they always produce the winged form of the insect. It is probable that these winged individuals serve for the transportation of this insect plague to a distance, and that these wings would serve them for a rapid flight—they are too inactive, they move them very little, and in rising from the ground their horizontal position is preserved. My observations, were, however, made under very unfavourable conditions—the insect being in a state of captivity; but I suppose that even in a natural state the wind is the principal agent for the dispersion of the Phylloxera, as it is for many of the insect tribe. In any case, the discovery of this form of Phylloxera provided with wings, and evidently fitted for an aerial life, is sufficient to explain the hitherto embarrassing fact of the rapid spread of the vine-plague. As to the spread of the disease from one vine to another, the wingless Pucerons may suffice for this, as, grouped in great numbers about the lower part of unhealthy vine-stems, they might easily attack the vines nearest them, even if they be healthy. It may be asked, in what manner do these insects manage to travel from one vine-stock to another, and how do they contrive to reach the fibrous roots of the newly-attacked stocks? Do they burrow under the soil, or do they not rather travel along the surface of the earth under cover of the darkness and coolness of night, and then, traversing the fissures in the bark, arrive in this manner at the extremities of the roots? This conjecture is a probable one, and the following experiment supports it:—

In a case one yard long I placed some garden soil from Montpellier, a place entirely free from Phylloxera. In this earth I carefully laid some pieces of vine cane infested with wingless Pucerons. I placed a hand-glass over each cane, and slightly raised the glass on one side, in order to allow the insect to creep out. At three centimetres distance from the pieces of cane I put some fragments of root from a healthy vine, in which I had made fresh wounds. In twelve hours the following results were obtained: three Pucerons had found their way from one of the vine canes to the nearest piece of vine-root. Some days after, twenty young Pucerons occupied the same fragment. A few insects were to be found in the other fragments. One piece of root had attracted none, but the vine cane nearest to it had very few insects upon it which were capable of changing their places. A similar experiment has been made by Mr. Frédéric Leydier, at the farm of Laucieux, near Sigondas, a part of the country already infested by the Phylloxera, and by another person near Sorgues. The results of these experiments have not been satisfactory; but this does not prove that under other conditions, or with a greater amount of perseverance, they might not have been successful. It is fortunate that the new enemy to the vine attacks it, in the first instance, at the base of the stem, and not underground at the fibres. As it is, a thorough

dressing of the bottom of the stem with coal-tar will probably prove an insurmountable obstacle to the progress of this destructive insect; but were the case otherwise, it would be very difficult to get down deep enough to reach an enemy so well protected by the depth of the soil.

From all we hear there cannot be a doubt but that this pest has already made its ravages on some of the vines in this country. A short time ago a gentleman in the south of England informed me that his vines would not grow more than two or three inches; he determined to take them up, and examine the roots; he did so, and found them swarming with the Phylloxera. They could be seen with the naked eye, looking like grains of yellow sulphur, in the crevices of the roots, and with a glass of good power they were distinctly visible. The roots were barked by the insects, and the vitality of the vines was destroyed.

It must be borne in mind that from the high state in which the vine is now cultivated, it is much more susceptible of attacks from insect plagues, and requires more watchfulness and skill on the part of the cultivator to guard against them. The best remedy which I can suggest for the disease is, that, immediately the Phylloxera is discovered, whether in a private garden or a nursery, it should be "stamped out."

DELTA.

"THE VERMIN ASPHYXIATOR."

SUCH is the title of a machine of ingenious but simple construction recently invented by Mr. Samuel Bateson, and commending itself at once by its name to the notice of gardeners and others who suffer from the depredations of vermin. It consists of a small iron furnace or crucible, connected by a pipe with a circular chamber in which a fan revolves. The lower part of this chamber is shaped into an aperture or nozzle, to which india-rubber tubing of any required length can be fixed, and the machine is put in action by turning a handle; this sets the fan in motion, and expels through the tubing with great velocity and regularity, and in a condensed volume, the vapour, be it sweet or foul, health-giving or life-destroying, of the compound burning in the crucible. The expulsion of vapour by means of a fan is of course an old and well-known method, already employed in a great variety of processes, and the novelty of the asphyxiator consists, firstly, in several contrivances rendering its action and construction simple and durable and the whole machine handy and portable; and, secondly, in the idea of utilizing for so many purposes from one machine a forcibly-propelled stream of vapour, which may be poisonous or sweet-scented, sulphurous or merely smoky, according as required. In the waste ground behind the west wing of the International Exhibition, Mr. Frank Buckland explained, the other day, the action of the asphyxiator, which he said was valuable as a fumigator for sanitary purposes, and infinitely more handy than the old system of fumigating by means of burning sulphur pots, since it can be used from without, the nozzle of the tube being inserted through a hole in the door or hatchway. Mr. Buckland's first experiment was upon two plants covered with aphides. These were placed in a glass case, to which was fixed the nozzle of the tube leading from the fan chamber of the asphyxiator, the furnace being filled with a specially prepared "insect destroying paper." The glass case was soon clouded with impenetrable fumes, and when, after a few minutes, the reeking plants were removed, it was shown that the aphides were no more, while the plants were no worse for their vapour bath. Other experiments were tried on snakes and weevils, and with equally satisfactory results; indeed it was clear that the asphyxiator would prove most invaluable for the destruction of vermin, and for every purpose of disinfection and fumigation. If it can be made generally effective in the open air, what a blessing it will be to gardeners and hop-growers!

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

The Cabbage Butterfly.—According to Dr. Uhler, of Baltimore, the European cabbage butterfly, the pest of the English cultivator, has at last reached Baltimore in its invasion of the United States. It has been known for some years more to the eastward, and has been slowly but surely creeping along, until it bids fair to involve the whole country in its ravages.

Ants versus Caterpillars.—Ants appear to be the most inveterate and bitter foes of field caterpillars. The farm inspector Sternelborg, of Lippstadt, gives a report of a trial thus made to get rid of caterpillars:—In the year 1871 the garden of the postmaster Ludwig, at Ruthen, was devastated by caterpillars. Cabbage plants of all kinds were threatened with destruction. In this extremity a labourer brought a sackful of large ants from the forest, and strewed them over the cabbages. The caterpillars took to instant flight, and, as fast as their means of locomotion allowed, they hurried over wall and hedge with all possible speed, and by the following day not a single one was left in the garden.

WE have heard of the "flowers of rhetoric,"—its fruits are the Queen's peach.

THE ARBORETUM.

TRANSPLANTING LARGE TREES AT BROOKLYN.

THE moving of the trees in the fine park at Brooklyn (of which we gave a plan in our number for June 22nd), was an important and very successful operation. At the time the lands of the park were taken, there was a large number of fine young trees of natural growth, from twenty to forty feet high, and from five to fifteen inches in diameter of trunk, in situations where, in the construction of the projected improvements, they would have to be removed or destroyed. On the line of some of the former roads and streets within the present park area, and more especially on some improved private grounds outside, there were also many fine young trees of varying sizes, chiefly maples, elms, lindens, oaks, &c., which had been planted from ten to twenty years ago, but which were in positions where it was not desirable for them to remain. For the removal of these a large truck was specially designed by Mr. Culyer, the chief engineer, and constructed for this purpose, and the following season—November 1867 to April 1868—over one hundred trees were moved with it to desirable positions in the park. It was found quite practicable with this

American Transplanting Machine.

truck to carry balls of earth surrounding the roots twelve to fourteen feet across and more than four feet in depth, with a weight, including tree top, estimated in some cases as exceeding fourteen tons. From the accompanying illustration of the truck, the method of carrying the tree can readily be understood. The following season another truck was built, on the same general principles, but of a somewhat smaller size, and more especially designed to carry shrubs or trees branching near the ground. With these two trucks over nine hundred trees of similar size have since been transplanted.

The result has so far been quite satisfactory. Many even of the larger trees have already well recovered, and are now flourishing finely. A considerable number have as yet a stunted, stationary character, while with some a renewal of permanent vigour seems doubtful; but the actual loss, so far, has only been about one in a hundred. The kinds which have been thus moved by the trucks in greatest

numbers are maples, elms, lindens, birches, hornbeams, and dogwoods. Some ashes, oaks, cherries, tulip trees, sweet gums, walnuts, chestnuts, and beeches of similar size have also been successfully moved from locations where there was sufficient clay in the soil to make the ball firm and cohesive; but, except in stiff soil, the risk of moving these is too great to justify extensive operations. No hickories of any large size have been attempted, as, from their peculiarly large and deep tap roots, they are very sensitive to any injury. About twenty spruces and pines, from fifteen to thirty-five feet high, have likewise been moved by the trucks. The method of raising and lowering the tree, and working the truck, is briefly as follows:—A trench is dug around four to seven feet from the stem according to the size of the tree, and as deep as the roots descend, and the soil is taken away from beneath the latter until only a small central prop is left, just sufficient to support the tree. Strong chains and timbers are then placed under the ball; the truck is detached at the place indicated by the clamp fastenings; each part is wheeled into position from opposite sides, enclosing the trunk, and then fastened together again. The chains are attached to the tackles, and, by levers, are easily wound on to the windlass until the ball is high enough to clear the ground in conveying the tree to the place where it is to be planted.

The excavation to receive the tree is made rather deeper and much wider than the ball, and is filled in to the proper level with good soil; the truck is then drawn over the hole, the wheels being supported on strong planks if the hole is wider than the truck, and the tree is lowered easily to the prepared bed. The trench around the ball is then filled up with good soil, any exposed or bruised roots being first cut off smoothly. Unless the soil around the roots be very gravelly or sandy, very little of it drops or is jarred off during the operation.

J. Y. C., Brooklyn Park.

INFLUENCE OF FORESTS ON RAINFALL.

THAT forests do not induce and control storms is no doubt true, but to infer that they have no influence on the rainfall would be little less erroneous than to suppose that the amount of woodland would be a measure of the rain that might be expected. Extensive countries were in former ages highly productive, and hence it is supposed were watered with abundant rains, but are now nearly barren and seldom have rains, and hence it is inferred that denuding the soil and exposing it for centuries to the hot sun and drying winds is the reason there are no rains or storms. This is, no doubt, an error; although the amount or want of forests may have no considerable influence and effect on the rainfall during the warm part of the year, other causes and influences, as shown by meteorology, are mainly instrumental in inducing and controlling storms. Many are rather liable to jump at conclusions, and sometimes go from one extreme to the other. Finding that forests do not entirely control the rainfall, they are liable to go to the other extreme, and say they have no influence at all. It is, nevertheless, a fact that, while other agencies may have a controlling influence in inducing storms, still the presence of considerable woodland may make a material difference in the amount of rain during the growing season of the year. How the forests may thus affect the rainfall I will now try to show.

Water is evaporated by heat and diffused through the air until condensed by cold, when it usually falls in the form of rain. Condensation is first seen in the form of a cloud, very light and high perhaps at first, but lower and heavier as the moisture in the air becomes more condensed. A familiar idea of a cloud may be found in Professor Henry's statement that a "fog has been aptly called a cloud resting on the earth, and a cloud a fog suspended in the atmosphere." A cloud is of the same weight as the stratum of air in which it floats; and as, in all sections except on mountains, clouds are at some height, it follows that they are lighter than the air at the surface of the ground; consequently clouds are as easily moved through the atmosphere as the winds, and hence are extremely sensitive to the slightest attraction or influence. As water has an attraction for water, it is easily seen why clouds and rains are naturally drawn towards large bodies and streams of water, as well as towards cool, moist woodlands. Another cause of more rain in such places is that the cool, moist air over water and woodland favours condensation, when it is fairly started, and thus increases the amount of rain; but a dry, hot surface air has the opposite effect. This last influence is so great in some places as entirely to prevent rain falling at any time of the year. Of this good authorities furnish many examples. Thus it is seen how the clouds and moist winds result in rain, when condensed by the colder mountains, in the one case, and are dispersed and diffused through the atmosphere by the hot, dry air of the desert on

the other. California furnishes another good example. In a large portion of the State the westerly winds blow from the Pacific Ocean nearly all the year, and in summer, when, of course, evaporation is the greatest and the winds contain the most moisture, there is no rain, as the surface of the ground and the surface air are warmer than the winds; in the winter, when the winds naturally contain the least moisture, but the ground and the surface air are cooler than these ocean winds, they get their supply of rain for the year.

The same agencies and influences in nature are always at work in all sections, the cooler and more moist air in and over woodland favouring rain, while the hotter, drier air over wide, open countries, has the reverse effect. Then no slight cause of droughts, or of the greater severity of droughts during hot weather, in such open countries, is the wide and strong sweep of the winds, which often carry off the evaporation and moisture, to be finally condensed in some more favourable section for that purpose, perhaps, over the Atlantic Ocean. With plenty of woodland to break up these winds and thus favour condensation, this carrying off the moisture that is needed in the country may be much less general and severe. Scientific men explain that the amount of rain in a shower or storm may be influenced by the amount of moisture in the air at the place. Thus, in the vicinity of lakes and large rivers, or of large bodies of woodland, where the air is cool and moist, there may be a heavy rain; while over hot, dry plains, where the air is very dry, the same storm may be very light, perhaps, it may not rain at all. This will explain the failure of some storms that afford plenty of rain in most places, while in others there is very little. In the latter places these storms, or more properly appearances, seem to get all ready to rain, and look as though they would rain in a very short time; and yet the clouds hang over the country and finally work off without giving any rain to amount to anything. In such cases, as in the deserts and other places above referred to, no doubt the hot dry air and the dry winds prevail and carry the moisture, so nearly condensed in the clouds, to other regions.

Although these remarks apply to summer storms generally, they are especially true in regard to showers. Showers are peculiarly sensitive to local influences and attractions, and especially to those described above; and as they are the main dependence during summer droughts, every influence that affects their number and the amount of rain at any one place at once becomes important. A slight difference, to the casual observer, in the condition of the air and in the condition and amount of the winds may make all the difference between plentiful showers and none to do any good.—

Cultivator.

LILACS.

It is a matter of regret that we appear to be satisfied with the common varieties of the lilac, and that such excellent kinds as Dr. Lindley and Charles X. are not planted in preference to, or at least to an equal extent with, the commoner kinds. These are limited to three: *Syringa vulgaris*, *S. dnbia* (or *rothomagensis*), and *S. persica*, with a few of their varieties; and it is one or other of these kinds we are sure to see in our gardens or pleasure-grounds. On the Continent, however, there is no such poverty of selection. We take up at random a Continental catalogue, and there we find a very extensive list of good varieties, at such low prices that there is very little excuse for us if our ornamental plantations are not speedily the better of it. This list we reproduce for the benefit of our readers; it will serve to show to what a remarkable degree these fine shrubs vary, and we can assure our readers that many of them are more beautiful than those we grow to such a great extent.

THE POISON OAK.

(RHUS TOXICODENDRON.)

This trails along the ground, rooting at intervals, and should it come in contact with an oak tree, it fastens itself to it and runs up it; yet the oak is not the only tree it so tenaciously adheres to, for to other trees or walls coming within its reach it attaches itself like

ivy. The leaves consist of three leaflets, the stem attains a thickness of from two to four inches, and climbs to a height of forty feet. The poisonous effects of this plant are very great, and to some people more so than to others. To some persons the touch of the leaf is poisonous, causing an irritating eruption of the skin. Simply touching or carrying a bunch of these plants sometimes causes the hands, arms, and even the whole body, to become greatly swollen, the swelling being accompanied by intolerable pain and inflammation, and ending in ulceration. Its poisonous effects are also sometimes felt even by passing to the leeward of a bush on a windy day, or going through the smoke of a fire in which it is burning. These effects are not felt by every one, some people being able to handle this plant with impunity.

TREES IN COVENTRY.

We are glad to record that for some time past a committee has been formed for the planting of the roads near the ancient city of Coventry, and that when we last visited it considerable progress had been made in planting. The committee is composed of some of the most influential gentlemen of the town, and the planting is carried out by Mr. Dawson, the manager of the Coventry cemetery. The planting is paid for by subscription, and not more of it carried out each year than the funds in hand will admit of, so that no debts are incurred. We recommend the excellent example thus set by Coventry to many others of our towns, in which the hideousness of acres of brick is not relieved by a single tree.

SHADE.

WHEN bright sunshine prevails how delicious it is to retire to the cool and welcome shade of leafy, overhanging trees. At such a time the grandest of Deodars, or the finest of Wellingtonias, has not half the charms of the humblest oak or the most uncouth chestnut. To get beneath leafy branches, if but for a few minutes, seems to give immense relief. What inhumanity it is to turn even dumb animals into an enclosure where there are no trees to break the rays of the summer sun. Trees planted here and there, though but ever so few, would in a few years cast on the ground shadows that would be welcome both to man and beast, while the beauty of the landscape would be increased. When planting, do we think enough of the probable wants of posterity? Londoners have much to be thankful for as regards the rich umbrageous foliage that overhangs the great parks of the West End. Our forests, our woods, and groves, planted in times gone by, that they might grow into money's worth, are to us, during the heat of summer, of incalculable value. The noble oak standing just in front of my cottage, was probably planted there some one hundred years or more ago; perchance then the thought of a dwelling being near it was the last thought that entered the minds of the planters. Perhaps the land then was common, and the big tree of to-day was, after all, but a chance seedling from some grand old progenitor that has now passed the way of all that is earthly. In any case, there it is; and now when the sun pours down its rays with intense force, how grateful am I for its shade! how delightfully my little ones sport beneath its branches! how pleasant to carry out a few chairs and a table, and there enjoy in coolness and comfort the evening meal, and the "cup that cheers but not inebriates!" I am grateful for its shade. Our magnificent forest trees are the glory of our land. May our fondness for the denizens of other lands not make us forget the debt of gratitude which we owe to our forefathers for the trees and plantations which they have left us, nor neglect to keep for posterity a supply of those noble trees that are so richly endowed with the power of shade.

A. D.

Trees on the Thames Embankment.—We are glad to say the Plane trees on the Thames Embankment are now looking fresh and vigorous, and evidently beginning to grow well. Near the Houses of Parliament they seem weakest, but all the way thence to Waterloo Bridge many nice healthy young trees may be seen. It was supposed by some that the Planes would not thrive on the Embankment; but this has proved erroneous. We must confess, however, that, with Mr. Noel Humphreys, we share the opinion that in all cases of extensive street and road planting no effort should be spared to introduce as much variety as possible among the trees. There are a good many trees that thrive as well in towns as the Plane, and for many reasons, needless to enumerate here, it is desirable we should see as much tree beauty as possible in our towns.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE SWEET-SCENTED EASTERN THORN (CRATÆGUS ODORATISSIMA).

THIS forms a low spreading, round-headed tree, from ten to fifteen feet high, with numerous branches, more or less curving downwards, and thickly furnished with declining, downy, spineless shoots. It is a native of the Levant; it is quite hardy, grows freely in any garden soil, is never injured by the larvæ of insects, and is the latest of all the thorns in leafing and flowering. It was first introduced in 1810.

The leaves, which have a hoary appearance, are more or less pinnatifid, but they vary very much in shape and size; those on the older parts and fruiting spurs are very deeply cut, with the divisions narrow, sharp pointed, and much smaller than the leaves on the young shoots; the latter are broad, less deeply divided, and more rounded, but all of them taper much to the footstalks; they are downy on both surfaces, and more or less serrated at the apex of the divisions. The stipules

Leaves, 1½ inch broad and 1¼ inch long, including the footstalk.

are rather broad and crescent-shaped, with acute serratures on the outer edge.

The flowers are rather large, white, very fragrant, and produced in compact corymbs in June. The fruit is large, globular, of a yellowish-red or coral colour, and the sweetest of all the eastern thorns; indeed, when ripe, in the end of August and September, it is very agreeable to eat. It is produced in close clusters in great abundance, in consequence of which, and its brilliant colour, it becomes very ornamental during the autumn, as it remains on until destroyed by frost.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Old Acacia in the Jardin des Plantes.—The oldest tree in this garden, the patriarch of the Acacias, called the Old Robinier, whose death was expected twenty years ago, has again resisted the cold of last winter, and a shoot has sprung out from its trunk (on which there is no bark, and which is encased in zinc), and is thriving well. This tree was brought from America, by Vespasian Robin, arborist to Louis XIII., 237 years ago.

Extracting Tree Stumps.—A Guildford correspondent of the *Mount Alexander Mail* has practised successfully the following method of removing the stumps of trees from the ground:—He sprinkles on the tops of the stumps from 6d. to 1s. worth of kerosene, and, as the stumps are seamed, weather cracked, or decayed, it soon disappears. On the top of the stumps he piles the refuse wood, and after two or three days sets fire to them, and they burn completely up, roots and all. A lad can do the work, and have scores on fire at once.

Old Oak.—There is a magnificent old oak on the Montravail estate, near Salutes. The old tree is quite hollow, but still verdant and glandiferous. On the south side there is a kind of door, and the Druidical hall inside is large enough to receive a dozen visitors to be seated on stone benches arranged around a kind of round table. M. Dorbigny, according to the approved method, boiled a sectional portion of the timber in oil, and by calculations, based on analogy, and the virtual diameter of the trunk, concluded that there were more than 2,000 rings, i.e., that the forest monarch had passed his two thousandth anniversary.

Singular Enclosure in a Tree.—A Minnesota wood-chopper hewed down a tall tree the other day, and, upon splitting up the trunk with an axe and wedge, found imbedded in the wood at a point where the trunk diverged into branches, a leather bridle of antique pattern, with bit and buckles attached, and all in a remarkable state of preservation. It has been fully thirty feet from the ground, and its presence there can only be accounted for by the supposition that some passing horseman had used the crutch of a sapling as a rest for his bridle, and, led from the place in pursuit of his straying horse, had been unable to find it again, and abandoned the bridle to be carried up and entombed by the slow growth of the tree. It is believed that the tree must have been fifty years in hiding its treasure.

Himalayan Seeds.—Having received the following seeds from the Himalayas, will you tell me how to deal with them? especially No. 6:—1, *Cedrus Deodara*; 2, *Abies Smithiana*; 3, *Pinus excelsa*; 4, *Pinus Pindrow*; 5, *Cupressus tortuosa*; 6, *Rottlera tinctoria*.—**GUILFORD.**—[The coniferous seeds should be sown at once in a light sandy, rather dry loam, and placed in a cool situation, such as in a garden frame with its back turned to the sun, shaded by a mat, and merely kept moist until they begin to grow. The *Rottlera tinctoria* is a stove shrub, the seeds of which require to be sown in heat.]

THE GARDENS OF ENGLAND.

CONIFEROUS TREES AT ELVASTON CASTLE.

ELVASTON originally possessed few natural advantages. Mr. Barron, in his "British Winter Garden," however, says, "in August 1830 I found it to possess one feature which I had neither the power nor the wish to alter." This consisted of two avenues, planted, I believe, at the suggestion of the celebrated Capability Browne, who, on meeting, by appointment at Elvaston, the grandfather of the present Earl of Harrington, somewhat startled his lordship by telling him "that it was well, and he would let well alone;" upon an explanation being demanded, he said that the place was so flat, and that there was such a want of capability in it, that he would not meddle with it, at the same time presenting to his lordship six Cedars of Lebanon, and proposing that they should be planted on the east side of the mansion. They have now grown to be large, handsome, well-proportioned trees, and form, I need scarcely say, a fine feature near the castle.

It is now upwards of a quarter of a century since I first visited the gardens and grounds of Elvaston, where I spent an agreeable day with Mr. Barron, admiring choice bits of landscape, and discussing the merits and demerits of the numerous rare conifers then planted there. At that period there were few, if any, places in Great Britain, which presented so many attractions, not only to arboriculturists and horticulturists, but also to men of taste and refinement in all ranks of life, as Elvaston. The place had then been but recently formed. Lord Harrington wanted to have a garden "second to none," and in Mr. Barron he had an accomplished and able assistant, of whom it might truly be said, "he was the right man in the right place." Large trees had been brought from all parts of England, and Mr. Barron's now well-known tree-lifting machines had been increased in size and power to suit the demands made upon them. An extensive artificial lake and a series of rockworks had been formed, of which the late Duke of Wellington said, "they were the only good imitations he had ever seen." In laying out the grounds, according to well-conceived designs, an immense quantity of evergreen trees and shrubs had been planted, particularly conifers, all of which had been used with much taste and judgment; indeed, no labour nor expense had been spared to make Elvaston what it then was—the wonder and admiration of all who saw it.

On a recent visit to Mr. Barron, at Borrowash, he kindly offered to drive me to Elvaston, an offer which was gladly accepted. Twenty-five years have rolled away, and again the gates of Elvaston are passed. The scene is changed: perhaps there are more shadows on the landscape, now the small trees have become large and the large ones larger; but the high keeping everywhere then apparent is not now so conspicuous; the fairyland is exchanged for ordinary pleasure ground; yet, not ordinary, for at every step, here, there, and everywhere, noble specimens of conifers, and other exotics from many lands, ever and anon present themselves, dressed in adult habit, telling us far more forcibly than words can do, that they are at home, and mean to become permanent denizens of these islands. Soon after our arrival we were fortunate enough to meet with Mr. McKellar, the enthusiastic and intelligent young gardener who presides over the garden establishment there, and who kindly showed it to us. During a somewhat hurried visit, I noted the following conifers as being likely to prove useful, either as ornamental or timber trees:—

The Douglas Fir (*Abies Douglasii*): In great numbers, from 60 to 70 feet in height; coning abundantly, which few of the newer conifers are doing this season; in perfect health, except where much exposed, or where the tops rise above the surrounding trees.

Menzies' Spruce (*Abies Menziesii*): From 40 to 50 feet high; in fine health, although not growing with the vigour, and wanting that rich silvery appearance which it has in more elevated and mountainous situations, particularly when the soil is rich and deep.

The Eastern Spruce (*Abies orientalis*): About 25 feet high; this is likely to prove of more importance as an ornamental than a timber tree. In a deep, damp soil, it is very beautiful,

and forms a fine lawn or avenue tree; in thin, poor soils, it soon becomes scraggy and unhealthy.

Chili Pine (*Arucaria imbricata*): From 30 to 40 feet in height. This unique tree has long been associated with Elvaston, where, except the fine specimen at Dropmore, perhaps the finest in England used to grow. The severe winter of 1861-62 injured some of the best specimens, but many remain in perfect health, some of which are bearing a few cones this season.

The Deodar (*Cedrus Deodara*): From 40 to 50 feet in height. Likely in good localities to prove a timber tree, and, wherever it thrives, a really ornamental one. It is seldom seen fine in exposed situations, or in very poor soil. At Elvaston it is generally healthy, and still retains a habit distinct from that of the Cedar of Lebanon, which, in its adult state, it is said to very much resemble, if it does not prove to be altogether synonymous.

Japan Cedar (*Cryptomeria japonica*): From 30 to 40 feet high. This species is somewhat more spreading than many other conifers, the diameter of its branches being equal to about half its height. The tree has a very distinct and pleasing appearance, and forms wood freely.

The Cephalonia Silver Fir (*Picea cephalonica*): From 30 to 40 feet in height. This fine species is to be seen here in fine health, although slightly spring-tender when young; consequently, it should be grown in a shaded situation till it reaches above the frost line, four or five feet in height; afterwards it is quite hardy; even here, in this inland county, no indications are to be seen of its suffering from late spring frosts. As a timber, as well as an ornamental tree, this fine fir is likely to prove really important.

The Noble Silver Fir (*Picea nobilis*): From 40 to 50 feet in height. At Elvaston, as almost everywhere else, this grand tree stands out conspicuously; its massive pyramidal form, and rich blue-green and glaucous hues, at once arrest the attention of even the untutored, as well as the cultivated eye; and, when seen in full health, loaded with large cones, it leaves an impression such as few other trees do. For an avenue it is one of the most beautiful conifers in cultivation. This species should be used by all who are engaged in planting, whether for ornamental purposes, nurseries, or timber trees; the grandeur of its appearance, the rapidity of its growth, and its adaptability to our soil and climate will always justify such a procedure.

The Spanish Silver Fir (*Picea Pinsapo*): From 30 feet to 35 feet in height. This beautiful and well-known species is growing here with unusual vigour, and although it forms wood somewhat slower than its congener the *P. cephalonica*, it is a still more valuable ornamental tree, which should be planted wherever such is an object.

Nordmann's Silver Fir (*Picea Nordmanniana*): Mr. Barron specially directed my attention to the original specimen of this first introduced to this country, and which was sent to him about thirty years ago, with a plant of *Pinus Strobus nivea*, by Mr. Frederick, then amanuensis to the late Mr. Loudon. It was three years at Elvaston before the late Dr. Lindley would admit that it was in the country. Owing to the plant having encountered a series of accidents it is not now much more than twelve feet in height, but it is in perfect health.

Black Austrian Pine (*Pinus austriaca*): A dark-looking, strong-growing, extremely hardy tree, likely to prove invaluable for planting as a nurse or for forming a background in exposed situations. As a timber tree it is not likely to prove of much value, owing to its forming so many large branches.

Cembrian or Swiss Pine (*Pinus Cembra*): This grows here from 35 feet to 45 feet in height, is very healthy, and appears to luxuriate in the deep loamy soil of the district.

The Bhotan Pine (*Pinus excelsa*): From 30 feet to 40 feet high. This pine, in general appearance, somewhat resembles the Weymouth Pine, but is larger in all its parts, and less formal and regular in its habit. It is very fastidious as to soil and situation; here it forms a fine tree.

Lambert's Pine (*Pinus Lambertiana*): From 30 feet to 40 feet high. This species, like the *P. excelsa*, is somewhat fastidious as to soil and situation; where it succeeds well, it is a noble tree. At Elvaston it thrives tolerably well, and is likely to form a grand tree.

Corsican Pine (*Pinus Laricio*): From 50 feet to 60 feet in height. There are perhaps none of our recently-introduced coniferous trees which are found to thrive in such a variety of soils and situations as the Corsican Pine; as a nurse or timber tree its importance can hardly be overrated.

Pinus macrocarpa: From 40 to 50 feet high. Because this fine tree does not thrive—indeed, will scarcely live—in some parts, an opinion, held by many, that it is not hardy prevails to some extent. A visit to Elvaston will at once remove this impression; there it is to be seen in fine health, and generally this is the case when grown on a rich, deep, rather damp, than dry soil, particularly where the situation is moderately sheltered.

Tartarian Pine (*Pinus Pallasiana*): From 30 feet to 40 feet in height. A fine hardy strong-growing tree, with dark shining leaves, growing in a great variety of soils, but thriving best in a warm deep loam. It does well at Elvaston, and promises to be a useful timber tree.

Heavy-Wooded Pine (*Pinus ponderosa*): From 40 feet to 50 feet high. This noble tree, like the *P. macrocarpa*, prefers a deep strong soil, and where it succeeds is an object of great interest. At Elvaston it is in fine health.

Pyrenean Pine (*Pinus pyrenaica*): From 30 feet to 40 feet in height. This is a hardy free-growing species, with dark green glossy foliage, and reddish-yellow bark on the young growths when matured; altogether a useful tree, whether planted for ornamental, nursing, or for timber purposes. It thrives in all moderately good soils; at Elvaston it is in perfect health.

Variegated Pinaster (*Pinus Pinaster variegata*): There are two or three of the finest specimens of variegated Pinasters here I have ever seen; in most cases the variegation is irregular and limited in amount, and, as the tree extends its growth, is often thrown off altogether; here it predominates, and is said when in full leaf to have a fine appearance. The trees grow within a short distance of the mansion and should be observed by visitors, being conspicuous among the many rarities which enhance this interesting domain.

Taxus baccata aurea: Those who have any doubt about the wonderful effects on landscape produced by variegated plants should see what is done by means of the variegated yew at Elvaston, where it is extensively and most successfully used to light up and relieve the darker evergreen masses with which it is associated. At this season of the year it is remarkably fine, and probably the wet season has had something to do with its unusually rich appearance.

I would have liked to have said something about the numerous old yews, which have been brought here from great distances, some of them many centuries old, and each having an interesting history of its own, linking the present with the past, and giving an interest to the place which it could not otherwise possess; but I prefer that some one else should undertake the task.

I have now only to express a wish that others may meet as hearty a welcome, and enjoy the rich arboreal treat which Elvaston presents, as much as I did, when they visit this still fine place.

ARCHIBALD FOWLER.

Castle Kennedy, Wigtonshire,

Allotment Gardens at Coventry.—There are from eight hundred to one thousand gardens around Coventry, from about one eighth of an acre and upwards to an acre each, some few being larger. They are sought after and much prized by their occupiers, as they afford them much healthful relaxation and pleasure, besides adding in no small degree to the healthy condition of the inhabitants generally, a fact borne out by the low death-rate of Coventry, as compared with many other large cities, Coventry being generally third in the Registrar-General's quarterly report. The walks between the gardens are much frequented.—D.

"A FEW days ago," says the *New York Daily Bulletin*, "some of the most sentimental brokers doing business upon the Stock Exchange made up a pool of a small amount, by subscribing 25 cents each, for the purchase of a terra cotta vase, which was placed upon the large table in the Exchange, to be filled with fresh-cut flowers every morning by Mr. Alexander Stewart." The entire arrangement, in fact, was made at the instigation of Mr. Stewart, who has adopted this method of humanizing the board. It is stated that the brokers readily handed in their contributions, particularly the young ones, many of whom remarked that the flowers would remind them of the green fields of their youth, and of the days when they were young and innocent.

PUBLIC GARDENS.

THE VILLA PAMPHILI DORIA, ROME.

BY NOEL HUMPHREYS.

THE Villa Pamphili Doria is one of the most important of the many villas which embellish the suburbs of Rome. Its attractions are perhaps superior to those of the famous Villa Borghesi, though its greater distance from the central parts of the city, and the reputed unhealthiness of its situation, causes it to be much less frequented as a popular promenade. Most of the villas of the Roman nobles are open to the public, the customs of ancient Rome being followed by the rich denizens of the modern city in that respect. The gardens of the stern Sylla were free to the citizens of Rome, as were the more luxurious and splendid ones of Lucullus; and

highly-decorated gardens which they created having been thrown open, with very few restrictions, to the public.

The Villa Pamphili Doria was created by the wealth of Pope Innocent X. (a Pamphili), whose extraordinary devotion to Olimpia Maldachini forms one of the leading traits in his career. It is difficult to account for the great influence of this lady, except on the supposition that her intellectual powers were of a very high order, for her mere personal charms were certainly not remarkable, if we may trust the portrait which forms one of the chief objects of attraction in the small but select picture gallery of the elegant palazzo.

The entrance to the ornamental grounds, highly decorated with architectural dressings and enriched with statuary, commands a view of the palazzo, or rather palazzetto, which is a very elegant structure, though on a restricted scale. Its exterior is almost entirely encrusted with antique reliefs of

View in Gardens of the Villa Pamphili Doria, Rome.

Shakespeare has made Mark Anthony tell us how those of Cæsar were bequeathed to the public:—"Here is the will: and under Cæsar's seal," says the speaker, addressing the citizens, over the body of Cæsar,—

"He hath left you all his walks,
His private arbours, and new-planted orchards,
On this side Tiber: he hath left them to you,
And to your heirs for ever; common pleasures,*
To walk abroad, and recreate yourselves."

The Popes, who were the modern Cæsars, were, as a rule, the creators of the most beautiful casinos and villas that embellish the suburbs of Rome, and they have been scarcely less generous than the great Dictator himself, nearly all of the

exquisite workmanship. So exquisite are many of them that one cannot but regret that such unique and remarkable specimens of ancient art, of the very highest class, should be thus exposed to the gradual but certain destruction which exposure to the action of weather and seasons, even in the soft climate of Rome, will eventually insure.

The extensive grounds of this elegant *delizia* are extremely beautiful, and from one part there is a distant view of St. Peter's, with a foreground of green slopes studded with stone pines, aloes, and evergreen oaks, which few of the landscape painters who visit Rome omit to transfer to panel or canvas. Many of the alleys and shrubberies remind the visitor of the famous Bosquet of Versailles, as do the finely designed fountains, though on an infinitely smaller scale. The casino or palazzetto itself also recalls Versailles, and one cannot help feeling that the chief architect of the enormous palace of the

* Pleasures, or Plaisances; that is to say, pleasure-gardens, as distinct from orchards and vegetable gardens.

great French king must have very closely studied its architecture during his stay in Rome, and have taken away with him careful sketches of the palace summer-house of the Villa Pamphili Doria.

The groups and groves of stone pines, those picturesque firs of the south, are among the most distinctive features of these elegant park-gardens; and in late autumn pleasant picnics are often formed beneath them, when many (almost too many) *fiasechetti* of Orvieto wine are emptied, to which the nibbling of the delicious *pinelli*, (the kernels of the fallen cones) forms a pleasant accompaniment. I remember such a party, I will not say how many years ago; but it was when Gregory XVI. was Pope, and we were all very merry, very witty, and a very enthusiastic party, the hours then passed were very sweet ones, but their recollection is bitter, for few now remain of those who made them so pleasant.

LADY CORISANDE'S GARDEN.

"How I hate modern gardens!" said St. Aldegonde. "What a horrid thing this is! One might as well have a mosaic pavement there. Give me cabbage roses, sweet peas, and wallflowers. This is my idea of a garden. Corisande's garden is the only sensible thing of the sort."

"One likes a mosaic pavement to look like a garden," said Euphrosyne, "but not a garden like a mosaic pavement."

"The worst of these mosaic beds," said Madame Phœbus, "is, you can never get a nosegay, and if it were not for the kitchen garden we should be destitute of the gayest and sweetest of creations."

"Corisande's garden is since your first visit to Brentham," said the Duchess to Lothair. "No flowers are admitted that have not perfume. It is very old-fashioned. You must get her to show it you."

It was agreed that after breakfast they should go and see Corisande's garden; and a party did go—all the Phœbus family, and Lord and Lady St. Aldegonde, and Lady Corisande, and Bertram, and Lothair.

In the pleasure ground of Brentham were the remains of an ancient garden of the ancient house that had long ago been pulled down, when the modern pleasure grounds were planned and created. Notwithstanding the protests of the artists in landscape, the father of the present duke would not allow this ancient garden to be entirely destroyed, and one came upon its quaint appearance in the dissimilar world in which it was placed as you might, in some festival of romantic costume, upon a person habited in the courtly dress of the last century. The duke had given this garden to Lady Corisande, in order that she might practice her theory, that flower gardens should be sweet and luxuriant, and not hard and scentless imitations of works of art. Here, in their season, flourished abundantly all those productions of nature which are now banished from our once delighted senses; huge bushes of honeysuckle, and bowers of sweet peas, and sweet briar, and jessamine clustering over the walls, and gilliflowers scenting with their sweet breath the ancient bricks from which they seemed to spring; there were banks of violets which the southern breeze always stirred, and mignonette filled every vacant nook. As they entered now, it seemed a blaze of roses and carnations, though one recognised in a moment the presence of the lily, the heliotrope, and the stock. Some white peacocks were basking on the southern wall, and one of them, as the visitors entered, moved and displayed its plumage with scornful pride. The bees were busy in the air, but their homes were near, and you might watch them in their glassy hives.

"Now, is not Corisande quite right?" said Lord St. Aldegonde, as he presented Madame Phœbus with a garland of woodbine, with which she said she would dress her hair at dinner. All agreed with him, and Bertram and Euphrosyne adorned each other with carnations, and Mr. Phœbus placed a flower on the uncovered head of Lady St. Aldegonde, according to the principles of high art; and they sauntered and rambled in the sweet and sunny air, amid a blaze of butterflies and the ceaseless hum of bees.—"*Lothair*."

Meetings in the Parks.—Henceforth, in all parks under the management of the Commissioners of Works, including Holywood and Linlithgow, no one will have the semblance of right "to deliver, or invite any person to deliver, any public address, except in accordance with the rules of the park, which rules are to be first laid before Parliament." It is understood that, in accordance with this provision, certain spots will be set apart for public meetings, and anyone addressing public meeting held in any other part of a park will be liable to a penalty of five pounds.

VEGETATION IN TOWNS.

BY WILLIAM HINDS, M.D., &c.,

Professor of Botany, Queen's College, Birmingham.

ONE of the first facts we have to meet is that we supply plants and trees with a positively enormous quantity of food—that class of food from which nearly all the solid parts of plants and trees are derived. I do not refer, of course, to the water or to the ammonia, but to the carbonic acid, which must be furnished in the water. Professor Herepath estimated that about 12.7 oz. of carbon are daily converted by an adult into carbonic acid. Professor Helmholtz estimated the amount as on an average about 16 oz. Now 12.7 oz. produce, when oxidised into carbonic acid, about twenty-five cubic feet, and 16 oz. would give more than thirty cubic feet. The human beings in Birmingham alone number about four hundred thousand, if not more. This, without counting animals, would give us twelve million cubic feet per diem of carbonic gas for Birmingham. But this is far from the full aggregate, for we have to add to this sum that which is produced by every gaslight, every fire, and every other full oxidation of carbon. From fifteen million to twenty million cubic feet of carbonic acid must then be produced daily in this large community. A second fact is that this gas, which feeds the plants and trees, is a deadly gas so far as animal life is concerned, and must be got rid of effectually if we are to live and breathe, and retain and enjoy health. Nay, even when diluted with 80 per cent. of common air it is fatal to animal life. A dilution to the extent of 90 per cent. with common air gives a mixture injurious to animal life, and cannot be breathed without injury. What, then, becomes of this enormous sum of fifteen million or twenty million cubic feet of carbonic acid produced every day? No doubt it becomes gradually diffused; and well it is so, or we could not live a single hour in our ordinary circumscribed atmosphere. It must be thus partially removed from the sphere of animal respiration, but it is not effectually done, or even half done, under the present arrangements of society; and decadence of health too often from this unsuspected cause results. But, even when diffused, it is not destroyed. It still exists in the atmosphere, especially in the neighbourhood of and in crowded communities, and it can only be effectually got rid of by vegetation, and vegetation on a large scale in and in close proximity to towns. A third fact now meets us, namely, that we in towns are doing all we can to kill the very agents on which we depend for our lives and our health. Animals die without a constant supply of oxygen; vegetables die without a full and free supply of carbonic acid. Every city and every town in this kingdom is, however, engaged in the process of suffocating plants with their smoky and intolerable atmospheres. The moment any plant is introduced, a gradual process of suffocation commences, and this is followed in some cases by rapid death, or, if not, by a sickly decadence. This is as effectually done as if animals were prevented from exhaling the carbonic acid from their lungs, either altogether, or else partially prevented, as human beings are when they breathe an atmosphere previously contaminated with five, ten, or twenty per cent. of this deadly excrementitious substance; or when the larynx or bronchial tubes are physically obstructed. But for this one condition, we might have plants and flowers and trees growing in every locality, or in every corner of this crowded town, and these would relieve the inhabitants of the refuse and deadly acid which is often so unsuspectingly hurtful or fatal to health. The breathing or respiratory mouths of the leaf, on the average, number, we may calculate, about sixty thousand on every square inch of the under surface, or sixty times as many as the sudoriferous pores of various portions of the human skin. A fairly large leaf of the rhododendron would give about ten square inches of surface below. We should thus get in one leaf on its under side alone about six hundred thousand pores, and which excrete oxygen, and act as ordinary exhalents. These breathing and exhalent orifices are very small, and therefore much more easily obstructed by those minute particles which constitute the subsequent pellicle of smoke—soot. Smoke is, of course, sooty carbon in a very minute state of division, and the more impalpable and fine the particles the more effectually does it cover the breathing pores with an obstructive if not impenetrable layer. The rain, even when free from soot, which indeed it seldom or never is, in towns, does not clear those pores, because the upper side of the leaf is much less abundantly furnished with pores than the lower. No doubt Nature arranged that in this way dust and dirt should not act so much as obstructions. But even dust and dirt merely would not very materially injure a plant exposed to light and rain freely, with the other known requirements. They are not like the thin penetrating fatal film deposited by smoke. To a certain extent the trees in all our very immediate suburbs, which are evergreen, or retain their leaves through the winter, may be shown to have a slight deposit of smoke, not so much, however, in the suburbs as to very severely injure the plant. Leaves in the botanic

garden at Edgbaston, just a mile from the centre, will be found somewhat contaminated, and the smoke may be wiped off or washed off. Some plants are like delicate children, and the first decadence is perhaps one of rapid death. Other plants are hardy or less tender, and seem resolved apparently to die hard. It is a question of degree and variations in the several conditions; and none of the facts at all subvert those relentless conditions and laws by which the Allwise Creator has accomplished His wonderful designs and will. What can be done? What remedies have we in our power? These are multitudinous; but we have many questions to deal with as to sanitary laws. The dense accumulation of people in a very large town produces much poverty, disease, death, squalor, filth, and other evils. Surely it could never be intended by nature that human beings should collect themselves and their habitations so closely together as to shut out life often, and especially the means of breathing an atmosphere consistent with life, and even seeing something of the other works of nature besides themselves. The dense accumulations of large towns is a fatal mistake, and a fatal evil. Gradually this dire evil must practically force itself upon the notice of civilised nations, and in spite of the overbearing tendencies to concentration, the future policy of every wise people will perhaps inevitably be, and certainly should be, dispersion, and thus further the aim of the Creator when He made the world of life strictly relational in its departments, and left the intelligence of His creatures to find out and carry out His all-wise, beneficent, and sovereign will.

THE CLOTHING OF COTTAGES.

Few things are more incongruous in landscape scenery than the garish glare of a new cottage, or the bald walls or bare tiles of an old one. Cottages are frequently indispensable as lodges, gardeners' residences, and even for ornament. But it is comparatively seldom that they are well managed, and made to fit in to and even contribute to the richness and beauty of a landscape. In most cases they are planted, or rather smothered out. A thick blind of trees and shrubs is got up to shut out the cottage and shut in the inmates. This renders a dwelling unwholesome, and also deprives a landscape of a very enjoyable feature, that of habitability, if I may so call it. The rising smoke from the chimneys, the light and sound of living beings, all add new features and charms to a landscape. Hence, where cottages exist, within or near the grounds belonging to an estate, they should be made worthy of the position, and made to harmonise with it. Sometimes a slight or considerable change in the buildings themselves will be needed; a new front or end, or chimney, a tower, rustic or otherwise; a flagstaff, a castellated roof, or a gable end, &c. In others, nothing is needed but the judicious clothing of the walls with ivy, clematis, roses, jasmines, &c., as in our woodcut. A few trees planted, and a rustic fence, as here shown, are very effective. This mode of partially revealing the house is very pleasing. The walls, roofs, and chimneys even can be wreathed or embowered in green, contrasting charmingly with the windows and their white blinds. Lodges seldom look so well as when treated in this manner. They thus form a green link, alike refreshing and pleasing, between the dusty public road and the finely

Gate Lodge at Smeethleyton, ornamented with Climbers.

timbered park and polished pleasure-grounds of the country mansion. It would be well for the health, comfort, and happiness of many gardeners, as well as for the further adornment of many charming landscapes, were gardeners' houses removed from the back sheds, where so many of them are placed, and erected, as features of interest and beauty, on some of the best spots of the pleasure-grounds. D. BURY.

THE INDOOR GARDEN.

THE BLUE LESCHENAUTIA.

ALTHOUGH this is one of the finest and most generally admired of greenhouse plants, and one which, when well managed, remains in beauty longer than most of our greenhouse favourites, yet it rarely happens that we see it in anything like perfection. It is a first-class plant for decorative purposes, as well as one of the most effective for exhibition; and no plant with which I am acquainted better repays the trouble necessary to manage it properly. There are two varieties of it in cultivation, the best of which is known in the trade as biloba

major; and I would advise persons commencing its culture to procure that kind in preference to the other, for its blooms are larger and produced more freely under similar treatment; both, however, are beautiful plants, well deserving a place in every collection.

In commencing the culture of this plant, procure nice young specimens from some nursery, and in selecting them, choose such as have a clean healthy appearance, and are strong and stocky and not over-potted. As soon as the plants can be procured, they should be repotted and placed in an intermediate house where a temperature of from 50° to 60° is maintained, placing them near the glass and encouraging growth; give air on the sheltered side of the house

on every favorable opportunity, but avoid ventilating so as to cause dry cold currents. As they progress, attend to stopping the stronger shoots and tying out the branches as may be necessary to secure a compact regular growth. Plants obtained in March, and which have done well, will be ready for a second shift by this time, and if all goes well, the plants will have taken to their second shift by the middle of August, and will then be nice half specimens.

To prepare these to stand a damp and sunless winter must now be attended to. They should be gradually exposed to a free circulation of air, removing them to a cool dry house for a week, and then placing them out of doors for a fortnight or three weeks, which will ripen and harden the wood and render them much less liable to suffer from damp during the winter; while out of doors they must be laid on their sides if heavy rains occur, and be carefully watched, so as to guard against the soil getting saturated, and, if wet weather should set in, the plants had better be placed under glass, allowing them all the air possible. During winter they should be placed in a cool house where the temperature will not exceed 40°, keeping them near the glass and giving air whenever the weather will permit; but this should not be done so as to cause currents of cold air to rush through the plants. Except on very mild days air should be given on the sheltered side of the house only; drip, too, must not be allowed to fall on the plants. If, during damp weather, the foliage shows any tendency to fog off, a little fire-heat should be applied, giving air at the same time to dry the leaves.

Treat the plants the second season exactly as has just been recommended, taking care to stop any over luxuriant shoots, and to put them nicely into form before starting into growth in March. By the end of the second season they will be fair-sized specimens, and should be placed out of doors early in August; for, unless the young wood is ripened, there will be little chance of their blooming. In my opinion it is better to have a moderate-sized plant covered with bloom than one twice as large with only a few straggling flowers on it.

The soil in which I have found this plant to do best is good fibrous peat, nicely broken up, mixed liberally with silver sand. Care should be taken to have the ball in a properly moist state, and also the fresh soil in as nearly as possible the same condition as to moisture; the new soil should be regularly and rather (but not over) firmly pressed about the ball. Care should also be exercised to secure perfect drainage, and this should be done by nicely arranging a moderate quantity of thin crocks and covering them, so as to effectually prevent the fine soil from stopping up the drainage.

I have said nothing about watering, but the proper application of this is a very important point with respect to securing success in the culture of this plant. When in an active growing state, a liberal supply is required, but the soil must never be saturated; and, when the season's growth is completed, the plant should be very sparingly supplied with water; and, in winter, I find it good practice when the plants are dry to place them for an hour in a pan filled with water, so that the crocks may be covered. This feeds the active roots and moistens the bottom soil without saturating the mould towards the surface where the thick fleshy roots are, and which are liable to suffer from excess of moisture at any season, particularly in winter. I have also said nothing about shading during summer, but I suppose that nowadays I need not say that it would be hopeless to expect vigorous growth from a plant exposed to the full influence of the sun's rays in a dry atmosphere deprived of the health-giving influence of night dews. I need hardly state, likewise, that if free rapid growth is expected shading must be applied as early in the season as the weather, &c., may render advisable, and constant care must be exercised to maintain a moist atmosphere during dry weather. This should be done by sprinkling the passages and not by syringing the plants overhead, which ought only to be done during the summer months, and then only in the evening and when the weather is very bright and dry; and neither shading nor moisture should be used in excess unless large plants without bloom should be desirable.

W. M.

STAPELIAS, THEIR CULTURE AND THEIR PECULIARITIES.

READ BY J. CROUCHER, AT THE BIRMINGHAM CONGRESS.

To attempt to interest and instruct with a few notes on these old garden favourites may appear to some like a retrograde movement in these days of Cattleyas, Odontoglossums, and Masdevallias; yet there are those in the horticultural world who, like myself, are pleased to hear of old plant friends; I, therefore, venture to say a few words about Stapelias.

Natives of the Cape of Good Hope, Stapelias are greenhouse subjects. Though easily grown many fail with them, saying they grow well for a time, and then decay. This I attribute to the climate they come from not being understood, and the common practice of taking it for granted that as they get a dry season, it must be during our winter; so they are allowed to shrivel, the result of which is, that when they should grow in spring, the bottom often decays, and the plants get over it just in time to be served in the same way again. Now every observer of Cape plants knows well that they have a tendency to grow freely during our winter, and though this growth may be retarded it must not be arrested; therefore Ixias, Pelargoniums, and Heaths are exposed to all the light we can get, while the Stapelias are put on some out-of-the-way shelf. At the time we are getting our dulllest and coldest days the Stapelias at the Cape are getting their brightest and hottest; therefore we ought to give them all the light possible, and as much heat as is compatible with it. Like other Cape plants, they don't like fire-heat, therefore they should be kept as far from the pipes as convenient; they stand the winter and flower better, if exposed to the open air from June until September. It is best to strike fresh stock every season, taking the branches off at a joint to prevent danger of decay and escape of sap. April and May are the best seasons; put them in close to the edge of the pot, and keep them dry for a week, when water may be given; after which, give it when quite dry. If they are well exposed to the sun they will strike in three weeks. Seed should be sown as soon as collected, or its vitality will soon be gone. Sow in shallow pans in light soil, and put them on gentle bottom-heat; as soon as well up, put them on a shelf close to the glass, not potting off until well grown, as they often stand still for some time or die. Almost every one who has written on these plants recommend sandy soil for them, but I find they grow best in a solid soil. Three parts loam, and one broken brick, is the best, excluding sand or manure; in this soil, with small pots, they grow freely, and though we have one species called *S. europæa*, or *italica*, yet I have seen it luxuriating above its natural growth in a temperature of 100° Fahr. Seeds for transmission should

be put into sealed bottles, or oiled paper. The plants are very difficult to import; the best plan is by means of a small wooden box, using dry sand for packing material. I have seen many ways employed, the last of which was sugar; but when opened, I must say they looked anything but sweet. Many of the section *Orbea* do very well on rockeries in summer, but they won't stand frost.

For diversity of structure, and development of the flower, I think the different species of Stapelia are very interesting, and though modern botanists persist in quashing Haworth's divisions, I like them. If we allow Cattleyas and *Lælias*, or *Oncidiums* and *Odontoglossums*, to stand distinct, I think the Stapelias should also be separated. If we would study any set of plants minutely, we must have subdivisions. In a genus containing seventy—eighty species, the first thing asked concerning any one of them is, to what group does it belong? And to me it appears easier to say *Huernia* or *Orbea*, than subgenus *Orbea*, &c. In *Stapelia grandiflora* and *S. hirsuta* we have pubescent stems and hairy flowers, a five-partite reflexed corolla, the centre plain, and the corona which protects the stigma parted into ten lobes, five spreading outwards, the other five, which include the anthers, incurved. In the section *Orbea*, to which *S. variegata* and *S. bufonia* belong, the whole plant is glabrous, the corolla is reflexed, and round the centre is a raised part, resembling the top of a leaf, the corona is raised in elegant tiers, like that of a crown, distinct from the former. In *Huernia* we have a campanulate corolla, cut into ten segments at top, the inside clothed with glandular hairs, and the corona spreading like teeth; the arrangement of the ligules give interest to each section.

It is a well-known fact that these plants evolve a strong carrion-like scent, and the common blowfly, being deceived thereby, deposits, its eggs amongst the hairs of the flowers of *S. hirsuta* and the allied species, in which section the scent is strongest; but I have not noticed them in the smooth kinds. As soon as they are hatched they begin to search for food, and, as a matter of gravitation, go down hill. The pollen masses being clammy, and the aperture leading to the stigma being so small, the pollen couldn't possibly get to the stigma unless by artificial aid; here the maggot becomes of use: the source of the scent being the stigma, the maggot, in its endeavour to get down the aperture, forces the pollen into the stigma, and thus fertilises it. This I have watched often with much interest; here also we see the use of the hairs—were it not for them the young maggots would get blown away by the winds. It may be asked, how do those get on that have no hair? On examining them, it will be found that the apertures are larger. It has been said that Stapelias are not fertilised by the pollen of the same flower, but I have seen seed on a plant that had but one flower, and the seedlings came true.

The species called *S. europæa* is said to be a native of Europe, but I have often received it from South Africa, and I know of no plant, excepting our own thistle, more likely to cross the sea during a storm of wind.

THE FRUIT GARDEN.

FRUIT TREES IN PLEASURE GROUNDS.

BY PETER GRIEVE.

It may be said with truth that there are few objects more beautiful and interesting during the spring or early summer months than our common cultivated fruit trees: and there really does not appear to be any good reason why the fruit garden should not constitute a necessary portion of the policy or pleasure grounds of every country mansion. What can be more beautiful than the apple, the pear, the plum, and the cherry tree in full flower? And they are, in fact, exceedingly interesting objects at all seasons. But it rarely happens that they are placed in positions where their beauty can be appreciated and enjoyed. They are too frequently to be found in the vegetable garden, where they are entirely out of place (unless it be in the form of espaliers or cordons), or they may possibly be found in a somewhat neglected and out-of-the-way locality known as the orchard. But as an advance or an improvement upon this state of things, might not these useful and ornamental trees be cultivated with more pleasure, and at least equal profit, in a tastefully-designed garden or compartment by themselves, and forming at the same time an essential part of the pleasure grounds? Clumps or groups of varied forms and dimensions could be formed of pyramidal or otherwise trained apple, pear, plum, and cherry trees, &c., which might be margined by low single cordons of their respective kinds, while single standard trees of various sorts might in suitable situations be allowed to assume their natural habit and dimensions—the whole area to be traversed by winding and comfortable walks, to afford every facility for the examination and enjoyment of the beauty of the various fruits in all stages of their development. Altogether I am inclined to think that by adopting some system of grouping such as I have endeavoured to describe, and by adhering to an arrangement which would associate the fruit garden with the pleasure ground in such a manner as to constitute, as it were, a necessary and important portion of the same, and to some extent effect a combination of the *utile* with the *dulce*, we could hardly fail to give additional interest to the surroundings of a country mansion or residence at all seasons of the year.

Orchard Houses.—I have been often asked why I insist so much on solid soil for fruit trees. There is a good deal that is not included in our philosophy, but perhaps the reason is not difficult to find in this case. Loose rich soil is traversed easily by roots, and trees growing in it make strong vigorous shoots. Such shoots are not what we desire in fruit trees. Short-jointed, hard, well-ripened wood is what is requisite for fruit-bearing trees. Then, again, roots near the surface, within the reach of air and sun, are always considered necessary for the production of fruit buds and well flavoured fruit; whilst tap roots, striking deeply into the subsoil, are productive of strong and vigorous branches. Does it not follow that if the surface roots are injured by digging, the uninjured tap-roots will be encouraged? In most gardens I think much labour is worse than thrown away in digging, where the hoe and rake are the only tools which ought to be used. If fruit trees were planted in quarters by themselves, in place of being dotted about all over the kitchen garden, it would be a great improvement. My standard peaches, which are growing in soil as hard as a pathway, which has never been disturbed since they were first planted, now nearly twenty years since, are now full of fine fruit. These trees bore about fourteen dozen of fruit each tree last season, and are quite as full now, and have only missed fruiting once since they were planted.—*J. R. PEARSON, Chilwell.*

Nails in Fruit Trees.—We give the following from a Canadian paper, for what it is worth:—A singular fact, and one worthy to be recorded was mentioned to us a few days since by Mr. Alexander Drake, of Albemarle. He stated that whilst on a visit to a neighbour, his attention was called to a large peach orchard; every tree was totally destroyed by the ravages of the worm, with the exception of three, and these were most thrifty and flourishing peach trees. The only cause of their superiority known to his host was an experiment made in consequence of observing that those parts of worm-eaten timber into which nails had been driven were generally sound. When his trees were about a year old, he had selected three of them, and driven a tennenny nail through the body, as near the ground as possible. Whilst the balance of his orchard had gradually failed, and finally yielded to the ravages of the worms, these three trees, selected at random, treated precisely in the same manner with the exception of the nailing, had always been vigorous and healthy, furnishing him at that very period with the greatest profusion of the most luscious fruit. It is supposed that the salt of iron furnished by the nail is offensive to the worm, whilst it is harmless, or perhaps beneficial, to the tree. A chemical writer on this subject says: "The oxidation or rusting of iron by the sap, evolves ammonia, which, as the sap rises, will of course impregnate every part of the foliage and prove too severe a dose for the delicate palate of intruding insects." This writer recommends driving half-a-dozen nails into the trunk. Several experiments of the kind have resulted successfully.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Finchley Vine.—The old vine in Kay's nursery, at Finchley, is now in fine condition, and many interested in grape-growing would be much gratified in seeing it. Considering the usual size of the bunches, as well as the size of the vine, it is the most remarkable vine near London.

How to Save Strawberry Seed.—Procure some good blotting paper, on which mash your berries; the juice will be absorbed, and the pulp and seeds will remain on the surface of the paper. Place the latter in a dry sunny place, and in ten or twelve days your seeds will be perfectly dry and ripe. Then sow them very shallow in a nicely prepared bed, which must be kept moist. In from two to four weeks your plants will be up, when, as soon as large enough, they can be transplanted.

Influence of the Stock on Pears.—Some time ago, Mr. Tillery, of Welbeck, sent us some fine fruit of the Grosse Calabasse pear, as a sample of the change produced by the stock on the graft. "They were gathered," said Mr. Tillery, "from some grafts of the Calabasse put on a Beurré Superfin two or three years ago. It is well known that the Beurré Superfin is one of our best flavoured of pears; and in this instance it has communicated a better flavour to the Calabasse. I have sent likewise some specimens of the Calabasse grown in the same soil and aspect as the grafted ones, to show the long shape and the greenish russet that the Calabasse usually presents."

Saving Barked Fruit Trees.—The method is to graft five or six scions as large round as a goose quill, and long enough to reach over the girdled place into the tree. The live bark is first notched above and below the girdled portion, the sprouts spring into place, and the ends fastened with wax. These scions grow rapidly, and in time spread over the whole girdled surface. Apple trees completely girdled, and having the bark taken off over a foot in width on one side, have been saved in the above manner. Mr. Lemmel Town, of Nashua, New Hampshire, we believe, was the first to act upon and suggest to others the idea.—*Canada Farmer.*

Walls or Glasshouses for Pears, Plums, and Cherries?—I am building a house in the country, and propose to make a fruit and vegetable garden of about 1 to 1½ acre in extent, in form a parallelogram. Would it be advisable to enclose it with walls for my fruit trees? or would it be more profitable to expend the money I propose to lay out on glass houses? The fruits I am most anxious to have are pears and plums of various kinds, and cherries. Peaches and nectarines are too uncertain.—*DEVONIAN.*

Pears for the West of England.—Will you or any of your readers kindly advise me what kinds of pears are the best for planting in this part of England?—*S. K., Somersetshire.*—[Doyenné d'Été, Jargonelle, Williams's Bon Chrétien, Louise Bonne of Jersey, Comte de Jany, Conseiller à la Cour, Doyenné du Comice, Passe Colmar, Winter Nelis, Josephine de Malines, Easter Beurré, Bergamotte d'Espéran, Beurré Giffard, Beurré Superfin, Thompson's, Glout Moreceau, Knight's Monarch, and Ne Plus Meuris.]

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 54.)

PRUNING AND CUTTING-BACK.

In order to secure for plants grown in a room a symmetrical shape, it is necessary not only to place them near the light, but also to turn them from time to time, that the growth may not be all one-sided. With plants which have few or no branches, and are of slow growth, such as *Dracænas*, Palms, *Ficus*, *Yuccas*, &c., repeated turnings will be sufficient to produce a symmetrical shape. Bushy plants, the leaves of which fall off in consequence of too warm a position, or from want of light during the short dark days of winter, produce a quantity of rank shoots, some of which are long and others weak. These sometimes disfigure the shape of the specimen, and sometimes form no strong buds, so that at the commencement of the new growth in spring, they partially die off, and partially form a fresh feeble growth. In this case, in spring, before the new growth commences, the longest shoots must be cut back to a few buds, and all the small and weakly shoots should be removed entirely. But even when the growth is regular, pruning must be employed to secure a handsome shape, and all shoots which are too long must be cut back to a few buds. To what extent this is to be done will depend altogether on the shape which is to be given to the specimen. As a general rule it may be stated that, where long and strong shoots are required to complete the shape of the plant, the shoots should be cut back to two or three buds, and then only one or a few shoots allowed to develop themselves. The fewer the shoots which are allowed to grow on a branch the stronger they will be, while, on the contrary, the more there are, the feebler will their growth be; the same quantity of nutriment is in the one case conveyed to a greater number, and in the other case to a smaller number of shoots. Therefore, when a comparatively feeble or short growth is required, the shoots should be only slightly cut back. For the greater number of plants the best time for this operation is in the spring, before the new growth has commenced, and it may then be done at the same time when the plants are transplanted. There are some exceptions which are specially mentioned in the enumeration of plants for room-culture. When new shoots are formed on unsuitable parts of the plant, they should be broken off before they have grown too strong, as they will only obstruct the development of the other plants.

In addition to pruning for shape, it is that which has for its object the production of more abundant bloom. This is regulated by the peculiarities of the various kinds of plants, such as producing their flowers on ripened wood or on young shoots, their season of blooming, the parts of the plant on which the flowers appear, and various other matters which will be detailed at length in the enumeration of the plants. For summer-blooming plants this pruning is usually performed in spring, at the same time as the pruning for shape. The pruning of plants intended to bloom in autumn and winter will be fully noticed in the chapter on forcing. Some kinds of plants, and especially the continuously-blooming roses, should, after the first blooming in spring, be subjected to a second pruning in summer. This is done by cutting back the shoots which have flowered (usually to three buds), in consequence of which the plants make a second growth, and in the course of the summer flower again, and often better than the first time. The common monthly rose and the pretty dwarf *Rosa Lawrenceana* bloom almost uninterruptedly if the shoots are cut back constantly after blooming. The winter gilliflower also continues to produce fresh blooms for a long time if the shoots which have flowered are removed. The same is the case with many annuals.

Pinching the plants for the purpose of regulating the shape is a very different operation from pruning. This consists in pinching off the tops of the young shoots during the time of growth, in order to produce a thick bushy habit in the specimens. By preventing the development of the tops of the shoots, the buds in the axils of the leaves are forced into growth and form new shoots which may be treated in the same manner as soon as they have grown sufficiently long. The oftener this pinching

is repeated the greater number of shoots will be produced, and, in consequence, the plant will acquire a handsome full habit, a thing which every amateur knows how to value. Pinching is to be especially practised with plants of rapid growth, and with many shrubs from New Holland and the Cape of Good Hope, which, however, are seldom cultivated in rooms. Among the plants which are particularly benefited by it are Indian Azaleas, which, if carefully pinched when young, flower much more abundantly. The same may be said of Fuchsias, Heliotropes, Pelargoniums, Veronicas, Myrtles, &c. However advantageous this pinching may be in producing fine bushy specimens, it should not be continued longer than until the plants have acquired the desired form, as, so long as it is employed, the plants bloom but sparingly, or not at all.

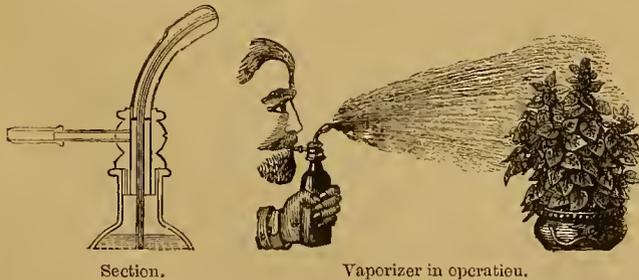

PROPAGATION BY MEANS OF SEED.—THE KEEPING OF SEED.

With regard to the duration of vitality in seeds, a great difference exists in different kinds, according to their organization. Some, even under careful keeping, soon lose their germinating powers, as the oak, the willow, and many seeds which are rich in volatile oil, as the nutmeg and most palms and conifers. These should be sown immediately when they are ripe, if it is expected they will germinate. Seeds which contain less oily matter preserve their vitality for a much longer time under otherwise favourable circumstances. Of this kind are the seeds of the various kinds of corn, the Cucurbitaceous and Leguminous plants. In the keeping of seeds so as to preserve their vitality, and, at the same time, not hasten their germination, the following conditions are necessary:—(1) A low temperature; for seeds of temperate and cold climates from 25° to 40° Fahr.; for those of warmer climates from 40° to 55° Fahr. (2) An atmosphere only very moderately moist. (3) Absence of sunlight, as under its influence the decomposition of the matter inside the seed is much hastened. (4) Free access of the air; therefore where seeds are kept in boxes or in heaps, they should be turned over from time to time. (5) Seeds that soon spoil should be kept in their seed-vessels until they are sown, or preserved in layers of dry earth or sand. (6) Avoidance of all influences which tend to excite germination, as a high temperature; or for seeds of tropical plants, the continuance of a very low one. (7) Seeds of water and bog plants, which naturally fall into water, should be kept in water.—*Dr. Regel.*

(To be continued.)

THE HORTICULTURAL VAPORIZER.

We have much pleasure in calling attention to this simple and efficient little contrivance. It is called by the inventors, Messrs. Parr & Atherton, of Nottingham, "the horticultural vaporizer." It is used for the application of Flettingham's Liquid Compound, or any liquid preparation used for the destruction of insect life. By means of it, liquids may be diffused over plants in a state of minute

division, or fine spray, in sufficient quantity to thoroughly moisten them, without wasting any of the liquid, the minuteness of the spray preventing a single particle of the liquid falling to the ground. The vaporizer may be used either by blowing, or by the use of a pair of bellows, fastened by means of a small piece of india-rubber tube to the mouth-piece of the vaporizer.

Table Decorations.—In a letter to the editor of the *Telegraph*, Mr. William Thompson says:—"In your report of the rose show at the Crystal Palace my name is mentioned as a defender of the practice

of 'cutting holes in the dinner-table' for the purpose of introducing plants without showing the pots in which they grow. Having so frequently acted as a judge of table-decorations during the last seven years, I hope you will allow me to state that I have neither proposed or approved of such a plan. What I do advocate is the use of properly-shaped plants as a part of the decorations of a dinner-table; and because the usual boxes, jars, covers, and other contrivances for hiding a flower-pot placed upon the table, so far as I have seen them, all fail to please my taste, I strongly support the plan advocated by Mr. Fleming, of Cliveden, of placing the pots under the table. This plan can be adopted without injury to any dining-table, either by allowing the plant to come up between the leaves of the table, which can readily be kept at the necessary distances apart by wood or iron straps fastened underneath, or by using extra leaves made specially for the purpose out of common wood. Four semi-circular glass or zinc troughs, arranged in two circles, one within the other, filled with moss, and tastefully decorated, form a base for the plant above the table-cloths, which is far more pleasing to my eye than any metal, earthenware, glass, or other art-product that I have yet met with. No stronger proof of the effectiveness of such arrangements need be instanced than the fact that, out of the ten prizes for table decorations which my brother judge concurred in awarding, five were given to tables which had young palms coming up through them. This, I repeat, can easily be done in any private house without cutting holes either in the table or in the table-cloths."

Liquid Manure for House Plants.—As liquid manure cannot always be had, especially in winter, dirty suds in which clothing has been washed will, I find, answer as well. I have used it all the winter, and my plants never grew so fast nor looked so well. I had this spring, a double Primrose in a three-inch pot, on which I could count over one hundred blossoms; also some bicolor and white Geraniums, started for spring planting, only three inches high, the leaves measuring four inches in diameter. My largest Calla stands three feet two inches high, leaves fifteen inches; also many other things, all of which I attribute to the use of my dirty suds once a week during winter. Last summer I watered all my roses with it, and the pillar Roses with dish water. The slugs scarcely troubled them, and the blossoms were really wonderful, both in quality and quantity. I never have any slops wasted. Bedroom slops are just the kind to throw around the roots of young trees; I think that is what saved our Mountain Ash last year from the borers; at any rate, it never does any harm to save all the slops for grape vines and hardy trees.—*S. J. H., in "Country Gentleman."*

GARDEN DESIGN.

HARTSFIELD, NEAR BETCHWORTH, SURREY.

HARTSFIELD, of which we this week furnish a plan, was, three years ago, merely fields cut off from one another by the ordinary hedges of the district, and containing here and there an occasional tree or two. By the removal, however, of old boundaries, and the working in of the existing trees, together with some new planting, a very charming little place has been formed. The mansion is placed on the summit of a knoll, commanding in every direction views of the most charming description; the beauty of the grounds is, therefore, to some extent lost, owing to the impossibility of representing on a flat plan the pretty undulations which they contain; a difference of nearly seventy feet exists between the lowest point on the carriage road and the site of the dwelling-house.

Advantage has been taken of a small tributary of the river Mole to form a piece of ornamental water, over a narrow neck of which the carriage road passes. Near this point is a pumping apparatus, worked by a water-wheel, which throws up a supply of water from a well to the house and offices, as well as to a fountain and several hydrants near the house.

The new planting that has been done consists of a mixture of the best evergreen and deciduous trees and shrubs, but we are sorry to see that the pretty terrace near the house has been disfigured by the introduction of incongruous trees, &c., which formed no part of the original design, and which destroy that free and open effect which it is so important should be maintained. Hartsfield is the residence of Captain and Mrs. Moir.

A LADY once consulted Dr. Johnson on the degree of turpitude to be attached to her son's robbing an orchard. "Madame," said Johnson, "it all depends upon the weight of the boy. I remember my school-fellow, Davie Garrick—who was always a little fellow—robbing a dozen of orchards with impunity; but the very first time I climbed up an apple-tree—for I was always a heavy boy—the bough broke with me, and it was called a judgment. I suppose that is why Justice is represented with a pair of scales."

PLAN OF HARTSFIELD, NEAR BETCHWORTH, SURREY.

BIRMINGHAM HORTICULTURAL CONGRESS.

PROFESSOR DYER'S ADDRESS.

VARIATION.

How important it would be to thoroughly comprehend the principles of Variation. Yet of the numerous persons who raise new varieties of plants, there are few who record anything of their experiences. Some, no doubt, have acquired a kind of intuitive tact in working with plants. Still, anything like systematised knowledge in the matter is still to a great extent a want to be supplied. Mr. Darwin has groned together in a most admirable way the facts, in many cases very scanty, which he had been able to collect before writing his book. On many of these subjects it would be very desirable to obtain the fruits of more ample experience. A more extended study of bud variation is also a matter which I would commend to your notice. Mr. Darwin arrived at the conclusion that bud variations, when they occurred at all, usually assumed at once a decided and permanent character. At the same time he thought that this might possibly be a delusion from slight varieties being overlooked. The attention which is now paid to variegated pelargoniums seems to offer an opportunity of seeing whether this conclusion is really true. Again, from time to time various curious facts have been recorded with respect to the direct influence of the pollen, not on the seed alone, but also on the female parent. Mr. Anderson-Henry has stated that the flowers of a pale *Calceolaria* became stained after the application to the flowers of the pollen of a coloured kind. Maximowicz has described a change in the shape of the capsule of a lily in the direction of that belonging to the pollen parent. Again, the flavour of melons has, I believe, been stated to be deteriorated if the pollen of some other kind has got access to the flowers producing them. None of these cases are completely free from ambiguity, and the whole matter might easily be tested by those who occupy themselves much with artificial fertilisation. The instances would certainly be rare, but if they could be established free from all reasonable doubt it would be a matter of very great interest. The difficulty lies in the possibility of the supposed influence of the pollen being really due to a bud-variation. If, however, the same kind of variation were to follow in the same plant the application of foreign pollen more than once it would be almost certain that this was the cause. For example if it could be established that the flavour of a melon was perceptibly influenced by setting it with pollen of a different kind, the thing would be established beyond a doubt. We know that *a priori* it is not improbable, since analogous cases occur amongst animals.

PLANT NOMENCLATURE.

The nomenclature of plants is a subject upon which it is becoming more and more necessary to have some common understanding between botanists and horticulturists. At the last meeting of the Floral Committee a plant was submitted to it with the name of *Lilium bulbiferum Thunbergianum aureum nigro-maculatum*. As lilies are now favourite objects of culture, this name is quite likely to receive further distinctive additions. Now it seems to me that for trade purposes such a name must be almost a deterrent to purchasers. People grumble often at a plant having two Latin names; they will grumble still more at its possessing half-a-dozen. The remedy, I think, lies in adopting De Candolle's suggestion—that we should restrict Latin names to species and varieties occurring spontaneously in nature, and should give to forms which develop under our eyes in gardens names in a modern language. This expedient would tell us in a moment whether any particular plant was or was not of garden origin, and from the language the name would also inform us whether it was raised by English, French, or German horticulturists. Still, certain modifications of botanical nomenclature must, I think, be tolerated in horticulture. In the first place, reliance has often to be placed upon distinctions which, in a botanist's eyes, seem of little importance. It cannot be objected very much, therefore, if very well marked varieties or sub-species are treated as if they were species for purposes of garden nomenclature. If there is some tangible character by which they can be distinguished from their allies, it is easy to ascertain by reference to books the rank that botanists give them. If it is often necessary, as more is known about the plants which grow upon the earth's surface, to change generic and specific names. There is usually a good reason to be assigned for doing this, but it is undoubtedly a grave source of inconvenience. Botanists will not therefore blame horticulturists if they keep to many of the old names of which it is generally easy to determine the most recently recognised equivalent. *Odontoglossum crispum* is the original and lawful name of *O. Alexandræ*, but it is not now likely to supplant the name most in use. When plants have been placed, however, from the first in genera which are obviously wrong, I think an effort should be made to give them their proper position. Having made the concessions above mentioned, I feel that it is an absolute duty to protest against plants avowedly of garden origin,

having, under any circumstances, names given to them which are of the same form as those which are given to species spontaneously occurring in nature. The case of hybrids is an exception, but the name given to these ought always, I think, to be of such a kind that both the hybrid origin and the parentage is indicated by it.

METEOROLOGY.

There is one branch of science intimately connected with horticulture in which we are far from reaping at present the practical benefit of knowledge. This is meteorology. It is too much, I am afraid, to hope that we shall ever possess the slightest control over the asperities of weather, but it is scarcely too much to look forward to improved methods of foretelling what is in store for us, as well as improved methods of obviating its effects. The study of careful records of daily observations will, no doubt, eventually reveal not only some of the causes that influence weather itself, but will also throw light upon changes in public health with which it cannot be doubted that weather is closely bound up. Such records the Royal Horticultural Society kept at its Chiswick Garden for forty-four years, and the results of the observations have been lately printed by Mr. Glaisher at the Society's expense. The practical information which can be deduced from this volume is not, perhaps, considerable; it is, however, a contribution to the accumulated stock of records which will one day find their utilization. The mean temperatures at Chiswick, as deduced from the whole observations of forty-four years, starts from its lowest point of 35°.8 on January 6th, and rises more or less gradually to its highest, 64°.4, on July 17th. If climate would only pursue this even course with some approach to constancy, vegetation would follow it with clockwork regularity. We know, however, to our cost, that it does not do so, and very considerable deviations take place to one side or the other of the mean temperature. Both are injurious. A premature development of vegetation lays it open to subsequent injury, and comes to much the same thing, as regards its effects, as a late frost. What the horticulturist really has to fight, then, are the effects of cold. The precise mode in which plants are effected by it are hardly completely known. In many cases, no doubt, the vital properties of the protoplasm contained within the cells receive an injury from the direct effect of low temperature from which there is no recovery. In other instances death is not the inevitable result even from freezing; but, as is well known, if thawing be gradually effected, no great harm will be done. Some curious experiments published by Becquerel appear to show that cold below the freezing point, like the temperature of boiling water or the electric discharge, produces an alteration in the cell walls, which render them more pervious to fluids, and therefore no longer capable of retaining their cell contents.

PROTECTION AND RADIATION.

It appears to me that the pyramid fruit trees and espaliers, which are now so much grown, are peculiarly exposed to the effects of frost, as they are pruned so that each branch overhangs, and consequently protects any below it to the least possible extent. There ought, nevertheless, to be some cheap and effective way of protecting temporarily trees of this small size from frost. Any means of anticipating it would, in view of any expedients of this kind, be of the greatest value. It may be well, therefore, to mention that in spring a dry state of air, indicated by any very considerable difference in the readings of the dry and wet bulb thermometers, is likely to be followed by frost. The reason is simple; the night frosts, which injure vegetation, arise in the main from the loss of heat from the earth's surface by radiation. If there is much moisture present in the air this loss of heat is impeded. The luminous heat radiated from the sun passes through atmospheric moisture with little impediment, but the obscure or non-luminous form in which the earth radiates it back again is caught by it, as it were, in a trap. On May 17th, at Blackheath, near London, the air was nearly saturated with moisture, the degree of humidity being represented by 94° (as deduced from Glaisher's "Hygrometrical Tables;" Saturation 100°), and the lowest temperature of the air by 44°. Both temperature and humidity fell, *pari passu*, till May 20th, when the first stood at 32.6, and the other at 69. It would be of the more importance to have warnings of the probable occurrence of low temperature, because Mr. Glaisher has shown from the Chiswick observations that periods of deficiency of temperature below the mean are often prolonged to as much as a fortnight. In the forty-four years there were eighty such. I feel strong hopes that the telegraphic communication about the weather, which the Meteorological Office now collects from stations in the British Isles and Western Europe, will eventually lead to warnings of probable falls of temperature being obtained. The apparently paradoxical fact that the temperature often falls lower, and plants correspondingly suffer more, in low grounds than in those which are adjacent and higher, has often been observed, and is well worth

bearing in mind as a practical point in laying-out grounds. I am informed that the explanation is to be found in the downward gravitation of colder air, and its consequent collection in low-lying places and hollows.

BLUE LIGHT.

In every department of scientific work it from time to time happens that announcements are made which take completely by surprise those who know what has really been made out by legitimate investigation in the subjects they bear upon. Nevertheless, the outside world always takes them up with more or less of un-critical faith. A paper published during last year by General Pleasonton, "On the Influence of the Blue Colour of the Sky in Developing Animal and Vegetable Life," appears to me to have received a great deal more attention than its utter absence of any genuine scientific character deserves. Subsequently presented to the French Academy, it has been the subject of an article by Duchartre in the *Bull. de la Soc. Cent. d'Hort. de France*. This writer points out some of the mistaken scientific views held by General Pleasonton, but though apparently inclined to reject the whole narrative as a hoax, thinks that it is vouched for by testimony too respectable not to require some explanation. For my own part, having carefully read the original paper, I do not believe, for reasons I have elsewhere stated, that blue or violet light had anything to do with the extraordinary growth of the vines, supposing that really to have taken place as described. I am slow indeed to comprehend how such a physical condition as exposure to blue light can be equally beneficial to the growth of vines, the rearing of poultry, and the invigoration of the constitution of invalids. The erroneousness of the facts argued from the absence of all knowledge of modern publications in vegetable physiology, and the wildly crochety theories, such as electricity having produced the giant trees of California, disincline me, I must confess, to attach any serious weight to either General Pleasonton's views or his result.

GARDEN VEGETATION IN SOUTH DEVON.

We have just received from Mr. Luscombe, of Combe Royal, South Devon, a collection of fresh specimens of plants and fruits from his garden, which look as if they had been culled in some favourite nook in the tropics. They were, however, grown in the open air at Combe Royal, and instead of looking any the worse for it or for this inclement season, they are in several instances more robust than we have ever seen the same plants in glasshouses. This is particularly true of the fruit of some Citrons and Shaddocks, as well as of their foliage. These, together with the more remarkable specimens in the following list, may now be seen in our Office window. They well illustrate the great advantages of adapting our system of gardening to the peculiarities of local climate, and elicit the important fact that some spots in the south of England are as favourable for vegetation as Italy or California. It is almost needless to add that the Citrus tribe receives protection, but only that of reed or wooden frames, no artificial heat or glass being used. The screens are generally removed by day in the winter, and on or about the 1st of May, are taken away entirely until November. The summer shoots of the Shaddock and Citron are magnificent.

Among other things sent, are:—*Eucalyptus montana*, a large Tasmanian tree, only once slightly injured by an unusually severe frost; *Embothrium coccineum*, a small tree which flowers annually; *Philippodendron regium*, a tree from New Zealand; *Cantua dependens*, this is sometimes injured; in another garden, about a mile off, this once flowered magnificently, and was awarded a certificate of merit for the blossoms; *Olea illicifolia*; *Myrtus* (*Eugenia*) *apiculata*; *Abutilon vitifolium*; *Berberis Fortunei*; *Berberis nepaulensis*; *Ilex latifolia*; *Benthamia fragifera*; *Desfontainea spinosa*; *Arundinaria falcata*, nearly thirty feet high; *Aralia japonica*; *Dimorphanthus mandshuricus*; *Acacia dealbata*, the parent plant, destroyed by the weight of snow about twelve years ago, was about fifty feet high; *Camellias*; *Gunnera scabra*, leaf and fruit, the former is a small specimen, as the first leaves were destroyed by an April frost; *Bambusa Metake* (Japan); leaf and flower stems of *Chusan Palm*; *Rhododendron Fortunei* (China); *R. Thomsoni*, a splendid Sikkim species, which flowers annually; *R. blandfordiæ* *florum*, a wonderful yellow and orange Sikkim species, very free-flowering; *R. arboreum*, the true species, raised from Indian seeds by the late Mr. James Veitch; many plants were destroyed by frost two or three years since, two stems being quite three feet in circumference; *R. cinnamomeum* (India); *R. nobile* (Ceylon); *Azalea indica Fortunei*; *Seville oranges* from a tree known to be nearly, if not quite, two hundred and fifty years old; summer shoots of Citron; summer shoots of Shaddock; Lime (Citrus) and shoots; fruit of Lemon, *Seville orange*, Citron, and Shaddock; *Amaryllis* blooms and leaves, raised from seed, and bloomed in the open air unprotected, in a garden a mile distant from Combe Royal.

NOTES OF THE WEEK.

— THE potato disease is said to be making its appearance not only in the west of England, but in other parts of the country.

— IN Portugal the weather is reported to be excessively hot, and we hear that the vine disease is spreading.

— WE are glad to report that, notwithstanding the peculiar severity of the early summer, the distinct and graceful *Amarantus salicifolius* is thriving well in the gardens round London.

— IN the pretty town of Brookline, State of Massachusetts, a gentleman has been arrested and fined for nailing up a vine on his house on Sunday. There is quite a row in hitherto peaceful Brookline, in consequence.

— *DIANTHUS RAMOSUS*, a pretty and distinct species of pink, is now in flower at the Royal Gardens, Kew. It forms a dense, much-branched tuft, about eight inches high, and produces an abundance of purplish rose-coloured flowers.

— A REMARKABLY beautiful *Nierembergia* (*grandiflora*) is now in flower in Messrs. Veitch's nursery at Chelsea. In habit it resembles *N. frutescens*, but has much larger flowers; and as these are produced in great abundance, the effect is all that could be desired.

— THE great injury done to vegetation during the recent eruption of Mount Vesuvius has been attributed not so much to the heat of the ashes scorching it, or to the dust closing the pores of the leaves, as to the destructive action of the large quantity of chloride of sodium (common salt) which fell with the ashes.

— MR. J. A. FULTON, of Delaware, writing to an American paper, says that there are now in that State about 5,000,000 peach trees, planted on 40,000 acres of land. Last year the shipments by rail and water amounted to about 3,000,000 baskets. The annual net value of the products of the present orchards in future is placed at 1,830,000 dollars. No increase of production is recommended.

— THE strike among the London market-garden labourers still continues. The old market-garden hands have found employment at haymaking, harvesting, and similar work; and their places are filled by strange hands and also by boys, who, under the superintendence of foremen, do the fruit-picking and the roughest of the weeding.

— MANY of our readers would probably be interested in seeing the extraordinary specimens of shaddocks, citrons, oranges, &c., grown at Combe Royal, in Devon, and now exposed to view in the window of THE GARDEN Office. We have never witnessed such vigour of shoot and foliage on plants grown in the open air in countries much warmer than ours.

— A PARTY of invalids, in number about seventy, residing at the Royal Hospital for Incurables, Patney Heath, were entertained a day or two since at a garden party in the beautiful grounds at Rotherhampton belonging to Baron and Baroness Hambro. The baroness and several willing ladies did everything in their power to promote the comfort of their invalid friends. The conveyance of them from and to the hospital was admirably managed.

— A VERY good suggestion was made the other evening with regard to the Serpentine. Sir John Troloway proposed that bathing places of an ornamental character should be erected in the centre of the lake. From the banks they would present the appearance of islands, while they might be of such a size as to secure a large space inside for swimming. A great opportunity for diversifying and otherwise beautifying the Serpentine was lost when it was cleaned out a short time ago. The banks were left even uglier and more formal than they were before.

— THE latest particulars received regarding the thunderstorm on Tuesday night show that it was unusually severe and destructive. All the market-gardeners and fruit-growers who attended Farringdon Market on Wednesday morning, gave a deplorable account of the damage done to their property. In many cases acres of ground, covered with strawberry plants and raspberry canes, were, at the time the owners left, at least eighteen inches under water; and the ripe fruit, which would have been gathered during the next six hours, has of course been spoiled, and numerous female pickers have in consequence been thrown out of their usual summer employment. The crops of French beans and scarlets have been buried in the soft ground by the force of the rain; and trees have been stripped of plums, cherries, and other stone fruit, by the strength of the lightning and heavy downfall of rain. A man named Ellison, in the employ of a market gardener and potato merchant in Covent Garden Market, while passing along James Street, Long Acre, was struck by the lightning across his face and was instantly deprived of sight. At Edmonton and Enfield, all pedestrian traffic was stopped owing to the vast accumulation of water, which covered whole fields of ripe corn, and also laid down and spoiled large tracts of vegetable and fruit ground.

— WE hear that a Bill has been presented to the National Assembly by M. Joigneaux, the purport of which is to convert the kitchen gardens of Versailles into a practical school of horticulture, and this project has every chance of success.

— THERE is now to be seen in the conservatory of the Royal Horticultural Society, at South Kensington, a pair of American aloes in bloom, and probably such a match as is seldom seen. They are in every way alike, and have thrown up their noble candelabra-like flower stems to a great height.

— A PLANT bearing the name of *Scabiosa parnassiae* is now in bloom in the herbaceous ground at Kew. It forms a neat spreading tuft not more than four inches high, and produces pretty flesh-coloured flowers, which are about an inch and a half in diameter, in great abundance. This is the best species of the genus we have seen, and will doubtless soon find a place in all good collections.

— THE head constable of Liverpool desires to remind gentlemen living in the suburbs of that town, that about this time last year several robberies of grapes took place. He hopes, therefore, that gentlemen having vineyards will see the necessity of taking more than ordinary precautions to prevent, as far as possible, a repetition of those occurrences.

— THE fine weeping willows in the gardens of the Holme, Regent's Park, are perishing from the attacks of carpenter caterpillars which bore through them in all directions, soon killing the trees. Their attacks are so vigorous, that there is quite a heap of sawdust at the base of each specimen. We hope soon to illustrate these creatures and their ravages in our department of THE GARDEN devoted to "Garden Destroyers."

— A CORRESPONDENT informs us that he saw the other day in the Botanic Gardens, Belfast, a magnificent specimen of *Orchis foliosa*, a terrestrial Madeira species, well deserving of more attention than it usually receives. It quite filled an eighteen-inch pan, from which it threw up between thirty and forty fine spikes of charming rosy purple flowers. It grows about a foot and a half high, and is a plant which, when in bloom, is sure to elicit general admiration.

— NOTWITHSTANDING the very fickle season which we have experienced, many of the sub-tropical plants at Battersea Park are making good growth, and the sub-tropical garden generally is looking well. Lovers of gardening visiting London, and having a few hours to spare, cannot spend them better than in paying a visit to this park, where they will find much to interest them, both in the sub-tropical garden, and in the bedding arrangements generally.

— THE handsome and neatly-habited *Ononis fruticosa* is now in flower. It is seldom seen about London, though no doubt it was often planted in days gone by; but being a dwarf mountain shrub, it probably often perished from being associated with coarse subjects in plantations. It is suitable for grouping with the dwarf American plants, for banks, for rockeries, or for planting alone on turf.

— THE most beautiful objects in the suburban gardens of London now are the round-headed Acacias (*Robinia pseud-acacia inermis*). Their deep fresh verdure is delightful to look upon in the heat of summer; but, unhappily, those who have the good taste to plant them are few. The early-withering lime is planted in nearly every garden, and annually mutilated in the vain hope of compelling it to assume the compact proportions which this Acacia assumes of its own nature.

— THE white *Lapageria* is now a beautiful ornament in the conservatory at the Holme, Regent's Park. It is trained first on a trellis against the wall, and then across the house on a strong cord, about four feet from the roof and ten feet from the ground, the shoots being allowed to hang gracefully down. On the opposite side is a plant of the old, or crimson kind, which meets and mingles with the shoots of the white one. The effect of the mixture of the variously-coloured flowers is, as may readily be supposed, very charming. Their beauty is not fully seen when the plants are trained stiffly against walls or trellises. The shoots should be allowed to hang freely down.

Stung to Death by a Bee.—An inquest was held the other day at Twickenham on the body of Miss Elizabeth Hough, an aged maiden lady. It appears that on Friday morning, the 19th instant, the deceased was in her garden, inspecting the beehives, when she suddenly called out, "Oh, gardener, I've been stung; come and help me!" The gardener found only one bee in her hair, which he removed. Deceased soon afterwards became unconscious, and a medical man was sent for; but when he arrived the lady had been dead a quarter of an hour. He made a *post-mortem* examination of the body, and found a great deal of discoloration behind the ear, caused by the sting of a bee. Major Lewis Hough said the deceased,

who was his sister, was of a delicate and nervous constitution. In the autumn of 1870 she was stung by a bee, and on that occasion it produced very peculiar consequences. She lost consciousness, and remained in that state for two hours. The coroner remarked that some persons were peculiarly susceptible, and in such cases, when syncope set in, the best remedy was a little brandy or ammonia.

Alexandra Park.—At a public meeting held at the Mansion House the other evening, under the presidency of the Lord Mayor, the following resolution in reference to this park was proposed:—"That this meeting having had placed before it a prospectus for the utilization of Alexandra Park and Palace in the true interests, moral as well as physical, of the people, pledges itself to every legitimate effort to secure and complete the success of the enterprise." Lord Lyttelton seconded the motion, and expressed his hearty approval of the great object which the meeting was assembled to promote, namely, to establish a Crystal Palace for the North of London. The resolution was unanimously carried, as was also another to the effect that the plan suggested in the prospectus, of enabling the people to become themselves the purchasers of the park and the palace, deserved the greatest encouragement.

Proposal to Open a London Square to the Public.—The experiment of an open garden for the public, says the *Pall Mall Gazette*, is about to be tried by Lord Westminster, who proposes to lay out and plant the space now enclosed in Ebury Square, and to remove the railings. If the arrangement proves a success other squares will, no doubt, in due time, be also thrown open, and a new feature of a pleasant description be introduced into the aspect of London. Ebury Square is in all respects a fit subject for an experiment of this nature. It has for some time shown a tendency to follow the downward path of Leicester Square, and has been allowed to fall into such a state as to become an eyesore to the neighbourhood. There are also numbers of poor children in the district to whom an unenclosed square will be an inestimable blessing. Ebury Square was originally lammas land. It formed part of Eybery Farm, leased by Queen Elizabeth to a certain Mr. Whaske for £20 per annum, who, according to Strype, sublet it to "divers persons, who, for their private commodity, did enclose the same, and had made pastures of arable land, thereby not only annoying her Majesty in her walks and passages, but to the hindrance of her game, and great injury to the common, which at Lammas was wont to be laid open." Ebury Square is therefore not without some experience of the "many-headed" public, and will perhaps not be sorry to renew its acquaintance with its old friends. It is, however, to be hoped that the square will not be appropriated by agitators for political purposes. Whatever may be the flowers selected to adorn Ebury Square, the flowers of eloquence should be rigidly excluded, and under no circumstances should the "discussion of grievances" form part of the programme of its amusement.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.
PRIVATE GARDENS.

Indoor Plant Department.—Now, when large plants put out in beds and borders are making free growth, and require a good deal of water, basins are formed round their base by removing the soil to the depth of three inches or so, and of a diameter corresponding with the size of the plant. These basins are loosened in the bottom with a steel fork, taking care not to disturb any roots that may be near the surface. This loosening of the soil enables the water to penetrate to the bottom of the beds. Zonal Pelargoniums for conservatory decoration are being repotted, and occasionally well watered with manure-water, the flowers, too, are all picked off as they appear, and the plants are shaded for a time, and are allowed plenty of air. Cockscombs, to succeed those already in bloom, are shifted into their flowering pots, and any likely to become "leggy" are cut over and re-inserted in the pot, using a little sand to induce the formation of roots. Fuchsias are pinched in, and well syringed and watered, until a short time prior to their being required for use. Japan Lilies done blooming are placed out of doors in sheltered positions, and are gradually dried off, after which they are laid on their sides, to protect them from the heavy rains. Heaths in pots are set out of doors, also many other hard-wooded plants and succulents. Chinese Primulas are introduced into gentle heat in order to invigorate them a little before cutting off all their shoots, which will then be treated as cuttings to form plants for next season's blooming. Calceolarias for next year's work are being pricked off into boxes, using as soil good yellow loam, a little leaf mould, some well-decayed manure, and a little silver sand, all finely sifted for the surface of the box,

the rougher material being placed in the bottom. A late sowing is also being made. In sowing, the seeds are scattered equally and rather thinly on the surface of a pan of light soil, and barely covered. The pan is then placed in an almost spent hot-bed, usually one used for spring propagating, and on the surface of the pan a pane of glass is placed, which is covered with some damp moss, or instead of placing the moss on the glass, some litter, or other similar shading material, is placed on the glass of the frame. No sun is allowed to reach them before they germinate, for it is necessary to prevent the soil from becoming dry, and, even after the young plants do come up, the shading is retained on the frames. A little air is always kept on, except for a night or two after they have been potted or pricked off. Begonias intended for winter blooming are being cut back, with the exception of such kinds as *manicata*, *Roi Leopold*, &c.; *B. nitida* is one of the best among flowering kinds, but it never produces such fine blooms when confined in a small pot, and kept cut down, as it does when allowed to ramble at freedom in a stove or Orchid-house. If the roots find access to a bed of good soil, mixed with chips of sandstone, brickbats, &c., and the stem is trained up to the roof, it produces magnificent trusses of bloom.

Flower Garden and Shrubbery.—In shrubberies, unsightly branches and those intruding on walks, are removed. Conifers, in some cases, are also being shortened in a little. Rose-budding is being proceeded with; from the stocks the roughest of the shoots are removed, but those to be operated on are preserved untouched, unless they are long and much branched. Pelargonium cuttings are now being taken off, and inserted in wall borders; but Verbenas are commonly struck in frames. Dahlias, as they advance, are fastened to stakes, taking care not to tie them up too closely or stiffly. Holly-hocks have their tops pinched off when they get about six feet high, and are encouraged to produce good flowers by applications of manure water. Tufts of Pampas Grass thorough waterings are given, as even heavy rains sometimes fail to reach the roots.

Indoor Fruit Department.—Pines are now producing, as a rule, suckers freely; but where they refuse to do so, as soon as the fruit is removed, they receive plenty of water, additional heat, and atmospheric moisture—conditions which soon cause them to produce good and strong suckers. Young pot Vines are now allowed a little more air and a drier atmosphere, but no decrease of water at the root is yet permitted, as the aim is to preserve the foliage in as good and healthy a state as possible. Melon beds, in which the plants have borne fruit, are being partly renewed, the sashes and glass washed, and young healthy Melons planted, the growth of which is encouraged by a good bottom heat, and a high moist temperature. From Cucumbers in frames all decaying leaves are removed, also male flowers and superfluous wood. Gano and other kinds of manure water are freely administered to old plants. In orchard-houses, where the fruit is ripening, a steady warm temperature is maintained; and, in order to impart increased flavour, a little air is kept on night and day. Pot plants, having yielded their crop, are placed outside, so as to get their wood better ripened.

Hardy Fruit Garden.—The shoots of fruit trees on walls continue to be thinned and laid in. Peach and Nectarine trees have the fruit-bearing wood shortened in a few inches. Laterals are removed, but not quite close to the main shoot. Newly planted trees require little pruning, it being considered better practice to remove the shoots in a young state with the finger and thumb. Stone fruits are being budded, some of them, on stocks, cut as low as the surface of the ground, and others considerably higher. The syringe is used freely amongst wall trees, and choice young standard Pears, to remove insects. Moss, if any, on valuable fruit trees or bushes, is scrubbed off with a rough brush, and the parts on which it has been growing are washed with brine, not too strong.

Kitchen Garden.—As Potato ground becomes empty it is filled with Broccoli, Scotch Kale, or other greens. For Broccoli a western aspect is preferred; but Scotch Kale and Brussels Sprouts, it need scarcely be stated, will succeed in the most exposed situations. In cases in which stubby Cabbage stumps have been left they are producing a second crop. To encourage this the soil is dressed with well-decayed manure, and loosened with a steel fork; only two, or at most three, offsets are allowed to spring from each crown. A small sowing of some dwarf early kind is made, so that a few nice little heads may be produced to succeed the Coleworts. All Potato Onions are being lifted and dried; spring-sown ones are making good progress. A few radishes are still sown in cool places, and a few more Lettuces are planted out. Some Onions are also sown for salading; some out of doors, and some in frames, where they can be protected from heavy rains. Scarlet Runners are pinched to induce them to throw out laterals, and thus continue in bearing; the removal of all pods just as they are fit for use, whether required or not, considerably prolongs the bearing season. Tall Peas

are being pinched, and where time can be spared, a good soaking of manure water now and then is given them.

NURSERIES.

Indoor Department.—Camellias that have made good growth have their young shoots hardened by gradually exposing them to more air. Young Azaleas are being stopped for the last time; some of them are being tied down very near to the surface of the pots, so as to induce a stubby habit. Young plants of Clerodendrons, of the *Balfourianum* or *villosum* section, are being potted on, using for the purpose a good rich compost. Cuttings of climbing Ficuses, such as *F. barbata* and *repens*, besides being planted in sandy soil in frames in the propagating pit to root, are cut into pieces from six to eight inches long, and potted at once into a compost of two parts of peat and one of sand. *Philodendron Lindenii* is cut up into pieces about a foot or more in length, and potted into a compost of rough peat, crocks, and sphagnum, finishing with a layer on the top of pure sphagnum. The shoots are then pegged down to the surface, and after a short time, by the assistance of a little heat and the moist moss, they emit roots from every joint. Gloxinias are being increased by means of well-ripened, sound leaves placed in pots of sandy peat surfaced with silver sand. The pots are then plunged in a gentle bottom heat under a bell-glass or hand-light in the propagating pit. Young Palms are being potted off from seed-pans into sixty-sized pots, using a compost of rotten dung, loam, peat, and sand. *Cissus discolor* and *amazonica* are being increased by means of cuttings consisting of two joints, one being under the soil and one just above the surface. Well-ripened wood is required for this purpose, otherwise they will be sure to damp off. Some kinds of succulents are being repotted in a compost consisting of good yellow loam, well-decayed manure, some broken crocks, and a little sand. Some of the finer kinds of Selaginellas are being increased by means of good healthy pieces having roots attached to them being taken off and potted into small pots, the soil used being peat, leaf-mould, broken crocks, and silver sand. Ferns from spores have the surface soil of the pots or pans in which they are grown cut into small pieces, which are carefully lifted out and placed on the surface of freshly filled pots. A few of the younger Ferns are being repotted, using for the purpose sandy peat and a little sand; sometimes a little loam or leaf-mould is added. Young plants of *Platyserium aleicorne* are also being potted; for these the compost is of a rougher character than that for most other ferns, being rough turfy peat, loam, broken crocks, and sphagnum. Some Orchids are being top-dressed, an operation which should, however, have been performed much earlier in the season.

Outdoor Department.—Cultivators are at present engaged in lifting ripe bulbs, such as those of Crocuses, Narcissi, Ixias, Sparaxis, Ornithogalums, &c. Pansies are being lifted and divided into as many parts as there are shoots springing from the base. They are set out in beds about four feet wide, the lines being six inches apart, and the cuttings an inch or so asunder. Temporary frames or hoops are placed over them covered with mats, which are removed as soon as they begin to root. More care is taken with the finer kinds of Pansies, but some that have just been treated the same way as the bedding ones are looking quite as well. Carnations are being prepared for layering by removing all lateral shoots and flower-spikes. Some herbaceous and alpine plants are top-dressed; those making vigorous growth are shifted at once into larger pots, in order that they may fill them with roots before the days turn cold; others are being shifted from thumb pots to sixty-sized ones. If the plants are valuable, a little bottom heat is also applied. In potting, the rarer kinds are divided into as many pieces as will make nice little plants, and they are potted individually into thumb pots. For most of the kinds, a suitable compost is two-parts good loam, one of leaf mould, and a good admixture of sharp sand. Young shoots of sweet Rockets, and other herbaceous plants that have been pegged down throughout the summer, are also used as cuttings. Rose-budding is being proceeded with. Points of Conifer shoots, bearing signs of the presence of the pine-beetle, are removed and burned; care, however, is taken to cut these shoots off as far as the beetle has bored, otherwise the amputation will have been made in vain. The wood of young fruit trees is being thinned and trained into form.

MARKET GARDENS.

In dry weather, Celery, Vegetable Marrows, and other crops are liberally supplied with water. In districts where the supply of water is deficient, French Beans, Cauliflower, Broccoli, Lettuces, &c., are grown as summer crops, in preference to Vegetable Marrows and Celery, which require too much water to repay the trouble of supplying it. Cucumbers are allowed to occupy frames in summer; the frames will, however, be cleared of them by-and-bye, the beds will be renewed, and Cauliflowers and Lettuces will be sown therein for the earliest planting next spring. At present a few

Lettuces are being planted in open spaces formed by the removal of the present crops. Celery ridges for the main late crops are formed, some with four feet spaces between them, and others with eight feet spaces; the narrow beds are planted with two lines of Coleworts or Cos Lettuces, and the broad ones with four lines of Endive. Fruit gathering forms the greatest part of the current work; as soon as gathered, it is placed in little round vegetable baskets, covered over with a few Rhubarb or other leaves, made pliable by having been cut a day or two previously, and fastened down by crossing pieces of stout willows. Potatoes are brought to market in the same way; some separate the larger from the smaller ones, either with the hand, or through large-sized wire sieves. Tomatoes sufficiently advanced, and whose fruit is fast swelling, have the points of the main shoots cut off, so as to throw additional vigour into the fruit; laterals are carefully removed from all advancing crops showing flower, retaining only such as are producing good clusters, at the same time avoiding too much wood. They are well watered at the root, and a little manure water is found to be very beneficial. Asparagus is allowed to grow freely, removing only the small sprays about the base; the beds are kept clean by hand-weeding, which, in many cases is performed by boys. These youths are employed for this and similar purposes in place of the regular hands that are out on strike. Seeding crops now receive great attention in the way of tying up the plants, watering, &c., most of them, such as Onions, Leeks, Lettuces, Cauliflowers, &c., being in full bloom, and beginning to form their seed. Cabbage seeding plants are being cut over as the seed becomes ripe; stalks, seed-pods, and all, are laid out on canvas to dry, or hung up in bundles in dry sheds. Pot herbs are being cut over when ready, and tied into little bundles for drying for winter use. A young stock, however, is always preserved by late sowings, and second growths, from early cut plants.

HINTS FOR AMATEURS.

Flower Garden.—See that Roses are clean, and kept in a healthy growing condition. To insure good autumnal bloom, cut back the shoots to three or four eyes as soon as the first blooms are over, and soak the roots with manure-water. Finish budding Roses by simply making a slit as near the base of the shoot as possible, insert the bud, and tie with cotton, or woollen thread is best for this purpose; very little tying is needed when the cross cut is dispensed with, as it ought to be. Help weak or late plants, such as Dahlias, Hollyhocks, &c., with manure water to fill their allotted spaces.

Fruit Garden.—Let Vines have plenty of air, night and day, as soon as the fruit begins to colour. In the case of Peach and Orchard houses, a moderate crop, perfect health, spotlessly clean houses, and airy open treatment, lay on colour and flavour. Keep Melons ripening rather dry, and cut the fruit as soon as any flavour is perceptible, or it begins to crack around the stalk, otherwise it is apt to split, and its appearance becomes ruined. Cut all fruit on Cucumbers that are fit thrice a week; stop every shoot, and remove any superannuated leaves, at least once a week. In the case of hardy fruits, mass the small ones together, so that they may be netted over to keep them from birds. For instance, plant the walls with Cherries, Gooseberries, Currants, and Raspberries, and plant the ground between with bush fruit, such as Gooseberries and Strawberries, then net from wall to wall. The nets will last much longer thus highly elevated above the ground, and the fruit-gatherer can go in at any point and gather the fruit in comfort; the birds also give up trying to reach the fruit through the nets, and thus one great source of wear and tear of nets is avoided. There is considerable art in the gathering of fruit. It should not be handled at all, or as little as possible, and no crushing or overcrowding should be indulged in. Very much of the difference between good and bad fruit at dessert results from the gathering. Vine leaves, or those of the Plane and the Sycamore, are the best for laying fruit upon. Cabbage or Cauliflower leaves are about the worst. In wet weather especially, these taint such fruits as Raspberries and Strawberries with a Cabbage flavour. Such fruits, again, as Gooseberries, Currants, and Cherries should be gathered in clean baskets, without leaves. If laid thin, their skins will protect them from injury, as they will appear in better condition than if they had been previously bedded on Cabbage or any other fine or succulent foliage. As to the time of gathering fruits the early morning is the best. Better and pleasanter far to gather dessert then, and store in the pantry or cellars till our early or late dinner, than rush out in the mid-day or afternoon sun to gather fresh fruit for dessert; that gathered in the early morning will eat by far the fresher and sweeter of the two.

Greenhouses, &c.—Shade late Pelargoniums and Fuchsias from the sun, and thus prolong their bloom. Allow climbers to grow and flower freely, and to assume for a time a free habit.

Better an empty house at this season, than one filled with faded, worn-out flowers.

Kitchen Garden.—The secret of a well-furnished garden is incessant attention to trifles. The main crops are pretty sure to be got in all right and in time, but it is the successional sowings and plantings that keep the garden full. Make some last sowings of Peas—a good marrow and a good early sort—such as First Crop; sow also Walcheren Broccoli, Lettuces, Endive, Cabbages, Horn Carrots, Turnips, and Radishes. Plant out Broccolies, Greens, Savoy, Cauliflower, Lettuces, Cabbages, and Celery, on all vacant ground. Water growing crops in dry weather, destroy weeds, and scarify all ground between such crops.

D. T. FISH.

OBITUARY.

WE have to record the death of Mr. Ramsay, late fruit-tree foreman to Messrs. James Veitch & Sons, at the age of seventy-one. For the last few years Mr. Ramsay had resided at Leicester, where he died only a week after being elected a pensioner of the Gardeners' Royal Benevolent Institution.

COVENT GARDEN MARKET.—July 26th.

Flowers consist of Cockscobs, in four and six inch pots; Balsams, in six-inch pots; Japan Lilies, finely bloomed, in four and six inch pots, including *L. speciosum*, roseum, a few of punctatum, and some nice plants of *L. auratum*. The hardier kinds of Lilies, such as *L. longiflorum*, *tigrinum*, &c., are also brought in in the form of cut flowers. Fuchsias are very abundant, and although they consist chiefly of the free-blooming old kinds, yet amongst them may be found several of the newer sorts, both single and double. Hydrangeas, both pink and blue, from spring-struck cuttings may be obtained. Sensitive plants (*Mimosa pudica*), for such as have small warm conservatories, may also be had; likewise nice plants of Achimenes and Gloxinias, both of which are great favourites. China Roses are still furnished in pots, although many handsome-leaved plants, such as Begonias, Marantas, Dracenas, Caladiums, little Palms, Ferns, and Mosses. Cut flowers principally consist of Rose blooms; Carnations, more particularly dark clove-scented ones; wild grasses, which, mingled with ordinary flowers, add considerably to their gracefulness; and blooms of the double-white Feverfew, the rose-coloured Achillea, Lupin blooms of different colours, and flowers of many hardy annuals and perennials. Strikingly beautiful are blossoms of the blue Corn-flower. Dahlia blooms are also now coming in; and likewise those of the white Water Lily (*Nymphaea alba*) which are sold at a penny a piece.

St. Swithin's Day.—The result of observations taken at Greenwich for the twenty years preceding 1861 proves that no confidence whatever is to be placed in St. Swithin's Day. Indeed, the more it rains on the 15th of July the greater the probability of fine weather. In 1841, when St. Swithin's Day was wet, there were 23 rainy days between the 15th of July and the 24th of August; in 1845, 26 rainy days; in 1851, 13 rainy days; in 1853, 18 rainy days; in 1854, 16 rainy days; and in 1856, 14 rainy days. On the other hand, when St. Swithin's Day was fine, as in the following years, the results were painful in the extreme. In 1842, 12 rainy days; in 1843, 23 rainy days; in 1844, 20 rainy days; in 1846, 21 rainy days; in 1847, 17 rainy days; in 1848, 31 rainy days; in 1849, 20 rainy days; in 1850, 17 rainy days; in 1852, 19 rainy days; in 1855, 18 rainy days; in 1857, 14 rainy days; in 1858, 14 rainy days; in 1859, 13 rainy days; and in 1860, 29 rainy days. St. Swithin, therefore, is no more to be depended on for a constant supply of water than the Metropolitan Water Companies.—*Pall Mall Gazette*.

THE GARDEN.

“This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE.”—*Shakespeare.*

THE ROSE-AMATEUR'S GUIDE.*

WITH varied feelings, kindly and pleasant all of them, we welcome another issue of this well-known and well-loved manual. First, with happy and grateful memories of the time when, nigh upon thirty years ago, we first fell in love with the Rose (and with everything else that was beautiful), and were introduced by Mr. Rivers to the Garden Queen. Ah, what sweet summers of happiness this little book—so freshly, so truthfully written from the fulness of an earnest heart—brings home to memory! How many hundreds have sat with it, beneath umbrageous branches or in some cool grot, and have learned from its genial tone and lucid teaching to appreciate more highly, and to realize more fully, the beauties of the royal rose! It has brought new brightness to many a bright English home, to castle and hall, to parsonage and cottage too, not only for the eyes, but for the hearts of those who first learned from its pages that “gardening is the purest of human pleasures,” and that the chief grace of a garden is the rose.

And then we think of “that grand old gardener,” the author, and how much thankfulness is due to him from us all, not only for what he has written, but for what he has done for the garden—not only for this “guide” to the culture of roses, and for other guides equally reliable, which he has published on the culture of fruit, but for yet more valuable *works*, as, for example, the introduction of the Manetti stock for roses, which has multiplied the enjoyment of their loveliness a thousandfold, and also the invention of orchard houses, and consequently of the profitable and enjoyable cultivation under glass of fruits, which were previously grown (and very frequently destroyed) *al fresco*.

It would, of course, be most undignified in a State or Government to recognise any merit in such a man as this; but we gardeners, nevertheless, take leave to think that Thomas Rivers has done more for the happiness of his countrymen than a great number of personages, whose names are inclosed, like sandwiches, with titles to left of them and letters to right of them; we almost dare to believe that this little red book has diffused as much pleasure and profit also as some of those huge volumes which are bound in blue; and we are quite sure that it will be remembered and read, when the scientific dissertations of haughty theorists, who never huddled a rose nor pruned a fruit tree, shall have passed, easily and greasily, from the butterman's hands into oblivion.

KEW GARDENS.

DR. HOOKER AND MR. AYRTON.

THE debate in the House of Lords the other night on this question proved a failure. Whatever might have been the reason, the subject seemed to create no interest, and the House was in that condition which might be roughly described as empty when Lord Derby rose to open the debate. Lord Derby, doubtless, did his best, and we readily admit that he deserves great credit for the firm and earnest way in which he vindicated the case of Dr. Hooker. After stating what has been already made familiar to the public, he spoke of the case of the recently discharged Curator's clerk, who won his appointment at the competitive examination last spring:—

“Unwilling,” he said, “to go more than I can help into details—but, as a sample of the way in which matters have been carried on at Kew, I must refer to a matter which occupies the first twenty-five pages of the Blue-book, a signal instance of how departments contrive to make unnecessary work for themselves. It appears that an assistant was wanted for the Curator to perform certain special duties. Those duties involved the keeping of accounts, the custody of stores, the conducting of a large correspondence, and the direction of the foremen employed in the gardens. The appointment is competed for, not by an open, but a special examination, showing that special qualifications were required, and is given,

without any reference to Dr. Hooker, to a man who had been employed in the gardens, well known to the Director, and of whom both the Director and the Curator had formed a very unfavourable opinion. Dr. Hooker's report upon him is—‘Writes indifferently, spells badly, incompetent to direct foremen in regard to stores; no preliminary education or training to fit him for the situation. He has never kept accounts, he has never been in charge of stores, and cannot conduct a correspondence creditably.’ (A laugh.) Dr. Hooker entreats that he may be removed. The Treasury concur; in a letter dated May 2nd of this year the First Commissioner objects; and on June 26th the Treasury repeat their expression of opinion in a letter which is too long to quote, but which I am bound to say, to the credit of the writer, the Lords of the Treasury, and, I suppose, principally of the Chancellor of the Exchequer, does very clearly show that they thought, in this instance, the position of the First Commissioner to be indefensible. The man was discharged at last, and then follows a controversy between the various departments concerned—Treasury, Board of Works, and Civil Service Commission—which certainly points to a very curious state of confusion and uncertainty as to the status of persons holding appointments in the Civil Service. Justice compels me to admit that in this case the Treasury rather tardily set themselves right. But the fact remains that everything in the power of the First Commissioner was done to force on Dr. Hooker a man whom he disapproved of, whom he knew to be unfit, and for whom he could find no suitable employment.”

May we ask, in the face of the man winning at the examination, if the above statements respecting his qualifications be true? Lord Derby then diverged from the contents of the Blue-book, and made a statement which seemed to us, to say the least of it, very singular, and very unjust to the person referred to.

“But, my lords,” said Lord Derby, “I fear that the list of these complaints is not fully exhausted by what appears in these papers. I hold in my hand a statement coming from what ought to be the best authority, to the following effect:—That within the last ten days the First Commissioner has sent to Dr. Hooker two letters containing vague charges of jobbery and mismanagement; one from a late foreman of Kew, who is subject to hallucinations, and who, after engaging himself to another place, without informing the Director, suddenly left, wholly of his own accord, bringing purely imaginative charges against the Curator. For these the man abjectly apologised, and wrote to the Director expressing his regret, and begging that he might be taken into favour again. This man is known to have been for some time in communication with Mr. Ayrton, who, at the last hour, brings him forward.”

This person was, however, not brought forward by Mr. Ayrton in the Blue-book, and had no means of defending himself from a false and ridiculous charge.

The Duke of St. Albans followed in defence of Mr. Ayrton, and showed, by the following letter from Sir Benjamin Hall to Sir W. Hooker, that at least one other Chief Commissioner had felt it his duty to interfere at Kew:—

“I think it necessary again to call your attention to the present state of the gardens at Kew, which I do not consider at all satisfactory. Soon after I became First Commissioner I visited the gardens and pointed out to you the very bad condition of the walks, the coarse appearance of the grass, and the very insufficient supply of flowers for the beds. Hardly any preparation had been made for filling the beds this year by providing cuttings; and when I desired to have a few more flower beds, in order that the gardens might look more gay in the vicinity of the Palm-house, I was told there were not cuttings enough to plant out, upon which I directed that the new beds should be filled with annuals. In short, there was little, scarcely any, preparation made; and when I was at the gardens a few days ago I was informed that very little had been done in the way of making provision for next summer. I also saw that the walks were in a very bad state; the day was wet, and I was thus better able to judge of their condition than if it had been fine, for I could see the hollows in which the water stood most clearly. You agreed with me in the observations I made, and you quite acquiesced in the opinion I expressed, that the condition of the gardens was not at all what it ought to be. . . . The funds provided by Parliament are enormous, and ample for the purpose; and when I compare the state and general appearance of the Botanic Gardens at Edinburgh with those at Kew, and look at the miserable sum of £1,000 which is expended on the Edinburgh Gardens, which sum covers all salaries and expenses of every kind, I am sorry to say that the deductions to be drawn are by no means in favour of Kew. Instead of your having a very insufficient supply of flowers to plant out in the gardens of Kew, those gardens should afford ample supply for other places; and it is very probable that I shall require geraniums and other half-hardy plants to put out in some of the clumps in St. James's Park and Kensington Gardens next year; I must therefore request that you will have ample provision. I wish also that the walks may be put in better order, and the grass kept in a better state, and that you should plant a large number of laburnums, lilacs, and other flowering shrubs in those parts of the gardens and pleasure grounds where they can be placed with advantage.”

Lord Stanley of Alderley ventured to think that the noble earl would not meet with much gratitude from the country for having added this Blue-book to the already too large number which existed, nor from their lordships individually, for having imposed on them the burden of such tedious reading. He disagreed entirely from those who accused Mr. Ayrton of making himself unpopular. From

* “The Rose-Amateur's Guide.” By Thomas Rivers. Longman & Co. 1872.

the nature of things, it was not the man but the office that was unpopular. The Board of Works had to supervise and curtail the expenditure of public money, and if such supervision was carried out with fidelity to the public interests, it must be unpopular among those who are supervised. The necessity for the noble earl's motion had been created by the memorial signed by eleven men of science and addressed to the Prime Minister. He did not attach any weight whatever to some of the signatures of that memorial, among other reasons because it had been called forth, not by sympathy for Dr. Hooker, nor by ill-will to Mr. Ayrton, but by the fact that Professor Owen, of the British Museum, had expressed the views contained in Appendix No. 3 of the Blue-book, that he had severely criticised Dr. Hooker and the Kew Herbarium, and had expressed the desire for its removal to a central botanical museum in London. Besides the scientific hostility to Professor Owen, there existed among some of the partisans of Dr. Hooker hostility to Professor Owen on other grounds, for the discussion of which their lordships' House was not a very fitting place. Dr. Hooker applied to Lord Clarendon to be sent to a Botanical Congress at St. Petersburg as Royal Commissioner. Dr. Hooker was informed that Lord Clarendon, after communicating with the Treasury, had declined to send him to St. Petersburg. He would ask leave to read his reply to Mr. Layard, then First Commissioner of the Board of Works, in which Dr. Hooker took her Majesty's Government to task with an amenity of language which showed that he was a good judge of style,—“I much regret this action of the Treasury . . . mere disregard of international courtesy in scientific matters.”

NOTES OF THE WEEK.

— ON Thursday evening, July 25th, and as Big Ben at Westminster was striking seven, a violent rain storm, accompanied by wind, took place in London and seriously damaged some of the fine young Plane trees on the Thames Embankment. These plane trees are strong and firmly planted, and supported by a cradle formed of three very strong stakes. A species of whirlwind of unusual force swept along the Embankment and twisted off the Planes as easily as if they were feeble reeds. In some cases the tree and its three great stakes were broken clean off within six inches of the ground; in one or two the head of the tree was broken clean off just above the line of the stakes, but in most instances the stakes were broken off, and the tree blown down, but not broken right off. In these cases the trees have been staked up again, and the wounds covered over with adhesive composition; specimens treated thus, show, as yet, no sign of suffering.

— AN interesting garden entertainment was given on Wednesday week to about 300 foreigners of the refugee and artisan class, by Mr. William Leaf, of Park Hill, Streatham.

— WE notice an improvement in connection with the seats in the London parks. A gently rounded granite slab is sunk in the ground by way of a foot rest, while the seats themselves rest on three smaller slabs placed at right angles to the foot rest.

— THE rare and fine *Grammatophyllum Ellisii* is now in flower in one of the orchid houses in the Royal Exotic Nurseries, King's Road, Chelsea. The flower shoot is nearly two feet long, and the racemes bear about forty flowers each.

— SOME beautiful hardy *Begonias* are now in flower in the Royal Exotic Nurseries, King's Road, Chelsea. They are unnamed seedlings, except one kind—*B. intermedia*. All are distinct and beautiful ornaments to the rock-garden.

— ONE of the prettiest and most graceful window plants which we have seen for a long time was a specimen of *Begonia Weltoniensis* shown by a cottager at the Willesden flower show last week. Though it had evidently been a long time under window culture, it was a sheet of bloom.

— *AMPELOPSIS TRICUSPIDATA* is rapidly proving its claim to be planted as extensively as the well-known Virginian Creeper. Mr. Dominy's house, in the Royal Exotic Nurseries, King's Road, Chelsea, is now a glistening sheet of it, from top to bottom, all nailed up too by its own tiny fingers. What a boon will this new creeper prove to all who have high walls to cover!

— Two new *Crotons* about to be sent out by Mr. William Bull are wonderfully fine in their way; one named *C. spiralis*, with foliage of a dark or bronze green, finely marked with yellow spots, has about as true a spiral leaf as is to be found in any class of plants in cultivation; the other, not yet named, has long, linear foliage more beautifully marked than anything of the kind we have yet seen. Mr. Bull has also a finely variegated form of *Erythrina*, the pure yellow markings of which instantly bring to mind the charming *Croton Hookerii*.

— THE cocoa-nut tree at Sion House, that fruited some years ago, is now throwing up a strong flower-spike, and will, we trust, under Mr. Woodbridge's care, produce and perfect another fruit.

— WE are glad to record that the noble *Musa Ensete* is holding its own out of doors this inclement season. Young plants of it are now fine ornaments to the London parks.

— IT may be interesting to know that Mr. Herbst, of Richmond, has just finished cutting flowers of Lily of the Valley from some hundred pots of it that came into flower during the first week in July.

— A GRACEFUL and touching thought has occurred to the promoters of the City flower show. Next year, according to an announcement made the other day, a prize is to be given for the best kept churchyard.

— THERE is now in flower in Mr. Bull's nursery, Chelsea, a number of plants of the beautiful and brilliant little *Lilium pulchellum*. This is no larger than *L. tenuifolium*, and deserves to be associated with that gem in every choice collection of hardy bulbs.

— THE finest plants of *Disa grandiflora* we have ever seen are now in flower in Mr. Salt's garden, at Ferniehurst, near Saltaire. They are grown in shallow pans, and, if we mistake not, enjoy rich manure as much as cabbages do.

— THOSE not familiar with the fine North American *Lilium superbum*, may be interested to learn that there is now a bed of it, and some closely allied forms, in Mr. Barr's experimental grounds at Tooting.

— ONE of the most beautiful bulbous plants in flower at the present time is *Zephyranthes Spofforthiana*, a good bed of which may be seen at Messrs. Henderson's nursery, Wellington Road, St. John's Wood. The plants are about six inches high, and produce large rose-coloured flowers in sufficient abundance to be very effective.

— IN one of the glass houses in the Royal Exotic Nurseries, King's Road, Chelsea, three *Allamandas*—*Schottii*, *nobilis*, and *grandiflora*—may now be seen in superb condition. They are planted out and trained loosely under the roof, and thus treated they present a more natural and attractive aspect than when grown in pots and trained on trellises.

— ON Monday last we saw specimens of *Amarantus salicifolius* two feet high, fine branching bushy plants beginning to assume a very high colour towards the top. These specimens were in a London garden, and have withstood all the recent severities of the weather; this is a sufficient proof that the constitution of the plant is all that could be desired for flower-gardening purposes.

— THE Lime tree has, notwithstanding the wet and cold season, already assumed a spotty half-withered appearance in many parts of London. The Lime should never be planted as a city tree in this country, for the simple reason that in cities it invariably assumes a scraggy, rusty, most disagreeable aspect three months before a town tree should do so. This does not apply in the open country, where it usually retains its good looks till late in the year.

— WE were glad to see, the other day, the beautiful white trumpet-shaped blooms of *Lilium longiflorum* peeping forth here and there from the *Rhododendron* beds near the Albert Memorial, in Kensington Gardens. This is certainly a step in the right direction; but we hope such features will not be overdone. If we have a bed, or several beds, embellished with a charming feature of this kind, the effect is weakened, in fact, it is entirely neutralised, by furnishing every bed in the place with the same subject.

— THE bright-flowered and pretty *Rhexia virginica*, one of the most beautiful of the bog plants of North America, is now in good flower in Messrs. Osborn's nursery at Fulham. It is very rarely seen in good condition in gardens. Although a member of the *Melastoma* order (which is composed, for the most part, of gorgeously coloured tender plants that abound in the warmer parts of America), this charming little plant, which inhabits the cold Northern States, is perfectly hardy in this country. It is called Meadow Beauty in America, and is one of the most valuable plants for the artificial bog, or for moist peaty spots in or near the rock-garden.

— THERE is now in flower in Mr. Peacock's fine collection of Cacti, at Sudbury House, Hammersmith, *Echinocactus Pottsii*, the extraordinary three-legged plant so much remarked at our principal shows this year. It is a gigantic globular kind about a foot in diameter, grafted on and supported by three stems of *Cereus tortuosus*, each about an inch through. One of the legs died not long ago, and Mr. Croucher added another in its place. It is the most curious result of the art of grafting we have seen.

— IN consequence of our extensive reports of the state of the fruit crops throughout the country appearing in the same issue with the monthly calendars of gardening operations, some of our illustrations are crowded out this week.

THE INDOOR GARDEN.

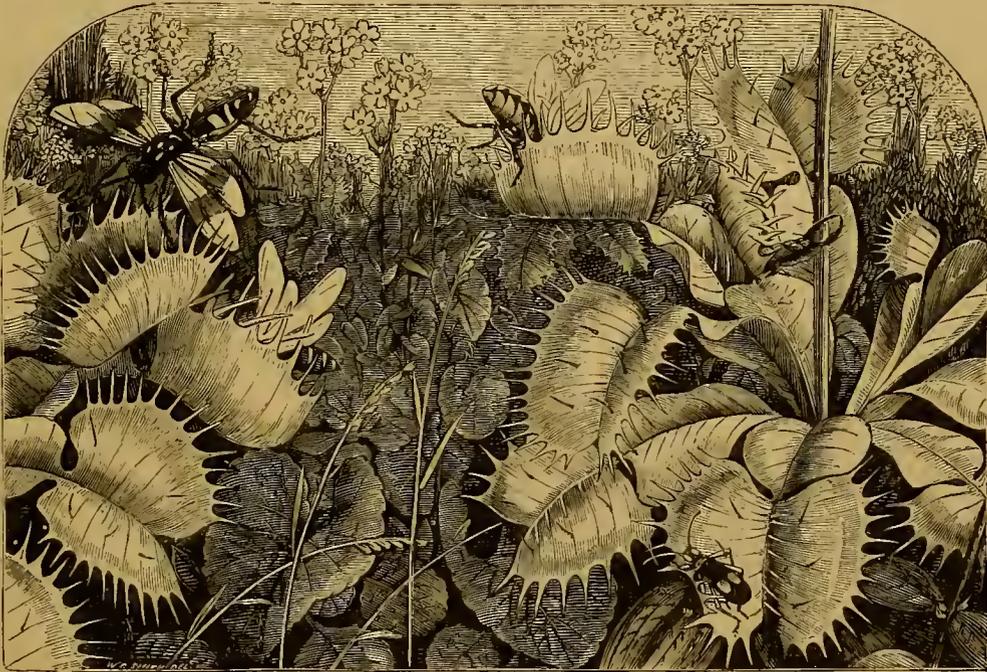

VENUS'S FLY-TRAP.

(*DIONÆA MUSCIPULA.*)

BY THOMAS BAINES, SOUTHGATE.

FEW plants are more generally interesting than this, either to people conversant with curiosities in the vegetable kingdom or to ordinary observers. It is referred to in most works on physiological botany, as affording a striking instance of vegetable irritability. The trap-like extremities of its leaves are so sensitive indeed, that the least touch causes them to close instantly on the luckless fly, wood-louse, or even larger insect that happens to get within their grasp. In the growing season, when the plant is strong, I have seen even a slug, four inches long, held fast by the tail until it was dead; and beetles so large as to protude on all sides from the trap also meet with a slow but certain death. This plant has, indeed, somewhat puzzled vegetable physiologists, some maintaining that its legitimate use in the vegetable world is that of an insect destroyer; others that it is carnivorous, and that it is benefited

little leaf mould, and sand. Pot tolerably firm, using thumb pots well drained; plunge these closely in sphagnum in a pot or pan sufficiently large to accommodate them, giving the whole a liberal watering. If strong, the plants will throw up flower stems; but these should be removed as soon as they are long enough to pinch out. During the season of growth water copiously every day. Towards November the plants will show signs of going to rest, by making a few short leaves; these will be retained during the winter, the larger summer leaves dying off. The soil must never be allowed to become dry, not even in winter, at which time the plants should be placed in a temperature of 50° by night, allowing a rise of some 10° during the daytime. During its season of growth it enjoys a night temperature of 60°, with 75° or 80° by day. Provided the atmosphere of the house (which should be moist) suits the plant, all the crowns that throw up flower-stems will be found to increase naturally by throwing off offsets. Many grow this plant under a bell-glass, but its growth is stronger without than with one. It likes a moderate amount of light, but no sun; therefore, if the house is thinly shaded, the plant should have in addition a piece of thin

Trap-like Appendages of Venus's Fly-Trap.

by the decomposed insects which it entombs. One thing we do know, which is that when a trap has enclosed an insect it retains its hold of it for weeks, or until the insect has become thoroughly decomposed; after that it re-opens. This natural insect destroyer is a humble marsh plant, bearing from the root, on a smooth leafless stalk a few inches high, a corymb of white flowers. From the bulb-like root proceeds, in a radiating manner, a number of leaves on longish stalks. The lamina of the leaf is divided by the mid-rib into two nearly semi-circular valves, each of which is fringed with stiff hairs, and furnished near the middle with three minute bristles arranged in a triangle, which bristles are extremely irritable, and when touched by a fly or other insect cause the two sides of the leaf to collapse with a sudden spring, imprisoning the intruder until it is either dead or ceases to move. It is a native of swamps in North Carolina, and is often to be met with in our stoves.

February or March is a good time to commence its culture. I have found it to grow well in the following materials: Three parts rotten sphagnum chopped fine, two parts fibrous peat broken small, one part broken crocks, the size of peas, a

tissue paper over it in bright weather. This is indispensable. About five years ago I had a large mass of this plant filling a twelve-inch pan. I gave it more light than is usually allowed it, and the traps assumed a beautiful bronzy colour, so much so, as to be remarked by all who saw it. The following year I thought to still improve it by placing it still nearer the light; but one week's bright weather so injured it that it never recovered. I should not advise anyone to commence the cultivation of this or similar subjects, such as *Cephalotus follicularis* or *Anæctochilus*, unless time can be spared to attend every day to their wants, or the result will be almost certain failure.

CULTURE OF HERBACEOUS CALCEOLARIAS.

BY GEO. BERRY, THE GARDENS, DALVEY, MORAYSHIRE.

THESE are best treated as biennials. The seed should be sown about the middle of June, and although I am aware that some make several sowings during the summer and early autumn, I would not recommend such a practice, for I have always been able to obtain a

good succession from the one sowing. After the summer bedding-plants have been put out, I prepare a corner in one of my spent dung frames, which were put up in the beginning of March for the purpose of striking cuttings in, and which a little later were used for starting Gloxinias, Achimenes, Caladiums, &c. In one of these frames, near the glass, I place my pan of *Calceolaria* seed, which is sown in a finely sifted compost of yellow loam, leaf mould, and silver sand. The seeds, which are scattered regularly over the surface, are barely covered with soil. A pane of glass is then placed over them, on the top of which a little damp moss is placed, but this is removed as soon as the seed begins to germinate. Shading, however, is always requisite while the plants are in a young state, to protect them from bright sunshine. As soon as they can be handled, I prepare a few pans or shallow boxes, which I half fill with open, rough material, such as refuse siftings; on these I put a sifted compost a little rougher than that used for the seed-pans, and also enriched a little by the addition of some decomposed hot-bed manure. Into these pans or boxes I prick off the seedlings an inch apart each way, and return them to their former quarters. To one particular point I attach much importance, and that is giving them plenty of air from their earliest stages of growth onwards. If this is not done, they are very likely to damp off. For this reason, then, I always place the seed-pan towards the front of the frame, and tilt up the latter a little both night and day. Should the weather be at all cold I protect the frames at night with a mat or two, according to circumstances. At each shift which the plants receive, however, the air is not left on at night for a day or two, but the first thing done early every morning is to remove the mats from the frames, and to give a little air; then, when the young pricked-off plants begin to meet, preparation must be made for another shift. For this, I use small thumb-pots, quite clean and well-drained; into these I put the young plants singly, preserving the roots and balls as much as possible; some require small pots and some larger ones, according to their respective sizes, and any too small to pot off are shifted to another pan, all being replaced in the frame. The compost used for this potting differs very little from that employed for the last shift. The plants now, however, require considerably more frame-room, and they should be set on a layer of clean sand. When this stage of growth is arrived at they do not require any covering at night beyond that of the sashes, but after they begin to take to the new soil, I tilt up the frames an inch or two both at back and front, in order to keep up a free circulation of air, and thus induce a nice stubby growth. After this no definite rules can be laid down for repotting. It is, however, a bad practice to over-pot, and still worse to pot such as do not require it.

After the second potting they should be gradually so inured to light and air as to do without protection of any kind. I always, however, preserve them from heavy showers and sudden changes of weather, by placing sashes over them, but they do not like too much heat; indeed, they grow far stronger during long cool nights than they do throughout the warmer and shorter ones.

There is no plant easier to winter safely than the *Calceolaria*, for if provided with a temperature of 34° it does very well. I grow annually about three hundred of these plants in the way just described, and nothing repays me better for my trouble. In October or November I transfer them from my frame ground to a span-roofed pit, which, being sunk into the ground four feet or so, is rather damp. The only means which I have of heating it is by means of a very small stove in the centre. This stove is, however, only used as a protection from very severe frost. I cover with wooden frames lined with straw. These will keep out frost of 7° or 8°, and even more. But if very severe weather sets in, I light a little fire in the stove just referred to every evening, never allowing the temperature, however, by this means to exceed 38°, nor to fall below 34°. This pit looks north-west and south-east, and has a shelved stage in the centre. On the sunny side I arrange *Calceolarias*, and on the other *Cinerarias*, wide enough apart to keep the leaves from coming in contact. Here both remain throughout the winter and until they begin to bloom. The winters are often so severe in this part of Scotland that the covers are not wholly removed from the sashes for three weeks together at a time; at such times every alternate one is lifted off at mid-day for three hours or so. If there is a heavy fall of snow, I prefer allowing the covers to remain untouched for several days, the snow being an additional protection. The moment a thaw comes, we remove the snow with broad wooden scrapers, and take off the covers; for if the snow was permitted to melt on the covers, it would so saturate them that the slightest frost would penetrate them in a short time. Under such conditions the plants continue to thrive, and by the middle of February many of them require another shift, which is generally the last they get, unless they are very vigorous, when I repot them again before they come into flower. During spring, unless the sun is very hot, no shading

is afforded them, and a free current of fresh air is allowed to pervade the pit night and day.

Calceolarias cannot withstand droughts, and over watering is equally injurious to them. Even throughout the most severe part of winter the roots must not suffer from want of water, but be kept always moderately moist. *Calceolarias* become dry sooner than most other plants, for even throughout the dull season they continue in growth, and the open, rough material used in potting when they are in an advanced state does not retain moisture long. Water should, however, never be allowed to touch the foliage, but should be given carefully, lifting up the lowermost leaves with one hand, and pouring in water gently with the other. Unless carefully handled the healthy leaves, which are so thick and brittle, break very easily. Should bright sunshine come in contact with a damp leaf, it becomes spotted, unsightly, and is very likely to damp off. For the last two or three shifts, I find two parts good yellow loam, one part thoroughly decayed hot-bed manure, and a little sharp river sand a good compost. These are all chopped up, well mixed, and used in a rough unsifted state. I usually pot all requiring a shift before taking them into the pit; but the size of the pots must be regulated according to the size and vigour of the plant; therefore, at the blooming season some may be in six-inch pots, and others in twelve-inch ones. We commonly go over them about the 1st of May, stake all that require that attention, and bring them up to our blooming house. They get another staking about the end of May. In order to prolong their flowering period, and to bring the blooms to perfection, I give them occasional applications of guano-water. This invigorates them, and brings out that fine deep green in the foliage which is so desirable. Pot-bound plants in particular are exceedingly grateful for liquid manure; but to such as are over potted, it must be very sparingly supplied. When the blooms begin to fade, I turn the plants out, clear them of their stakes, pots, and crocks, break up the ball, and throw it on the vegetable heap. If I want to preserve a remarkably fine sort for next year, as soon as its beauty is over I cut off all the flower spikes, and transfer the plant for a time to a frame with a north aspect, or place it on a board behind a wall; after a time I shake it out of its present pot, shift it into a smaller one, place it in an open cold frame, and afterwards treat it as any of the others; it is never under glass until housed for the winter. Green fly is the greatest enemy which the *Calceolaria* has in the way of insect pests, but well-grown plants are seldom troubled with it, and should they be attacked, tobacco fumigation soon clears them.

GOMPHOLOBIUM POLYMORPHUM.

ALTHOUGH this is one of the most beautiful of greenhouse climbers, and a plant which, when properly managed, remains in beauty longer than most things, and is equally valuable for exhibition or decorative purposes, yet it is rarely seen in anything like perfection. The first time I saw a well-grown plant of it was at the Horticultural Society's exhibition at Chiswick in May 1847; this was exhibited by the late Mr. Hunt, then gardener to Miss Traill, and was trained upon a half-round wire trellis, four feet in diameter, which was clothed from top to bottom with delicate foliage and bright red pea-shaped flowers, together with multitudes of buds in all stages of forwardness; it was awarded (and justly) an extra first prize or gold medal. I, as well as other plant growers who saw it, admired it greatly, and considered it well deserving the high award it received; but I thought that if it could be trained upon slender stakes in the bush form, it would look more natural, have a more graceful appearance, and correspond better with other plants when staged among them in a collection; for much as I admired the plant shown by Mr. Hunt, I could not help thinking that, trained as it was, it had an appearance of stiffness and formality which greatly detracted from its beauty. I soon found an opportunity of trying what could be done in growing a specimen of this without the assistance of a wire trellis, and succeeded to my own satisfaction, as well as that of all who saw it.

Persons intending to commence the culture of this *Gompholobium* should procure young plants as soon as possible, choosing those that are clean, strong, and healthy-looking, and which appear to be well rooted and firm about the collar. In choosing young plants to be grown into specimens, it will be found to repay the trouble to see that they have their stems or collar strong in proportion to the size and strength of the rest of the plant, which is often delicate; and if plants which are not perfectly sound in the stem are selected, their progress will never be satisfactory, and the chances are they will not live to attain any useful size. Directly the young plants are received, they should be repotted and placed in an intermediate house, where a nice moist temperature of about 55° is maintained. In potting young stock for starting, I prefer giving a liberal shift, say from a three-inch

pot to an eight-inch one, which allows more space for placing the stakes for training shoots upon. A few slender green stakes, according to the size of the plant, should be placed in the soil at once, and the shoots trained round them, taking care to cover the bottom with the likeliest shoots for breaking strongly. In potting now, and on all future occasions, care must be exercised to have the ball of the plant in a healthy state as to moisture and also the new soil; great care must also be used in watering, especially until the roots can strike into the fresh soil; and the atmosphere should be kept rather closer and moister at this time, so as to avoid as much as possible the necessity of frequent waterings, and to encourage active growth. Keep the plants near the glass, and as soon as the sun becomes powerful, a thin shade must be used, for this variety is impatient of exposure to bright sunshine, and anything approaching free vigorous growth need not be expected, unless it is shaded; and although air should be admitted whenever this can be done without cooling the temperature below 55° or 60°, yet this should be done very cautiously at all seasons, and especially during the prevalence of drying winds, so as to avoid draughts—for a current of cold drying air playing upon a plant for a few hours when it is in free growth would sadly check its progress or probably ruin it. Hence, while air should be admitted freely on every favourable opportunity, this must be done so as to avoid draughts or cause cold currents to pass through the plants; during bright warm weather, however, sufficient ventilation must be given to prevent weakly growth, and the plants should be moistened overhead two or three times a day, and the atmosphere kept damp by frequently sprinkling the passages, &c. If the plants do well the first season, they will form nice little bushes, and will fill their pots with roots; but they must have frequent attention in the way of training their shoots, for if these are allowed to twine upon each other, neither the wood nor the foliage will be properly developed; and although training may prove a rather tedious part of the attention required to grow this plant properly, it must be attended to, and this is a formidable job enough; but when the young growths are not allowed to become entangled, it will not occupy much time if done, as it should be, at short intervals, adding extra stakes as may be required. I generally remove my young plants to the hardening greenhouse in August, placing them where they will not be exposed to through draughts of dry air, and by gradually reducing the moisture in the atmosphere, &c., the wood will get sufficiently ripened to stand the winter, and the plants will continue growing slowly until November, when they may be safely wintered in an ordinary greenhouse, but they must not be exposed to cold frosty winds, and drip should not be allowed to fall upon them; and as the plants, too, during the winter, will be in a comparatively inactive state, they must be carefully watered at the root, keeping them rather on the side of dryness than otherwise, but when water is applied enough should be given to moisten the whole of the ball. The treatment during the second season should be similar to what has been recommended for the first, repotting early in March, giving a rather liberal shift, re-staking and training, placing them in an intermediate house, and attending to them throughout the season as recommended above; if very large specimens are desired, a third season's growth will probably be necessary to produce them. When the plants have reached the desired size, if they are wanted for purposes of exhibition, it will be necessary to use means to secure having them in the greatest possible beauty at the proper time; to be successful, you must not only be able to grow handsome specimens, but also to have them in full beauty on a given day. As a rule, I leave specimens of those which I intend for exhibition in the greenhouse until April, and then remove them to the intermediate house, earlier or later in the month, according to the state of the plants and the time when they may be required. But as to the time at which a plant can be brought into beauty, this can be easily learned by careful observation for a season or two—and by that means only—for a healthy plant, with its pot well filled with active roots, will be in full bloom before another with imperfectly ripened wood, and not over healthy or active roots, will show any symptoms of having felt the excitement, which, if it had been in perfect health, would have been sufficient to have induced it to put on its best appearance. For plants in a sound healthy state, with well ripened wood, from a fortnight to a month in the intermediate house will be sufficient to bring them into full beauty; but others, with imperfectly matured roots, may require longer. I can, however, only say that there can be no mistake in having the plants early enough, for a vigorous plant of this *Gompholobium* will be in full beauty for a month at a time at least.

The soil which I find to be most suitable is the light fibrous kind of peat found in Kent; this, broken up moderately fine, and cleared from excess of fibre and strong decayed roots, and mixed with about one-fourth its bulk of Reigate sand is the compost I use. In potting, care should be taken to have the soil in a proper state as to

dampness. I use soil just moist enough to bear compressing in the hand without sticking together or readily falling to pieces; and, in potting, the fresh soil should be pressed about the ball, so as to make it as nearly as possible in the same state as to water as the ball of the plant. There are two other twining varieties of *Gompholobium* well deserving a place in every collection, viz., *G. splendens*, which, when grown in the form of a bush, and clothed with its clear bright yellow blossoms, is one of the most charming plants I know of, and *G. versicolor*, the blossoms of which are large, and remarkably striking.—W. M.

LONDON GARDENS.

THOSE prim Roman horticulturists who gave birth, through later Italians, Spaniards, and Flemish, to the Dutch ideal of Nassau William, have much to answer for to modern citizens of Cockaigne—much in the way of sanitary loss, and more in that of artistic culture and mental recreation. We have to thank Virgil, the *irréconciliable* uprooter, for many miles of bare brown mould, and rood after rood of naked grey-brick walls, bordering habitations that are assuredly in some need of relief and ornament, in thoroughfares of the city that might have been made gay and gracious. There is not in London the excuse that could be alleged for such a state of things in Paris, Berlin, or nearly every capital of Europe, with the exception of Vienna. London possesses more open spaces than any of these cities; and it does not grow inwards, compress its streets, raise its houses, curtail its gardens; but spreads outwards into suburb after suburb. What could not be made of these facilities for brightening the aspect and purifying the atmosphere of the legendary *ville vaporeuse*? Long lines of Corisande's gardens, small wildernesses, after neglected Bacon's plan, could be made to yield not a little corporeal and æsthetic enjoyment. But the great aim of the Cockney gardener is neatness, not health or beauty *pure et simple*. So that his small estate is free from broken bottles and rubbish, he is content that it shall be free from flowers also during the greater part of the year. He enjoys the blank surface of black mould, the trim bare shrubbery, where not one dead leaf remains half a day, the clean gravel walks and regular box borders, all arranged with the painful nicety of a Flemish kitchen garden. But Flemish kitchen gardens produce very acceptable viands at times, and the city horticulturist's domain contains nothing. It is dingy, dull, and wet and naked in winter, spring, and early summer. When the bedding-out period arrives, the professional nurseryman is communicated with, and sends in a cartload of petunias, verbenas, geraniums, and the like, to clothe the desert gorgeously for about six weeks or two months in the year. The result is a meagre, formal prettiness of the old Keepsake, or Souvenir fashion—a prim, pruned, and, as it were, starched and whaleboned beauty of the class that looks well in the family portrait gallery, but with which one scarcely cares to form an intimate connection. The same system of planting is followed in nearly all parks and squares. In the vast majority of great seigneurial pleasaunces the same facts are observable. They are bare the greater part of the year, until the owners desire to make a display before their guests at the shooting season. Their aspects are imitated by all the ignorant amateurs who have charge of what should be oases of beauty and ornament in numberless urban thoroughfares. Women with a chastened taste for the pastoral have charge of all; and they are swindled and brow-beaten by the professional gardener, and inoculated with the severe notions of the small local *Le Nôtres*. They hold box sacred as Druid's ivy, a brick wall a necessary horizon, a spick-and-span lawn and weedless beds the highest possible attainment of art, and the brief blaze of geraniums once a year the very apotheosis of all horticultural success. Hideous as such culture makes them, it is no matter for wonder that scarcely any proprietors of urban gardens ever make the slightest use of their domains for purposes of rest, exercise, or recreation. There is no school in Great Britain at which the elements of garden culture are taught, yet a change would be easy and inexpensive. No deep education is needed, for instance, to devise an improvement on the blank walls, which suggest the next-door neighbour as a creature to be more guarded against than the chance acquaintance of a foreign *table d'hôte*, or a stranger in a railway carriage who proposes cards. Against the smoky, gloomy, grey bricks a bank of mould can be raised, and bushes, flowers, creepers, planted thereon, so as to almost give the idea that a Clapham back garden is bounded by the primeval forest. An immense variety might be achieved in the smallest villa back gardens. Since it is seemingly ineradicably British to have a weakness for wall-paper patterns in beds, they can be retained, they and the masses of colour; but other nooks can be devoted to informality, change, and indefinite variety.—G

PUBLIC GARDENS.

PARIS PUBLIC GARDENS IN 1872.

THE base uses to which ornamental grounds may come at last were strikingly illustrated by the fate of the Paris parks and squares in the evil days which visited the city after Sedan. None of these familiar and cherished oases were absolutely destroyed, but all were more or less battered, and made to serve purposes which the Emperor Napoleon's Prefect of the Seine never contemplated. The garden of the Tuileries was turned into a military camp and a point of departure for the balloon-post; the Luxembourg Garden was made a cattle-yard; ambulances and oxen shared the space enclosed by the Jardin des Plantes; parks of artillery were massed in the square of Notre Dame and the Place Royale; the parks of the Buttes Chaumont and Monceaux, and the squares at Batignolles and Montholon were utilised as depots for petroleum, while other of the larger squares, such as those of Belleville and the Arts-et-Métiers, became drill-grounds for the National Guards. Under the Commune the parks, gardens, and squares suffered more even than during the investment of Paris by the Germans, and when, after the defeat of the Commune, M. Alphand was enabled to resume the direction of the public parks, he found them in a condition calculated to induce despair in the mind of any but the most resolute landscape gardener. The work of resuscitation was, however, boldly commenced, and in the gardens of the Tuileries and the Luxembourg young trees were planted in the numerous empty places which the fortunes of war had created. The same thing has been done in the Cours la Reine, the avenue of the Champs Elysée and along the old exterior boulevards, the work of replanting meanwhile rapidly going on in all the smaller green places of the city. Some of them have already assumed their normal aspect, and look as fresh and bright as if there had been no siege of Paris and no burning of the public buildings.

The park of the Buttes Chaumont was a remarkably warm place during the assault by the Versailles troops. The insurgents left it with three batteries, commanded by the Count Raoul du Bisson, the cannon of the Versailles firing upon them without intermission, it being estimated that 30,000 shells fell upon the park during the struggle. This hail did not do so much damage to the park itself as might have been expected, the greater number of the shells burying themselves in the ground. But the pavilions of the Guards and the Café de Puebla were demolished, and the basin of the lake was shattered in various places. To day nothing remains to bear witness to the fierceness of the fight. The pavilions have been rebuilt, the café patched up and painted, and the lake which, in September 1870, served as a magazine for petroleum, and on the 27th of May in the following year formed a grave for a hundred insurgents taken red-handed in the park, has been repaired. The only souvenir of the insurrection which the parks afford is to be found near the Café Puebla, where rises a little column of exploded shells. The Monceaux park has been repaired with equal promptitude and completeness. The big trench dug for the storage of petroleum barrels has been filled up and turfed, the garden beds have been dug up and raked over, the trees trimmed, and the spot where, on the 21st of May 1871, the three Italians and the three deserters from the regular army were shot and buried, has already become a tradition, involving a difference of opinion as to the precise locality of the temporary grave.

The squares of the Tour Saint Jacques, de Montronge, des Invalides, de la Place Louvois, de la Place Royale, de la Place Laborde, de la Place Vintimille, de Sainte Clotilde, de la Rue Mouge, and du Temple are amongst those which have suffered least by the incidents of the two sieges. The grass-plots and the flower-beds were trampled on, and in some cases the trees slightly injured; but a few days' work served to put them right again. The squares of the Batignolles, the Innocents, and Montholon have been repaired, and in the last-named the large trees have been pruned and trimmed. The fountain of the nymphs, which adorns the centre of the Square des Innocents, was struck by a shell and some of the sculptured work broken off. This has been remodelled, and the square swept and garnished. In the Square des Batignolles the breaches made in the basin of the fountain have been prepared, and the parterres re-sown with flowers. The deep trench for petroleum which ran across the main sward has been filled up, a slight depression of the ground alone marking its former course. On the side which borders the Place des Batignolles is shown the spot where were "provisionally" interred fourteen insurgents taken with arms in their hands behind a barricade. The squares which suffered most severely were those of Belleville, the Arts-et-Métiers, and Notre Dame. The Square des Arts-et-Métiers has been rendered passable. In more peaceful days this square was notable for an immense border of rhododendrons,

but for some inscrutable reason these have been transplanted to the Bois de Boulogne, and have been replaced upon three sides of the square by a fringe of ivy. As to the old square of Belleville nothing remains of it, the Administration having found it necessary to remake it entirely. It was here that the insurgents, elsewhere utterly beaten, made their last stand. The fight commenced at two o'clock in the afternoon of the Saturday, and lasted throughout the night, the firing not ceasing till nearly ten on Sunday morning. When all was finished they found dead in the square seven insurgents, eleven soldiers, and three horses—not a heavy return for a fusillade of twenty hours' duration. But if the combatants escaped with small loss, the trees suffered seriously, there not being one in the square that has not its wounds to show. These form the most striking evidence which the Paris parks and squares afford of all the city has gone through since September 4, 1870, and it must be confessed that they are not much. A bullet-hole in a big tree is not easily found by an anxious tourist, and, when found, seems hardly worth while making a note of in a city where bullet-marks must by this time be as common as chimney-pots amongst less emotional communities.—*Graphic*.

DRINKING FOUNTAINS IN KEW GARDENS.

A CORRESPONDENT of the *Times* calls attention to the very small supply of drinking water there is in the much crowded gardens at Kew. "To make the circuit of the gardens, visiting in order the several houses and museums, and giving fair time to each, occupies from two to three hours of almost continuous motion; and in hot summer weather, especially with children, much thirst, which practically there is no means of quenching, is the inevitable consequence. There are, it is true, three drinking fountains, but of these one is outside the gates, one at the end of a wall at the side of the gardens, and the third in the arboretum, which also is practically outside, and not one, I believe, near the houses; so that, while surrounded by water-pipes, not a drop of water can be obtained for drinking, except by leaving the gardens or traversing almost their entire width for that purpose. Even when the fountains are reached, the supply they afford is totally inadequate to the demand, and the mere process of drawing and drinking the water occupies so much time as to tire the patience of even the least importunate, when numbers are in want." [We have often witnessed this difficulty at Kew, and hope it may soon be remedied. The few absurd little drinking fountains at present there are mere apologies for those that are really wanted.]

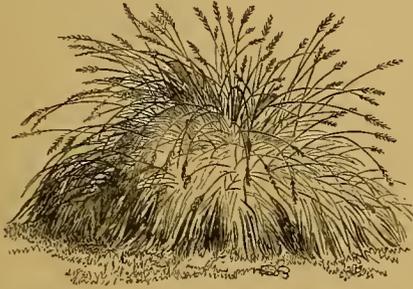

Railings.—No one who walks along the Strand can fail to see how vastly the church of St. Mary-le-Strand is improved in appearance by the removal of the railings which surrounded it. And assuredly, in the present scarcity of iron, we could well spare the railings which now sadly mar the architectural effect of St. Paul's Cathedral. What, indeed, is the use of half the railings of London? The noble owner of Ebury Square is going to set a great example by turning the square into a public garden, and it is impossible to over-estimate the boon which might be conferred upon the people of London if the example were generally followed. We do not believe that it would be generally abused. There are some obvious considerations which might prevent the abolition of park railings, but we are confident that the men who shall combine together to wage war against every needless railing, would be among the benefactors of their race. For, considered artistically, the railing is an eyesore; considered economically it represents a waste of iron and labour; considered as a protection against the burglar it is inoperative; considered with regard to the public freedom it is a nuisance. Let reformers arise to beat these spears into pruning-hooks, or any other useful articles for which there is a demand.

Vegetation in Towns.—Of Chinese and Japanese plants for town ornamentation I have the greatest hope (Conifers alone excepted); and this mention of Conifers reminds me that I shall be glad to discuss how far the classification into natural orders is a safe guide for satisfactory suburban planting. Take two extremes: nearly all Coniferae fail, while nearly all Saxifragaceae thrive. On the other hand, the vitality and smoke-enduring powers of that varied but most ornamental order Rosaceae vary very much. *Cistus laurifolius* does pretty well, and is now in full bloom. *Lithospermum prostratum* was not cut off or materially injured by the late spring frost of this year, in the midland counties. *Dimorphanthus mandshuricus* (which I take to be *Aralia spinosa*) looks as well as anything in the garden, and looks like a noble relative of the various plants of *Rhus typhina*, *Raphiolepis*, or the *Skimmias*. *Ligustrum japonicum* and *coriaceum* are perfectly hardy, and, like *Rhododendrons*, accept resignedly a thick winter coating of soot, and cheerfully push out new growth, strangely contrasting in colour with the old leaves. *Daphne Flouiana* (or *Neapolitana*) is a perfect gem, and bears ten times as many flowers when planted out as it did before its escape from the greenhouse.—W. T.

THE FLOWER GARDEN.

POA FERTILIS.

Just within the main entrance of the Royal Gardens at Kew, a very graceful-looking grass might have been seen isolated on the turf during the past few years. It is a comparatively dwarf subject, and not at all striking in bloom like the Pampas, but with a very distinct and desirable plant. It is one of the most elegant of grasses, forming dense tufts of long, soft, smooth, slender leaves, which arch outwards and downwards in the most graceful manner on every side, and, in the flowering season, are surmounted by airy, diffuse purplish or violet-tinted panicles, rising to a height of from twenty inches to three feet, the grassy tufts being usually about half that height. This plant is widely distributed over Southern Europe, Northern Asia, and North America, in wet meadows and on low banks of streams. Of all the dwarf perennial

Poa fertilis.

grasses it is perhaps the best for isolation on grass, where its fine dense and graceful tufts of long hair-like leaves and elegant panicles form quite a distinct-looking and ornamental object.

SUMMER TREATMENT OF CARNATIONS AND PICOTEEES.

To insure good bloom both Carnations and Picotees now demand particular attention. Disbudding, if not already done, should be at once effected, leaving on two, three, or four buds, as may be required. If they are grown for exhibition purposes, two blooms will be sufficient; but if not, a larger number may be left. Green-fly is sometimes at this season very troublesome. It should either be brushed off with a soft brush, or the affected parts should be dusted over with Pooley's tobacco powder, which should be used early in the morning while the dew is on the "grass." If the insects are very numerous, and means for fumigating are available, let this be done, as it is the most effectual remedy. During the time the buds are swelling, a little weak manure water may be given about twice a week. As soon as the buds become sufficiently full, they will require tying. The plants should be looked over every day, and those buds that are quite full should have a narrow strip of bast tied tightly round the middle of each pod, at the same time opening each division of the calyx; this latter is a very great assistance to them, and will often save a pod from splitting, even if it is not tied at all. By thus keeping the pods from splitting, the blooms keep much more compact and circular in form. As soon as any of the blooms begin to open, they should be protected from rain. This may be accomplished by setting the plants in a greenhouse, provided plenty of air can be given, which is very essential. Constant attention to watering is also absolutely necessary during the time they are in bloom, so as not to allow them to get too dry. They should be shaded from the sun, but should have as much light and air as possible at all times. Should the weather be hot and dry, the foliage should be sprinkled one or twice a day, avoiding to wet the blooms. This will be a great assistance, and will help to prolong the bloom. When the plants have done flowering, they should be returned to the open air, so as to get the shoots in good condition for layering, which operation should be performed early in August. The process, which is a very simple one, is this:—Prepare some light, rich, sandy soil; stir the soil out of the pots to a depth of about two inches, and fill up with the prepared soil; the layers should then have the leaves cut off to within the third or fourth joint from the top; then take the layer in the left hand, and with a very sharp knife make an incision in the under side, beginning about half an inch below the

third joint, and extending it upwards through the centre of the stem, about half an inch past the third joint, cutting off the lower end or heel of this "tongue" just below the joint. The layer will then require to be pegged down. A most suitable peg for this purpose can be made from the common brake fern used in a green state. Take care not to press the layers more than half an inch deep in the soil, as they root much better when shallow, and keep them as upright as possible. In dry weather they should be frequently sprinkled with a fine rose water-pot, so as to keep the soil in a moist state. In about a month or six weeks they will be sufficiently rooted to be taken off and potted into small pots.—*John Ball, Slough, in "Florist."*

BRIAR OR MANETTI ROSES.

MAY I ask my brother rosarians two questions? 1. Is the maiden bloom of the briar superior to that of the Manetti? 2. Does not a two or three year old rose on the Manetti often produce blooms equal to the maiden blooms of either briar or Manetti? Mr. Reynolds Hole, in his most interesting and amusing book on roses, lays down two laws, first, that the maiden bloom on the briar is superior to that of the Manetti, and that this fact is generally granted; and, second, "If you propose to grow roses for exhibition, i.e., to grow them in their full perfection, you must grow them on your own stocks from buds." Now, I have the very highest opinion of Mr. Hole's judgment; his book I know by heart, and it certainly has made me a rosarian; but yet, with all deference and humility, I must say I doubt both of the above statements. My experience proves the contrary to both his premises, but more especially to the latter. If I had not proved that roses bought from nurserymen last year won first prizes this summer at Hereford and the Crystal Palace, I should be very reluctant to doubt for one moment Mr. Hole's statement, but in all my stands this year I never showed one maiden bloom. Indeed, I could not, for I had none to show; my trees were so backward that they are only blooming now, the third week of July. Last year, Mr. Baker, of Heavitree, won nearly every first prize at the Crystal Palace and Hereford, and he did not show one maiden bloom, for the good reason that he does not bud either briar or Manetti. He beat all the nurserymen at the Exeter rose show last year, and they, of course, were showing nothing but maiden blooms. But with regard to the question as to which is the best, the maiden bloom on the briar or Manetti, I desire information very much, for I cannot myself see that the question is foregone in favour of the briar.

JOHN B. M. CAMM.

Monkton, Wyld, Charmouth.

HEPATICAS.

My collection of these comprises the fine and showy *H. angulosa*; a fine purplish mauve-coloured variety, which I received under the name of "single mauve," and which I have also met with under the name of *H. Barlowii*; the single blue, red, and white varieties; and the double forms of the first two, namely, the blue and red. The single varieties are very pretty indeed; but whether for pot or border culture, the double flowers are to be preferred, as they continue much longer in bloom. It has always struck me that the double varieties are more floriferous than the single ones. An east aspect, and a deep, strong, loamy soil, suit the Hepaticas best. In old gardens I have frequently met with splendid clumps of them, growing on the edges of shrubbery borders, sheltered considerably by means of overhanging branches, and yearly fed by the decaying leaves that fall so plentifully about them in the autumn. Such conditions as these appear to minister to their welfare in the highest degree. During last spring I met with some long-established clumps in the garden of a farmhouse in Kent, on a somewhat open and sunny spot, but in a soil that produced fine hops—a deep, holding, yellow loam, resting in a cool bottom. I attempted to dig up one of these clumps, and found the roots had struck down deeply into the soil—quite a foot in depth; and therein, no doubt, lies one secret at least of their well-doing. It is in the very nature of the Hepatica to strike its roots down deeply; consequently plants of it seldom succeed in a shallow soil, and never in a dry, hot one. The hardest frost or the most searching cold does the plants no injury; if they die, it is invariably from some cause over which the cultivator has control. I am not aware that any systematic attempt has ever been made to improve the varieties of Hepatica by means of seed. As self-sown seedlings appear to be not uncommon, it may be that some intelligent fertilisation might accomplish more than is generally supposed. As, however, particular varieties cannot be depended on to come true from seed, it is necessary to resort to root division. In this manner the Hepatica is readily propagated, and immediately after blooming,

Just when the plants are actively engaged in the production of leaves, is the best time for the operation. If well rooted, single eyes will make good plants by the following season, and they should be planted in a bed of deep and rather light loam, which should be in a position accessible only to the morning sun. Cultivators of the *Hepatica* recommend that the plants should be parted not oftener than once in three or four years, as frequent divisions are apt to weaken them, and cause some to die. In cases where *Hepaticas* are largely used for the spring garden, and where they have to be removed to make way for the summer bedding plants, it is well to have a reserve border in a suitable place, and there should be plants enough to allow of only one-third being used each season. This reserve garden need not occupy a large space, and, if managed in the way indicated, would always yield a supply of strong three-year-old plants for the embellishment of the spring garden. A few should be grown in pots and wintered in cold frames, both for the sake of their charming flowers and for their usefulness for house decoration. It would suffice to repot these about once in two or three years, according to the size of the plants; and this also should regulate the times of their occasional division. When repotted, and when out of flower, they should occupy a position in an east border well shaded by trees, and should be set on some coal ashes. Watering must not be neglected during dry weather, especially when the plants are maturing their growth. A few blooms of *Hepaticas* make a charming button-hole, and the double flowers last a long time. Q.

A Wall Rose Garden.—I have lately seen, as I did last year at the same season, two walls completely covered over with Banksian roses, which have flowered abundantly in their season, and which are now well furnished with flowers of different varieties of Tea Roses, Bourbons, and Hybrids, in various colours. These, I need hardly say, produce the most beautiful effect. This result has been obtained by grafting on the Banksian, varieties such as General Jacqueminot, Souvenir de la Malmaison, &c., giving the preference to the more vigorous kinds. The grafts and buds having taken, the branches of the Banksian were bent down, and the shoot soon developed itself with great vigour. [We take the above from the *Revue Horticole*. A wall embellished thus must be very beautiful, and we recommend the practice to those possessing well-covered walls of Banksian Roses.]

Acacia dealbata.—What a lovely wall plant this is! Talk about the grace of a fern—there are very few ferns that equal it, except we go to such as *Leptopteris superba*. The great beauty of its foliage is most apparent when the plant is growing freely in the open air, as I saw it the other day in Mr. Harrison's garden at Weybridge Heath. It is one of the finest of all subjects to plant against a sunny wall, wherever the soil is warm and well drained. To train it rigidly is of course to rob it of all grace. The main stems should be affixed to the wall, and the others allowed to grow forth in their own way. The plant will sometimes be cut down by frost, but it will spring up again. This occasional and partial destruction is really a gain instead of a hindrance to the enjoyment of the plant. When destroyed to the surface of the ground, it sends up more vigorous shoots and more beautiful leaves than are produced by old plants in a favoured clime.—W.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Rose Bessie Johnson.—Messrs. Curtis, Torquay, exhibited a box of twelve blooms of this beautiful new blush rose at the late Crystal Palace rose show, where it received, as it deserved, a first-class certificate. Its fine form and sweet perfume attracted general attention, and it is said to be as hardy and free flowering as *Abel Grand*, which is one of its parents.

Asclepias princeps.—I noticed a good species of *Asclepias* flowering in one of the London nurseries the other day, a sort that seems to me to be one of the best in cultivation. It was named *A. princeps*, but it seemed to agree best with the species described as *A. incarnata*. It grows about three and a half feet high, and produces purplish red flowers freely on the top of the stem, and for this reason appears the most useful kind for garden purposes, as the flowers of *A. Coruzzi*, *Douglasi*, and *speciosa* are almost hidden by their foliage.—T. S.

The Large Evening Primroses.—How beautiful are the tall and large-flowered *Oenotheras* that now so conspicuously adorn many of our gardens. It should be generally known that these plants will grow in any wild or rough place associated with the foxglove and the willow-herb. Seed may be sown now to secure plants to bloom next year. We lately enjoyed a moonlight ramble among quite a forest of these noble night bloomers at Glen Andrea, that have been very lovely for many weeks past.

Watering and Mulching.—A good deal towards securing continuity of bloom and vigour of plant may be done now by keeping the earth cool and moist. Copious waterings and mulchings or surface coverings will help to do this. For the latter purpose coco-nut fibre or moss is the most suitable in the flower garden. Any rough, slow-conducting material will check the penetrating powers of the hot, thirsty sunbeams, and thus prevent the earth from being unduly heated or too much baked, and its moisture from being stolen and given to the air.

THE GARDEN IN THE HOUSE.

WINDOW PLANTS.

BY J. C. NIVEN, BOTANIC GARDENS, HULL.

(Concluded from p. 70.)

GENERAL REMARKS AND SUGGESTIONS.

THE usual position occupied by window plants in general is on the ledge, outside in the summer time, inside in the winter. In both cases it will be advisable to have some protection, so as to prevent the plants from toppling into the streets on the one hand, or, on the other hand, on to the floor of the room. Any neat little fancy guard will do inside, but I would suggest for the outside a box made sufficiently wide to overhang the window-sill by two or three inches, and to be six inches deep. In this the pots might be set, and surrounded with sand or ashes, or, better still, with soil; and if the latter, then at each end a few seeds of climbing *Nasturtium*, or *Convolvulus major*, or both mixed together, may be set, and by adjusting a few strings, may be trained up the sides of the window and festooned across the top. Not only is this desirable result and additional attraction to the room window attained by adopting the box arrangement outside, but the pots, plunged in the cool material, will not require nearly so much water and attention as when exposed over their whole surface to the action of a blazing summer's sun, which must be the case on an unprotected window ledge. *Ventilation* is a necessity as well in winter as in summer, and though in newly constructed houses the windows are usually made to open above as well as below, still in many of older date the lower sash only is movable, hence, when opened, the plants are placed in a draught. This is alike prejudicial to the health of plants and human beings, especially in winter. So if the temperature outside is very cold, set your plants either on one side or on the floor, replacing them after you close the window; but if the air be mild you can close the door, throw the window well up, the higher the opening the less the draught, and leave the plants to enjoy the fresh breeze. Never put your plants on a high shelf, so as to be "out of the way," during night, as the higher their position the hotter is the atmosphere in which they have to exist; consequently the plant is robbed of its fluids by an unnatural evaporation. These remarks are especially applicable to rooms in which gas is used. Rather place your plants on the floor. During summer, if you cannot arrange for your plants outside on the window-ledge as previously suggested, it will not be much trouble to turn them out of doors every night, even if it is only into a backyard. The cool refreshing dew of heaven is, in the absence of rain, nature's great restorer of exhausted energies. Leaves, as I before stated, exercise during the day their power of evaporating moisture, but they have likewise the power of absorbing moisture during the night. With the coolness then prevailing the moisture becomes condensed on their surface and forms dew.

Plants in a room are sure to have their leaves coated over with a deposit of dust. Where the leaves are smooth, or, I ought to say shiny, this may be readily removed by washing; but where the leaves are soft and covered with hairs, some injury is sure to be done, be the hand ever so gentle that applies the sponge. However, the injury will do less harm than the dirt incrusting the leaves; and as it is much easier to keep one's own face thoroughly clean by washing it every day, so with your plants, in a room especially where fires are in constant use, wash them often, say at least once a week, and before the leaves are dry, sprinkle them well with clean water. When you syringe your plant always lay it on its side; the water used in this process will not then run into the flower-pot. If it does you may get your plant what is called "water-logged." In the summer-time a day's rain, gentle and continuous—nature's shower bath—will be more effectual than sponging and syringing, even by the most loving hands. So in summer never let your plants miss a general shower.

A WORD NOW ABOUT INSECTS.

All plants are subject to these pests, some more, some less; but take this as a truism that the healthier and more vigorous the plant the less liable it is to the attacks of insects. Of these perhaps, the greatest pest is the green fly, to the development of which the usually dry air of a dwelling-room is highly conducive; and when I say that they live on the juices of the plant, it will be obvious that they must be detrimental to plant life. They are robbers of your plant stores, and war must be waged against them. Now what is the best mode of annihilation? If you can only catch the first one that appears, and a sharp eye can do this, give him a "pressing" invitation to depart. If ever you notice a curled leaf or part of a leaf, examine it carefully below, and mind, "notice to quit at once" must be given, because a day's delay may give you a small colony. Supposing you miss insect No. 1, and find a colony

established, nay, perhaps several colonies, before you have noticed them, what is to be done? Take it as a broad principle that they hate tobacco, whether in smoke, water, or snuff. The most effectual form of applying tobacco is in smoke, as it then finds its way into every crevice and corner. But it will not avail to get the master to merely puff at the deprecators as he is enjoying his pipe of an evening; they would laugh in their sleeves at that, if they had any. They must have something more concentrated. Then what's to be done? You have a washing tub—of course you have—lay your plants carefully on their sides in it, over it stretch a towel previously wet, and wrung out; mind there are no holes in it. A bit of glazed calico lining would be better. Make, however, a tiny opening in one corner just big enough for the stalk of a pipe, then enlist the services of your husband, let him fill a good long pipe—a Churchwarden will be best—then light it in the usual way, cover the bowl of the pipe with three or four folds of an old duster or pocket handkerchief, and then let him blow through the same. I know he'll tell you he has got at the wrong end of the pipe, but tell him to blow away, and the green flies lying dead at the bottom of the tub after the operation is over, will be pretty good proof that for once in a way he was at the right end of it, however much he may have thought to the contrary. Two things I must mention as important ingredients in insuring success—first, the plants should be thoroughly dry as regards their leaves—wet repels smoke; and secondly, the pipe stalk should reach the bottom of the tub—smoke prefers to ascend rather than descend. The difficulty which usually attends fumigating, as it is called, is the reason why I have felt obliged to give this detailed description of a process which I have adopted myself with success. The tendency of all plants grown in a window is to get what we call "leggy." This can only be prevented by cutting down, which I alluded to in speaking of repotting geraniums after their bloom is over, but it may further be materially prevented by pinching out the points of the shoots when they are making their young growth preparatory to flowering. Of course some discretion must be used in this operation, else you may get a very bushy plant without any bloom; and as a guide I would say pinch out the growing points of the shoots that have been made after the cutting back process has been performed; once will be sufficient. Staking and supporting the shoots I must leave to the ingenuity of each cultivator.

HANGING PLANTS.

I have hitherto alluded only to plants grown on the window ledge; but what looks more lovely than a plant suspended from a small rustic basket in the centre of the upper part of the window? It interferes with nothing and nothing interferes with it; there's an element of beauty in that simple fact. Plants, which have slender branches, which naturally hang down, are at home in this situation. The "Mother of Thousands"—the "Wandering Jew" with its pretty marked leaves—the "Lobelias," and some of the trailing "Campanulas or Bell Flowers"—the well-named "Rat-tailed Cactus," and the so-called "Ice Plants," are all more at home when suspended than when grown in any other position, unless it may be when placed on brackets at each side of the window, where they have a very charming appearance. I would suggest that the suspended basket or flower-pot should be supported by a piece of cord passed through a small pulley, by which means it will be easily lowered down for the purpose of watering, and also during nights, for reasons which I before gave, and which are specially applicable to such plants as these.

OTHER PLANTS FOR WINDOW CULTURE.

It remains only for me to say a few words as to what other plants are adapted for window culture. In doing this I would address my remarks not only to the artisan or cottager, but to all possessors of a garden with its conservatory and greenhouses. As the latter stroll leisurely through their more or less extensive establishments, and derive that pure enjoyment which the contemplation of nature's handiwork is capable of giving, is it asking too much if they are entreated to assist, by something more than a subscription or a donation of money, in furthering the objects of the window gardening movement?—a movement the aim of which is to foster and encourage a taste that cannot fail to elevate the moral character of those in whom it is once engrafted. No one who has been brought into contact with the persons who cultivate plants in their windows, and who has had the opportunity which those interested in this movement have had, of appreciating the intense affection with which plants are cherished by their owners, but must feel it a pleasure and a privilege to aid in the development and culture of that pure and healthy enjoyment which springs from the love of flowers.

Let me now briefly point out more directly how those who possess the means have the power to assist. A few years ago, and for three successive seasons, an important part of the funds of the Hull Window

Garden Society was devoted to the distribution of those plants which had done duty, during the summer and autumn, in the flower gardens in and adjacent to Hull. These plants were carefully potted and distributed, but as a general rule they were not given until after the frost had not only tarnished their beauty but seriously affected their vitality. Can the result be considered satisfactory, when out of every four plants so obtained and distributed, perhaps but one lived to present its thank offering of flowers, in return for the care and attention bestowed on the whole four through a long winter? In many instances not even one survived. The suggestion that I would venture to offer then is this: that those who have facilities would ask their gardeners to prepare a few plants specially for distribution (I will name the most desirable plants presently), and grow them in what are known as four-inch pots. Plants thus grown, and well matured in the autumn with free exposure to the sun, would be so valuable for window culture that, judging by my own experience, I would rather have one plant thus prepared than half-a-dozen of the plants taken up out of the flower garden. Does your gardener object to aid in this good work, on the plea that it involves for him extra labour! I trust not; for were it so, I should blush for the honour of the profession to which I belong. No! the lover of plants, if he be a true lover, will rise superior to a narrow-minded objection such as this, and will be only too ready to assist, by all possible means, all those who have a love for flowers within them, and not only that, but to call that love into active existence where, from want of opportunity, it has hitherto lain torpid and undeveloped. There is yet ample time before the autumn, and I feel sure the appeal made will not be made in vain.

A word now to the recipients. While rejoicing in the success which will attend the distribution of plants such as I describe, let them remember the feeling with which I have asked the donors to contribute, and let them reciprocate that feeling. Be not unthankful to those who have placed you in a position to appreciate and admire more fully than you have hitherto done the glorious works of the Almighty; and rely on it plants given and received in this kindly communion of feeling will furnish many a useful and pleasant page in your life's history.

It remains but to enumerate such plants as are best adapted for window culture. I have already named those which, by their mode of growth, are suitable for suspended baskets; to these I would only add *Isolepis gracilis*, *Gazania*, and *Ivy-leaved Geraniums*, and *Ivy* itself. The others are as follows:—*Pelargoniums*, scarlet and other varieties, variegated, golden, and silver; *Petunias*, *Fuchsias*, *Cupneas*, *Echeverias*, *Aloes*, *Cacti*, *Vallota purpurea* (*Scarboro' Lily*), *Pteris serrulata*, *Hydrangeas*, *Plectranthas* (*nettle-leaved Geranium*), *Chinese Primrose*, *Calceolarias*, and *Cinerarias*.

GARDENING IN BELGIUM.

ON my first visit to Belgium in the spring, I was much struck with the universal love of flowers and window gardens which is noticeable there. The flowers in the markets are cheap and abundant. The railway journey through orchards in full blossom, bright green fields and patches of yellow colza, was refreshing; and the quiet, peaceful look of the Bruges streets was rendered still pleasanter by groups of gay flowers in most of the low narrow windows. A window of a quaint shape had a light blue-green frame and embroidered muslin curtains, a blind half-drawn down of thin embroidered muslin, with another blind to draw over it just appearing, and made of green and white striped stuff with a fringe, of striped holland, all as clean as possible, and on the window seat two or three azaleas, a small palm, and two glass pots with bright green rye grass grown in cotton wool. The grass looked very fresh and spring-like, and relieved the bright colours of the azaleas. The best houses had splendid banks of flowers raised within their windows; arums and azaleas were the favourites, and there were small shrubs of *laurustinus* trained into standards and covered with blossom. These had a very good effect. In the street leading to our hotel was an entrance to a brewery, but it looked more like an entrance to something between a conservatory and a museum. Great pots of flowers and ferns stood all round, rich masses of colour; numbers of stuffed birds, mostly white ones, were perched about above them; a small aquarium and two or three cages of live canaries and waxbills stood amongst the flowers. The chemists at Bruges appeared to amuse themselves with growing rye grass. I saw one or two chemist's shops with little else in the windows besides this, and some pots of flowers. Yellow wallflowers (double) were favourites, and beautiful spiraeas and mignonettes—a considerably prettier sight, if not so professional, than the red and blue jars in our shops at home. We wandered all about the smaller streets; and in the windows of the poorest-looking houses, and smallest, most miscellaneous shops, we noticed flowers. Forget-me-nots were sometimes to be seen grown in what looked like deep dishes in the window. The canals at Bruges are some of its pleasantest characteristics, the quaint mediæval houses coming straight down into the water, or having little gardens with high walls, and poplars just coming into that rich gold colour which the early leaves show. The trees come in just at all the right picturesque

corners, among red-tiled roofs, and lie reflected in the smooth canal. Lilacs were just in blossom, and every little corner by the low arched bridges that had collected a little mould had a group of iris leaves cropping up into a brilliant bit of green to enliven the old grey walls. I went in to only one garden. From the top of the helfry at Bruges, my eye fell upon a little enclosed and cultivated strip in the midst of the city, and in the course of the day, while visiting l'Hôpital de St. Jean, I recognised the trim little garden as belonging to it, as having an array of beautiful standard bay trees in tubs. We afterwards saw carts full of similar bay trees going through Bruges, and on our way to Ghent passed our friends waiting in their railway truck. Evidently Bruges is expert at their manufacture; they looked very much like orange trees, and were very effective. At Ghent we found the same love of flowers, but not so much among the shops and small houses. The best houses had beautiful bouquets laid out on the cushions of the window seats, and sometimes real flower shows piled up inside the windows.

THE FLOWER MARKET.

Sunday morning brought its treat of flowers to all in Ghent. The first thing I heard when I woke was our maid telling me "the flower market is begun; we should get up and see it." L'Hôtel Royale looks out on the Place d'Armes, a fine open square, surrounded entirely with lime trees. I came into our sitting-room; the tall windows into our balcony were open. Summer seemed suddenly to have come upon us; outside the lime trees rustled, the sun shone, and a hum and tramp of people sounded happily beneath us. There seemed to be very little real business, so as to make one think the Sunday disregarded, but a general innocent enjoyment of the little hand trucks full of roots, pots of flowers, and trays of seeds. The trucks kept in a line under the trees all round the square. The buyers or admirers loitered on each side of them in a holiday sort of way. In the middle of the square children in blue pinafores played, and their elders strolled up and down. We descended into the midst of this pretty flower market to try and get a bouquet. On the staircase I found two or three chambermaids with a great bunch of forget-me-nots from the market. They stopped me to see them, and insisted on my accepting half the bunch, telling me the name in Flemish. In the market were the nice clean market women in Sunday caps, and men in blue blouses. The language was a difficulty. I saw a nice little collection of alpine plants, sedums, and echeverias. I purchased a pretty dark-red plant I had not seen before, that grew up on its stalk like a miniature palm. My Flemish flower boy called it an "echéveria," and a variegated sedum he called "sempervivum." Sempervivum californicum was there, and a good variety of little alpinas. One very favourite plant is an ox-eye daisy, grown in nice little round patches, with long stems, and blossoms standing out all over it. There were numbers of these plants on the Ghent window seats. There were not many bouquets in the market, but the prettiest things were the hanging baskets. There were no flowers in them, but beautiful luxuriant grasses, and the healthiest young creepers I ever saw. Some were arranged with great taste in large shallow cups of red pottery, and the trailing leaves and tendrils of various kinds and shades of bright green made a charming piece of colouring. These latter only cost a franc and a half, and looked well established and healthy. We longed to carry one off with us, but they would have been difficult to manage during our journey; they seemed immensely popular, and were sold off in no time. Great pots of basil were very much the fashion, small palms, white heaths, and numbers of little rose bushes. The hard working dogs lay under the little carts which the poor creatures pull so valiantly, but look out of breath, and make one feel very much for their poor soft feet on these roughly-paved streets. Wallflowers are cultivated very much in pots, particularly yellow ones and the purple kinds, which are grown to a considerable height.

I saw a pretty specimen of gardening at the old Abbey of St. Baron. We drove to see the famous ruins, which are all in a small space, inclosing with arches and ruined walls a little plot of ground. An old man took us in and explained the antiquities, but after a little survey we began to notice the care with which everything was kept. A great plant of acanthus grew in a picturesque corner against half-decayed mouldings and crumbling stones, and a fine bush of rhubarb (grown here for ornament). The little plot of ground had been a dismal wilderness when our friend came to take charge of the ruins, but in the intervals of showing them he had made a charming flower and kitchen garden out of the space they inclosed. His fruit trees were in blossom, and added very much to the appearance of the Abbey, and his neat borders of pink daisies did not take from its picturesqueness. The old walls themselves were gilded up to the highest stones with yellow wallflowers.—*M. A. D.*

Ar-Nut.—This is the *Bunium bulbocastanum*, a root which has a great variety of names, Hawk-nut, Kipper-nut, Pig-nut, Earth-nut, and Ground-nut, besides the Scotch name, properly written, I believe, Arnot. It is called in Burgundy Arnotta, whence probably the Scotch name. It has also the Latin names of *Agriocastanum*, *Nucula terrestris*, and *Bulbocastanum*. The Germans call it Erdnuss. It is found almost everywhere, in woods and grassy places; and is known by its slender stem, leaves like those of wild parsley, with white flowers at the top. It is not easy, however, to secure the root, as that part of the stem in the ground is very slender, and liable to break off, leaving the digger but a poor chance of finding the root, which is pretty deep in the earth, and the clue to which is lost when the stem breaks. The nut is nearly as large as a nutmeg, and has a brown coating, which easily peels off and encloses a yellowish nut, the flavour of which is rather sweet, but at the same time pungent, and not very pleasant.—*Notes and Queries.*

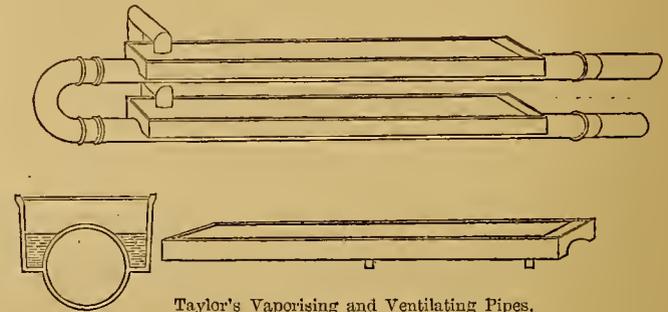

GARDEN STRUCTURES.

MESSRS. HOWITT'S PRIZE HOUSE.

WE purpose from time to time illustrating garden structures that present any novel features, not necessarily to recommend them as the best of their kind, but simply because, in the interest of knowledge, it is desirable that the horticultural public should know something of the aspect and peculiarities of such structures.

Our illustrations this week show the elevation and details of Messrs. Howitt's house, drawn by our special artist at the Birmingham show.

The house shown at Birmingham was thirty feet long by seventeen feet wide, heated with Taylor's patent combined warming, ventilating, and vapourising pipes. The house is constructed on a patent system. The rib, or roof truss, is

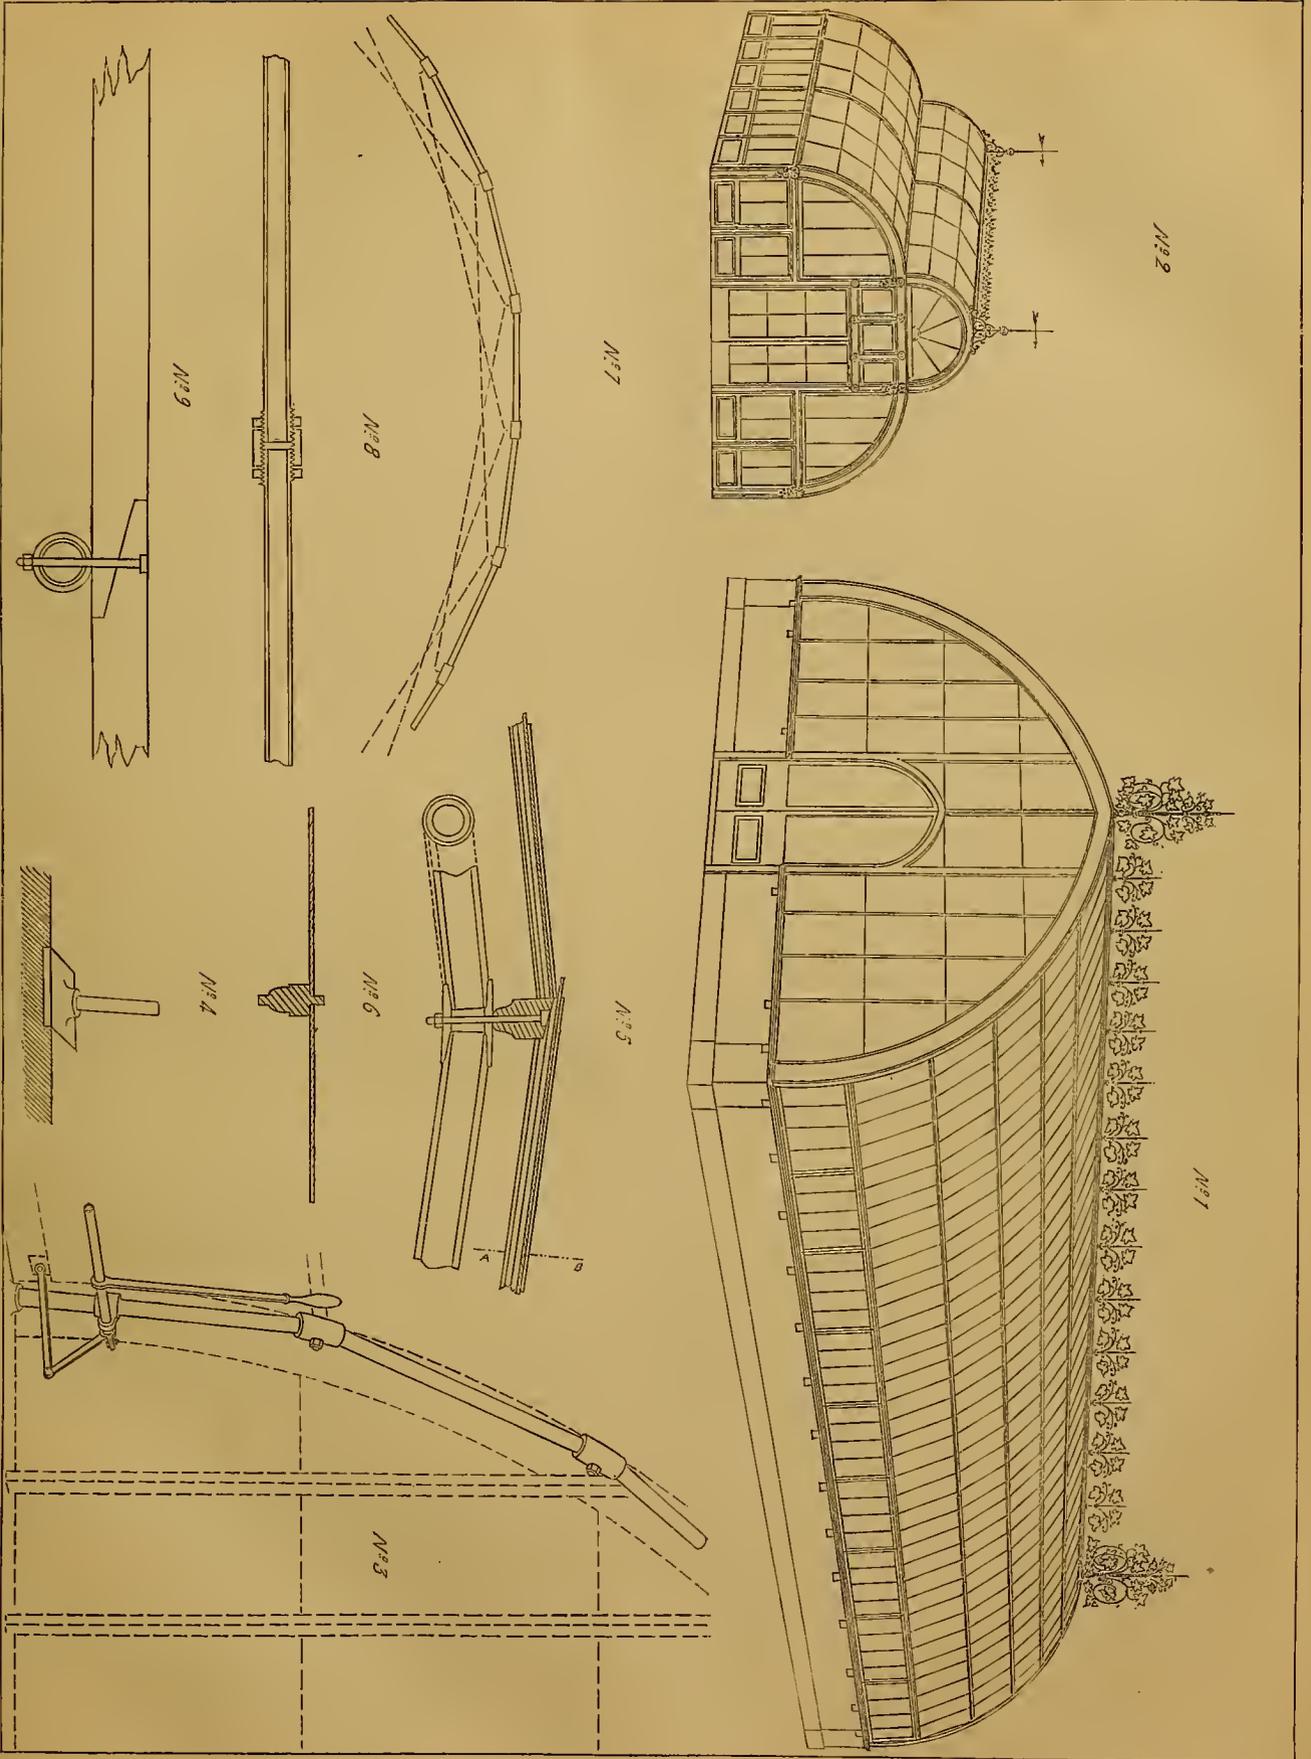

Taylor's Vaporising and Ventilating Pipes.

formed of twelve (more or less according to the size of the house) lengths of straight wrought-iron pipe, $1\frac{1}{2}$ inch in diameter (according to span of roof), jointed together by means of very strong wrought-iron sockets, bored at an angle requisite to give the necessary curve to the roof. This rib or truss being free from outward thrust requires no cross tie-rods, so that an uninterrupted headway is preserved. The inventors claim in their notes handed to the judges, "that the extreme lightness and great strength of this rib specially adapt it for use in the construction of horticultural buildings, where symmetry of form and beauty of design, combined with a minimum amount of sunshade, are of paramount importance. They have constructed this house with part iron and part wood sashes, so that the public may individually choose which they would prefer. The sections of tubular, rib, or roof truss are socketed, not screwed together, and are made so that any pipe will fit any socket, and all the other parts of the house are screwed and bolted together, so that it is claimed as a great advantage that the house may be taken to pieces and re-erected at pleasure. The glazing is so arranged that any condensed water in the inner side of the uppermost series of panes percolates on to the outer side of the next series of panes, and so on to the bottom, thus avoiding all 'drip' into the house. Another advantage is that the expense of glazing a house of this kind is no greater than that of a rectilinear structure, straight glass alone being used. They propose to use in their houses Taylor's patent combined, warming, ventilating, and vapourising pipes.

"The special feature of this patent is the introduction of the outer air through a partially closed chamber or trough, on the top of the hot-water pipes; when this chamber is half filled with water, a pure, genial, and warm climate is produced. A constant change of air is obtained without opening the sashes. The exit of the air takes place at the top, where a shaft or aperture is made for the purpose."

THE PRIZE HOthouse AT BIRMINGHAM.

OUR FRUIT CROPS.

SOUTH EASTERN DIVISION.

Cliveden, near Maidenhead, Berkshire.—All outdoor crops in this neighbourhood are a failure through late spring frosts. To this statement there is, as far as I know, no exception.—J. FLEMING.

Chevening Place, Sevenoaks, Kent.—Apples are a failure, as are also Apricots. Peaches half a crop; Pears good; Currants half a crop; Gooseberries good; Strawberries and Raspberries half a crop; Plums good; Cherries half a crop; Walnuts a failure; Filberts half a crop.—D. COE.

Eridge Castle, Tunbridge Wells, Kent.—Of Apricots we have none. Peaches half a crop; best where sheltered. Pears on walls, a fine crop. Plums, a few on walls; standards, none. Apples, very scarce; King of the Pippins, Winter Queening, and Keswick Codlin, pretty good. Cherries, not quite a full crop. Strawberries, fine. Raspberries, excellent. Gooseberries, not a full crop. Currants, half a crop. Nuts, scarce. Figs, a full crop. There was a capital show of blossom, but late spring frosts did the mischief.—J. RUSK.

Portnal Park, Staines, Surrey.—Outdoor fruits have suffered severely from spring frosts. Peach and Nectarine trees in some places are very much injured. Late Pears are a failure, but of early sorts I have a good crop. Apples on standards very thin, and on espaliers I have none. Plums very thin, much under average. Of Figs I have a fair sprinkling. Cherries, excellent; and Strawberries, Gooseberries, and Raspberries I have in abundance. Red and white Currants thin, black a heavy crop. Orchards in this neighbourhood, with few exceptions, have failed.—THOS. MAY.

Broadlands, Romsey, Hampshire.—I have a very unsatisfactory return to make for myself and neighbourhood. Strawberries, however, have been good; Pears an average crop; Apricots none; Peaches, none in most places; a fair crop of late ones here; no early ones; Gooseberries and Black Currants, below average; Red and White Currants scarcely any; Raspberries an average crop; Apples, a few Hawthornedens and "Profits" in some places; in others none at all; wild Blackberries are a good crop, and of these we intend to make up our quantum of preserved fruits for winter use.—T. DAWSON.

Albury Park, Guildford, Surrey.—With us Apricots are a complete failure; Apples very few, very much blighted; Pears half a crop, very much deformed and small; Plums very few on walls, none on standards; Cherries very few, trees much blighted; Figs half a crop, trees much improved since hot weather set in; Peaches and Nectarines very few, trees badly infested with aphides; Grapes good, but late; Gooseberries little more than half a crop, but very good; Currants of all sorts very few, scarcely any in this neighbourhood; Raspberries, a very good crop; best we have had for years; Strawberries half a crop, bloom very much cut by late frosts; Filberts and Walnuts both a total failure.—WILLIAM KEMP.

Royal Gardens, Frogmore, Windsor, Berks.—The following is the state of outdoor fruit crops in these gardens, viz.:—Apricots very thin, many trees quite failed. Apples, generally a light crop, with the exception of a few free-bearing varieties, such as Scarlet Russet, Pomona, Frogmore Prolific, Downton Nonpareil, and Small's Admirable. Cherries, generally thin, even including Morellos. Pears, a moderate crop, but they promise to be of good quality. Strawberries, an average crop, but soon over. Peaches, a good crop and looking well. Nectarines also a good crop. Of small fruit, Raspberries are a good crop. Currants, both black and red, are very light; fruit small and thin in the bunch. Filberts, a light crop. Walnuts nearly a total failure. The foregoing will also apply to the neighbourhood of Windsor generally, with the exception of small fruits; of these in spots there are good crops, especially of Currants and Gooseberries, and in a few places the Peach and Nectarine crop is very thin. Altogether the outdoor fruit crop is very light, and much below the average.—J. POWELL.

Coleshill, Highworth, Berks.—Apples, almost a total failure; trees much blighted, many of them past recovery. Apricots also a total failure; while carrying an unusually heavy crop last autumn the trees were attacked by mildew, which injured them so seriously that we had no bloom at all this spring; the trees still look sickly, but are improving since the hot weather set in. Cherries promised to be an immense crop, but frost, during the time the trees were in flower, injured them seriously, and again, at the beginning of June, the frost pinched them hard; a large portion dropped off, and half of those that remained were not fit for table, owing to frost-bite; the result is a very thin crop of inferior fruit. This also applies to early kinds, such as May Duke, &c.; Morellos fine, and a fair crop. Currants of all kinds, red, white, and black, good. Mulberries promising. Gooseberries, not quite so plentiful as usual; fruit very

fine. Peaches, a thin crop, but they promise to be of fine size; trees which have looked sickly are improving under the influence of late hot sunshine. The same remarks apply also to Nectarines, which are, perhaps, a little thinner than the Peaches. Pears, consisting of Jargonelle, Bon Chrétien, and other early kinds, are a good crop, but fine autumn and winter sorts are very thin, and many of them are so much injured by late frosts that they will, I fear, fall off before they ripen. Trees, too, look sickly; they are evidently suffering from the peculiar weather which we had last summer. Of Plums, with the exception of Greengages, we have literally none, and the trees are blighted and half dead. Two years ago fine plums were sold in our neighbourhood at 2s. per bushel. Raspberries were much damaged by frost when in flower; therefore thin and poor. Strawberries, with the exception of Keen's seedling, which suffered from frost more than other kinds, have been good and fine. Walnuts, none; other Nuts, partial.—H. ECKFORD.

SOUTH MIDLAND DIVISION.

Ramsay Abbey, Huntingdonshire.—Generally speaking, stone fruits, such as Peaches, Nectarines, Plums, Apricots, and Cherries are very thin. Several young trees, three or four years planted, that have never been exhausted by over-cropping are, however, carrying a fair crop. Apricot trees are clean and in splendid health, but Peaches and Nectarines have been very much infested with black fly, and have required unceasing attention to keep them clean. Looking at the difference between the crop in the orchard house and the open wall, one is apt to sigh for the time when a supply of all our choice stone fruits may be grown under glass. In regard to Apples, both on dwarfs, in the kitchen garden, and standards in the orchards, many trees are carrying a full crop. Some few have, however, scarcely recovered from the exhausting effects of the heavy crops which they bore two years ago, and are consequently nearly bare. Pears, on the whole, are a fair average crop on walls. Bush fruits and Strawberries have been plentiful and good in spite of the spring frosts. Alpine Strawberries are very full of fruit, and will continue bearing till frost cuts them off. Walnuts and Filberts are very thin. Outdoor Grapes are plentiful, and generally free from mildew, but will in all probability be late in ripening.—E. HOBDAV.

Moorpark, Rickmansworth, Hertfordshire.—Outdoor fruit in this neighbourhood is very much under average, but in some localities may be found a fair sprinkling of certain varieties of Apples; with us the Keswick Codlin and Norfolk Beefing—two good old and useful sorts—are a fair crop; others very thin. Ribston Pippin, Margil, and some of our approved dessert sorts, although having set well, dropped off at a certain stage of their development, caused, I have no doubt, by the cold rains and sharp frosts which we experienced when the trees were in flower; also, after the Apple and Pear crop was set, Pears dropped their fruit, and, with the exception of a few sorts on south walls, such as Marie Louise, Citron des Carmes, &c., it may be said Pears are a failure. Plums and Cherries, which at one time promised to be a heavy crop, ultimately dropped an immense quantity of their fruit in an early stage of its development, so that Plums are not an average crop, and Morello Cherries, usually heavily laden with fruit in former seasons, are this year a lighter crop than I ever remember to have seen them. A new enemy set on our May Duke and other dessert sorts this year, but left untouched some Morellos I had on a south wall. I mean snails, which cleared heavily-laden trees of good flavoured Cherries in a night or two. Apricots, Peaches, and Nectarines, out of doors, are a complete failure here. Out of door Strawberries with us have been a "sight." We are still gathering daily, which, with forced fruit, makes our Strawberry season a long one. Crops of red and black Currants are heavy and good. Gooseberries a fair crop. Walnuts, Cobnuts, and Filberts poor.—D. CUNNINGHAM.

WEST MIDLAND DIVISION.

Alton Towers, Cheadle, Staffordshire.—Strawberries, abundant, but they have suffered much from storms; Gooseberries, half a crop; Currants, thin, destroyed by frost; Pears, very thin; Apples, half a crop; Peaches, outside, excellent in some places; Apricots, none; Cherries, plentiful.—T. RABONE.

Compton Verney, Stratford-on-Avon, Warwickshire.—Apples, a failure; Pears, an average crop; Peaches and Nectarine, the same; Apricots, half a crop; Plums, under average; Morello Cherries, half a crop; Figs, a crop; Walnuts, a few; Strawberries, under average; Raspberries, a good crop; Gooseberries, under average; Currants, poor. The above is the state of the crops in the garden here, and may be taken as a fair representation of the neighbourhood.—G. CRADDOCK.

Keele Hall, Newcastle, Staffordshire.—In this district there is no fruit on Peaches and Nectarines on open walls, and the same may be said of Apricots; Cherries, fair crop; Raspberries, very good; Strawberries, good, but injured by frost in many places; Gooseberries, good; Currants of all sorts, fair. Both these fruits have also been injured by frost in many places. Pears on walls, good; Apples, the greatest failure I ever remember; the trees, too, have suffered so much from caterpillars, that the foliage is very bad.—W. HILL.

Downton Castle, Ludlow, Shropshire.—With us Apples are very scarce; in fact, I shall not have more than a bushel off a very large quantity of trees, and they are much about the same all over Herefordshire. Peaches and Nectarines not so good as usual with me, but still I have a fair crop; in some places, however, about here they have no fruit, and the trees are nearly killed by mildew, gum, and canker. Plums, Apricots, and Cherries not half a crop. Of Pears I have a good crop, both on walls and standards; bush fruit all good, and fine in quality.—WM. LANOON.

Shobden Court, Leominster, Herefordshire.—Of Apricots we have scarcely any, and of Peaches and Nectarines very few; Plums on walls are not an average crop, while on standards there are scarcely any. Of Pears there are very few, and Apples are very scarce in this neighbourhood. The trees bloomed most profusely, but all dropped owing to the long continued cold. Strawberries have been abundant; also Gooseberries and Currants, but late in ripening, as we have had so much rain, with scarcely any sunshine. The last few days have greatly improved the appearance of all kinds of crops.—J. MATTHEWS.

Madresfield Court, Great Malvern, Worcestershire Fruit crops this season are extremely partial, the cold weather of May, and especially the severe frost of the 19th of that month, did much injury to strawberries and bush crops. With me Peaches and Nectarines are very good and clean; Apricots half a crop; Pears and Plums on walls good, on espaliers and pyramids a failure. The earlier kinds of orchard fruit are good; later sorts scarce. Currants and Gooseberries a fair crop here, but by no means generally so. Strawberries, where not injured by frost, have been generally good, but soon over; President and Sir J. Paxton have cropped well, but the most valuable Strawberry I grow is one named Oxonian. This is only just coming into use (July 26th), and will last three to four weeks; a north border suits it better than any other aspect. Nuts, Filberts, and Walnuts quite a failure here.—WILLIAM COX.

Tortworth Court, Wotton-under-Edge, Gloucestershire.—Crops in general have not been so light for many years past as they are this season. Peaches, Apricots, and Plums are almost a complete failure; on Plums, in some few instances where trained against walls, there is a sprinkling. Apples are so scarce, that we shall not, in a three-acre orchard, be able to harvest above two bushels, the varieties being confined principally to the Codlin section; not only did the late frosts destroy the blossom, but the foliage as well, which is just beginning to recover; but I fear the young wood will not ripen properly. The Pear crop is not quite a failure, but it is nearly so. Standard Cherries are a failure. On walls we have one-third of a crop, with the exception of the Morello, which is abundant. Of Raspberries we have half a crop, but the fruit is small. Of black and red Currants there is about half a crop. Figs are a failure; Gooseberries, abundant; Strawberries, one-fourth of a crop; Nuts, abundant. Many in this neighbourhood have lost both Apricot and Peach trees. Farm orchards are barren, therefore Cider will be scarce.—ALEXANDER CRAMB.

Packington Hall, Coventry.—Our Apricots are about half a crop, which is by no means general, as in most gardens round here there are none. Peaches and Nectarines, with me, a quarter of a crop; in most gardens, however, there are none. With the exception of Royal George and Grosse Mignonne Peaches, my other Peach and Nectarine trees are in fine health, but these two sorts are much infested with mildew, which shows that they are of a more tender constitution than most other varieties used for outdoor work; this, too, is not the first time that I have watched their tendency to become diseased when the season has happened to be ungenial. Plums on west aspect walls, a fine crop; on east aspect or north, none; which may be accounted for by the fact that east and north aspects do not receive the same amount of sun as a west wall. In very few gardens, however, round here are there any Plums. Pears, on all aspects on walls and standards, with me are a fine crop; but in many other gardens they are very thin. Apples, with rare exceptions, are a total failure, both in orchards and gardens. Cherries, Quinces, Medlars, Filberts, and Walnuts, are all bad; even Morellos are mostly a failure. Here all bush fruits, such as Currants, black, white, and red, are very thin, as well as Gooseberries and Raspberries; Currants on a north wall are, however, fine. Straw-

berries are a failure, and such is the rule in this district, caused undoubtedly by the frosts which we had on the nights 26th, 27th, and 28th of May, when the Apples were in full flower; the Pears, being more forward and covered with leaves, especially on walls, escaped. Blight is everywhere abundant, caused doubtless by cold and wet in May.—J. G. TEMPLE.

NORTH MIDLAND DIVISION.

Berry Hill, Mansfield, Notts.—Apricots, a failure, plenty of bloom, but it was entirely cut off by spring frosts; Peaches, a very poor crop; Plums, a good crop, especially on walls; Figs, none grown outside; Cherries, a good crop; Apples, a fair crop; Pears, a moderate crop (there was abundance of bloom, but it got entirely destroyed by frost); Gooseberries, a good crop; Currants, abundant; Strawberries, very good, but flavour poor owing to the heavy rains; Raspberries, very good; Damsons, quite a failure; Walnuts, very few; Filberts, a poor crop.—S. A. WOODS.

Sudbrooke Holme, Lincolnshire.—Apples, a thin crop, Pears, half a crop, Plums, a fair crop, Apricots and Peaches, very thin. All bush fruit and Strawberries, a good crop, but the Strawberries have been much spoiled by heavy rains. Trees very healthy and free from blight. In this neighbourhood Apple orchards are producing a fair crop, where sheltered from north-east winds. Plums and other fruits partial. Cherries are a fair crop, but spoiled by the rains. The loss of our fruit crops must be attributed to the wood being badly ripened last autumn, and to the low temperature this spring.—GEORGE MCBRY.

Exton Park, Oakham, Rutland.—Apple and Pear trees never looked more promising than they did this spring; but a cold May, with much rain and frosty nights succeeded by a few hours, very hot sunshine, seemed to burn them all black. The failure, I think, is general in this neighbourhood. Apples and Pears are very scarce; Peaches and Apricots are a failure; of Nectarines we have a few; Figs a small crop; Filberts and Quinces, none; Walnuts, thin crop; Small fruits, good; Strawberries, very fine and large; President, Lucas, Sir C. Napier, and Elton Pine have been the best here. Cherries, a grand crop. Morellos are now nearly as large as good-sized Gooseberries.—J. SMITH.

Coleorton Hall, Ashby-de-la-Zouch, Leicestershire.—In spring, I never saw such a prospect of a great crop of fruit. But the severe frosts in April cut off even the Apple buds long before they could expand. At present our crops stand as follows:—Apricots none; Apples scarcely any; Morello Cherries on walls, plentiful; all other sorts a failure; Plums on walls half a crop; on standards a complete failure; Peaches and Nectarines very few, next to none; Pears on walls half a crop; on standards scarcely any; Figs very few; Currants of all kinds a fair crop; Gooseberries half a crop; Raspberries, a good crop and fine; Strawberries, President and Wonderful pretty good; very few of other kinds; Walnuts and Filberts a failure. The failure of fruit crops in our immediate neighbourhood is general.—M. HENDERSON.

Osmaston Manor, Derby.—The following remarks concerning pears apply to trees trained on walls with east, west, and south aspects: Althorp Crassane and Beurré d'Areberg, fine crops; Williams's Bon Chrétien, Doyenné d'Été, Easter Beurré and Beurré Diel, good crops; Ne Plus Meuris, Louise Bonne of Jersey, Délices d'Hardenpont, and Summer Frauc Réal, moderate crops; Marie Louise and Jargonelle, thin; Chaumontelle, poor, and the same may be said of Passe Colmar, Beurré Rance, Thompson's, Glou Morçean, and Knight's Monarch. Beurré Rance has never missed before during ten years. Pears altogether are very irregular, some trees being loaded, whilst others close at hand have little or no fruit on them. Gooseberries abundant, only slightly hurt by spring frosts; Red Currants, moderate; Black Currants, scarcely any; Raspberries, a good crop; Strawberries, also a good crop, but much damaged by rain; Plums and Apricots, very scarce; Cherries, a fair crop, but a good deal cracked owing to the long-continued wet; Apples, a poor crop (none on tall standards). Peaches and Nectarines are not grown out of doors here.—F. HARRISON.

Bloxholm Hall, Sleaford, Lincolnshire.—Apples in this neighbourhood are a very deficient crop; trees much blighted by late spring frosts; Pears on walls a fair crop, but on standards, in exposed parts, very deficient; Plums on standards a complete failure, a fair sprinkling on walls; Apricots on walls a fair crop, where protected, but where unprotected, on the same wall and situation, they have been destroyed by late spring frosts; Strawberries, an excellent crop, and very fine in quality, but their season was of short duration; owing to constant drenching rains when in full bearing, they rotted by wholesale on the ground; Cherries on walls a fair crop, on standards a failure; many of the Cherries have cracked, owing to the excessive rainfall in July; Peaches and Nectarines poor, trees,

much blighted in many parts; Figs a fair crop; Raspberries abundant, and of excellent quality; Gooseberries very good; Red Currants under average, bushes much blighted; Black Currants also under average, but good in quality; White Currants a fair crop of fine fruit; Walnuts promised to be good early in the season, but they have fallen off during the summer, and now only a very poor crop will be gathered; Filberts also very poor. Altogether outdoor fruits are not encouraging, although we had an abundance of strong and healthy bloom. Fruit trees generally were early in flower, owing to the mildness of the winter, but they suffered greatly from severe spring frosts.—DAVID LUMSDEN.

SOUTH-WESTERN DIVISION.

Sherborne Castle, Dorset.—Fruit crops in this garden and the neighbourhood run nearly as follows:—Apples almost a failure; Apricots quite a failure; Cherries a very middling crop; Red and White Currants very scarce; Black Currants plentiful; Figs a moderate crop; Gooseberries, in most parts, very plentiful; Medlars very few; Mulberries good; Nuts of all sorts very scarce; Peaches and Nectarines also very scarce; Pears, a sprinkling on walls, very few on pyramids; Plums almost a complete failure; Quinces a few; Raspberries a very fair crop; Strawberries plentiful.—W. G. PRAGNELL.

Ennys, Penryn, Cornwall.—Apple orchards gave early promise of a good crop. The blossom was not so thick as it sometimes has been, but it was strong and perfect; yet the crop was doomed. Several degrees of frost destroyed all hope. There is, however, a sprinkling in some few sheltered places, but no crop anywhere, as far as I can learn. Of Pears there is a better report, especially of early and autumn kinds. Peaches and Nectarines are far below the average; some places not half a crop, others much less than that. Plums a poor crop. Raspberries plentiful. Bush fruit the poorest crop known for years past. Strawberries, good crops. Cherries below the average.—HENRY MILLS.

Nettlecombe, Taunton, Somersetshire.—The following is the state of the fruit crop at Nettlecombe, and, I believe, it is much the same in this neighbourhood generally:—Of Apricots we have scarcely any; Peaches and Nectarines none, trees much injured by frost in May, accompanied by cold winds, rain, hail, and snow. Cherries about half a crop. Pears about two-thirds of an average. Apples, scarcely any; trees much injured. Plums none. Medlars none; trees much injured. White and Red Currants, scarcely any. Black Currants, average crop. Gooseberries, very plentiful. Raspberries, two-thirds of a crop. Strawberries, about half of an average crop, but small. Quinces, none. Walnuts, very few, the male catkins having been killed by frost before the pollen was formed. Filberts, none, owing to the same cause. Kent Cob Nuts, very few. Figs, about half a crop. The destruction of our fruit crops is doubtless owing to the trees having been excited by the mildness of the weather throughout January, February, and the beginning of March; then from about the twentieth of March we had almost continually cold rains and high winds, with heavy hail and snowstorms, and but very little sunshine up to the second week of June. I am, therefore, rather surprised that we have any fruit at all.—CHARLES ELWORTHY.

NORTH-WESTERN DIVISION.

Doddington Park, Nantwich, Cheshire.—The frost on the 19th and 20th of May destroyed most of our bush fruits; Apples and Plums are a complete failure; wall fruits thin; Apricots, none. Pears on walls, very good; Raspberries and Strawberries, good.—D. F. SELWAY.

Worsley Hall, Manchester.—Owing to the garden here being situated on the borders of Chat Moss, spring frosts have almost ruined our outdoor fruit crops. So lately as June 7th we had a sharp frost, leaving the eaves of the hothouses covered with ice and the grass quite white with hoar frost. Standard Plum trees have suffered most, being in some cases quite denuded of foliage. We have no Plums at all. Apples bloomed gloriously; but they, too, had to succumb to the relentless frost-laden north wind. Small fruits, with the exception of Black Currants, which are all but a failure, about half a crop. A few young Peach trees, all we have out of doors, have been almost killed, all their first growth being cut off. Pears, a very thin crop, though not so bad as Apples. Jargonelles on the whole are carrying fair crops. Strawberries were a good crop, but more than half of them have rotted on the plants, owing to the excessive wet weather which we have had. Morello Cherries very good; of other sorts few are grown. Altogether the fruit crops are as unsatisfactory as I have ever known them to be.—W. B. URBORN.

EASTERN DIVISION.

Audley End, Saffron Walden, Essex.—Fruit crops in this neighbourhood are very short indeed. Apples very scarce, in fact, not a quarter of a crop; Pears a few; Plums almost none; Apricots a very few; Peaches and Nectarines very scarce; Cherries a few; Morellos, Gooseberries, and Currants not a quarter of a crop; Figs a middling crop; Strawberries and Raspberries are the only kinds of fruits of which I had a crop. Indeed, this is one of the worst seasons I have ever known for fruit.—GEO. YOUNG.

Cossey Park, Norwich.—Wall fruits, a failure—not one dozen Peaches or Apricots on the trees. The warm weather in February caused the blossoms to open, and they got blighted by the severe frost and snow of March, which also injured Gooseberries and Currants. In Norwich Market these used to fetch about a penny a pint, but this season they have brought 2½d. and even 3d., while good Raspberries realise 4d. a pint. Such high prices were never heard of in Norwich before. Plums on walls are scarce, and there are none on standards. Cherries were a bad crop. I have a sprinkling of Apples and Pears, but many of my neighbours have none; in fact their trees were so blighted by the cold weather in May that it will be long before they recover.—J. WIGHTON.

Hardwicke House, Bury St. Edmunds.—This, on the whole, is a sorry season for fruits. Spring frosts and hailstorms in May wrecked thousands of fair prospects. Now and then, however, good crops of Peaches, Nectarines, Apricots, and Plums, delight our eyes. Crops of Apples and Pears are less rare. For months these seemed to have escaped the weather; the fruit clung to the trees though a good deal bruised, and looked much better than the leaves, so ragged and torn; but presently the fruit stood still, anon it seemed to look sick, faint, and down it dropped. I have seldom seen so many Apples fall prematurely. Still upon the whole we shall probably average one-third of a crop of Apples and half a crop of Pears. The latter are, however, very spotty on pyramids, and even on walls. In many gardens a clean sweep has been made of Currants and Gooseberries. I, however, have had an extraordinary crop of the latter and a fair share of the former. Raspberries and Cherries have likewise been plentiful, the former especially so, the latter more exceptional. Strawberries plentiful and good, though everdone with water.—D. T. FISH.

NORTHERN DIVISION.

Thorpe Perrow, Bedale, Yorkshire.—Apples almost a failure; Apricots, a very partial crop; bush fruits, good generally; Peaches, a moderate crop; summer Pears good, winter sorts partial; Strawberries, good, but mostly spoilt by rain; Nuts, bad.—WILLIAM CULVERWELL.

Alnwick Castle, Northumberland.—Fruit trees here bloomed abundantly, but owing to bad weather while they were in flower, some sorts are all but a failure. Apples are only about half a crop. Pears an average crop, and the trees are clean and healthy. Plums a fair crop, with the exception of Greengages, of which we have few. Strawberries and all other small fruits abundant. Cherries, with the exception of a few May Dukes on an east wall, almost a failure. Peaches and Nectarines very scarce, trees clean and healthy. Apricots an average crop, and trees in good condition. Figs medium crop.—A. INGRAM.

Bretton Park, Wakefield.—All kinds of small fruit are very plentiful here; but all the gardens situated in low, wet, and exposed places have suffered much from the frost on the 19th and 20th of May, and have but a thin crop. Strawberries have been unusually large this season; but a great part of them was spoiled by the heavy rains which we had last week, rotting them before they began to colour. Apples and Pears are rather scarce all round this district; the only kinds of Apples of which there is a full crop are Keswick Codlin, Hawthornden, and Emperor Alexander; trees of the late-keeping sorts have scarcely a fruit on them. Peaches and Apricots are quite a failure; all other stone fruits scarce. Figs look promising. Fruit trees of all kinds have been much infested with insects and mildew.—G. CLIFTON.

Southend, Darlington.—Strawberries have been good, and large quantities gathered, notwithstanding the heavy thunderstorms and rains to which the crop has been exposed. Gooseberries and Currants are a fair crop, and free from fly and honey-dew, from which in some years we suffer to a great extent. Apricots not a full crop; indeed in many gardens they are a failure, and only upon a few trees in some favoured locality have I seen fruit. Plums better, but still a partial crop. In the gardens here some trees are good beyond the average; but many—very many—of our best trees have no fruit on them. What I have just said respecting Plums, may

also be said of Pears and Apples; and close-pruned trees, such as espaliers, bushes, and pyramids, are much worse than standards or orchard trees. Bloom at the proper season there was in abundance, but it did not set well. With us Peaches and Nectarines are not to be depended upon, except under a glass cover, and there the crop is excellent; indeed it never fails.—JOHN RICHARDSON.

Stourton Park, Knaresborough, Yorkshire.—The demand for fruit in the market, and the prices obtained for it there, are very good criterions of the state of the crops. In 1870 crops of all kinds were abundant, and prices were low. Last year the crops of some kinds, such as Peaches, Nectarines, Plums, Cherries, and Apples, were light in this neighbourhood, and prices were in consequence high. This year crops of all kinds of fruit are, in general, very light, though there are some places where some kinds are good. Apricots are very thin in most places; the crops in 1870 were very heavy, so that people did not expect a heavy crop this season. The trees had not much blossom on them this spring, and the little there was, being weak, dropped off without setting. Peaches and Nectarines are in general thin; on trees that made strong wood which did not get well ripened there is very little fruit, but on trees that made weaker growth, which got well matured, there is plenty. On some trees here there is a heavy crop; whilst others have few or none. Some kinds of Plums on walls are good, but on standards and dwarfs the crops are very light. Victoria and Golden Drop are good crops; and Greengage, Jefferson, Goliath, and others are moderate crops in some gardens on walls, but on standards in general the crops are very light; the trees have also suffered much from aphides. Pears are in general a moderate crop. Jargonelles on walls in some places are good, and in others rather light; on standards the crops are in general light; altogether the Pears will be much below an average crop. Apples are everywhere very thin. There was a fine show of blossom, and there was every appearance of a heavy crop until the 19th and 20th of May, when the frosts on these mornings dealt out sad destruction to the Apple crop. The Cockpit, a sort grown much in this neighbourhood, appears to have withstood the frost tolerably well. A large old tree of Early Juneating has also a fine crop. Hawthornden, King of the Pippins, White Astrachan, and some others have a fair sprinkling of fruit, but many others have very few; altogether I consider the Apple crop this season as bad as any we have had for some years. Strawberries have been a fair crop in some places; but in others they appear to have suffered from the weather. Here the crop, with the exception of British Queen, which promised well, but did not set well, was a good one. Bush fruits of all kinds here are a fair crop, but Red Currants and Raspberries are not so good as we have had them. I believe bush fruit in general is rather below the average in this neighbourhood. The prices in the markets are nearly double what they were in 1870, and the quality of the fruit much inferior. Altogether the fruit crops in this neighbourhood are very deficient, and will be a sad loss to the populations of our large towns, whose consumption of fruit is something wonderful, the loss of Apples especially will be much felt. The quantity of foreign fruit that comes into our markets is very great, and helps to keep down the prices, and when our own crops are good, this brings fruit within the reach of working men, but when our own crops are failures, the prices in general rise too high to be within their reach.—M. SAUL.

NOTES AND-QUESTIONS ON THE FRUIT GARDEN.

The Pear Grafted on the Quince.—All cultivators know how difficult it is to make some varieties of the Pear succeed on the Quince. M. Carrière has lately pointed out an easy road to success in this matter, namely: always to operate by cleft-grafting, instead of by budding. By this means, in the case of those varieties which exhibit a reluctance to unite with the stock, the disastrous effects of high winds are avoided, and the union of the scion with the stock is secured sooner and more permanently.

Wash for Fruit Trees.—Last year an experienced fruit-grower, the owner of a fine orchard near Niagara river, western New York, wrote us that, in the care of his trees he had practised one simple method with eminent success. He takes lye from leached ashes, mixes a little grease with it, heats quite warm, and, with a syringe, throws it up into all parts of the trees, branches, and trunk. It will effectually kill all kinds of caterpillars, and all kinds of worms that are either infesting the trees in nests or running over the bark. Trees treated in this manner were exceedingly healthy, beautiful, and vigorous in appearance, possessing a smooth glossy bark, and bore the best apples in the country. The remedy is easy and cheap.—*Horticulturist.*

The Strawberries of Monrepos.—It may not be without interest to strawberry-growers to state that this year, in the celebrated gardens of Monrepos, near Geisenheim, large quantities of strawberries, each 1½ oz. in weight (and some of 4 oz. to 4½ oz.), have been gathered. These giants occur chiefly amongst the following kinds: Ambrosia, la Constante, Duc de Malakoff, Sir Charles Napier, and Wonderful. In all the gardens of Monrepos the strawberry-beds are covered in autumn with short stable-dung, and in spring, after the ground has been stirred up, with a layer of tan. Tan is also employed as a mulching over the roots of fruit trees, in order to prevent the rapid drying up of the soil in the months of June, July, and August, to secure an equable temperature, and to drive away vermin. It appears that the smell of tan is peculiarly offensive to insects.

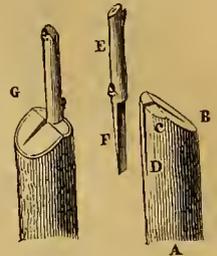

THE PROPAGATOR.

THE ART OF GRAFTING.

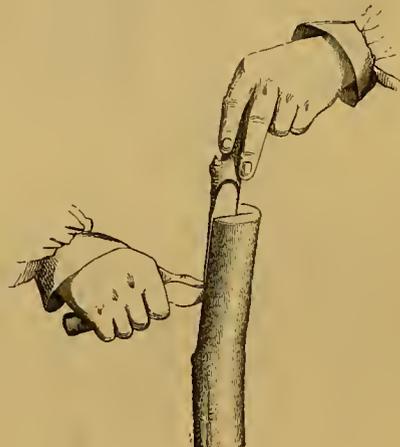

(Continued from p. 26.)

ORDINARY CLEFT-GRAFTING.

WITH A SINGLE SCION.—We have at our disposal a stock (A) of medium size. We cut it obliquely at B, the top (c) of the cut being smoothed horizontally; then inserting the point of the pruning-knife, or the blade of the grafting-knife, we move it gently backwards and forwards, pressing on it moderately, until a vertical cleft (D) is made about the depth of the slanting cut of the scion. The skill of the grafter is displayed in not splitting the stock right across. Care should be taken that the bark and the first albuminum layers of the stock be divided in the same line as the cleft, and with a clean cut; if they should be divided irregularly, no attempt should be made to smooth down or remove the irregularities of the fracture. When the cleft is about two-thirds completed, we take the scion (E) in our other hand and insert it in the upper part of the orifice, pushing it downwards as the incision opens. The implement is withdrawn when the incision has proceeded so far that the scion can be finally lodged in its position by a push of the hand. The sloping cut (F) of the scion is so placed at G that its bark may coincide with that of the stock

Ordinary Cleft-Grafting with a single scion.

Insertion of the Scion in Cleft-grafting.

without projecting or leaving much of a cavity on the inside if possible. If the stock has a thick bark, we should slightly incline the scion inwards in the cleft, so that the layers of bark and albuminum of both stock and scion may inevitably find some point of contact; for the union is effected by the contact of the generative layers of both parts, and not by the external layers of the bark. Mastic is necessary: bandaging not so much so.

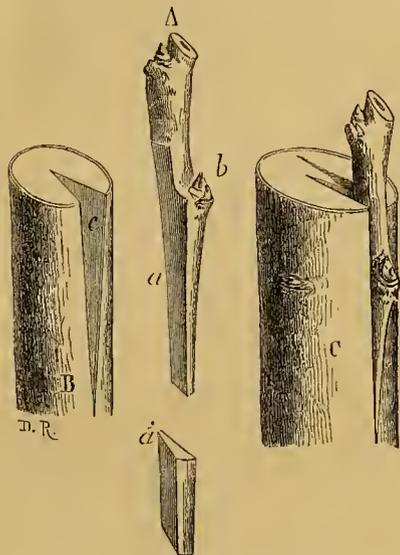

WITH TWO SCIONS.—The stock (A), being larger, will take two scions. The cut (B) is horizontal, and we split the stock right across at C. In order to do this we place the blade of the pruning-knife or the grafting-chisel perpendicularly on the top of the stock, and press upon it with both hands. If the wood is tough, we must make use of a mallet. The scions are placed one by one in the mouth, or in a vessel containing damp moss. When the cleft is two-thirds completed, we withdraw the implement to one side, so as to keep the incision always half-open. We place one scion at the other side, and using the implement or the handle of the mallet as a lever, open the incision so as to let in the scion completely. The insertion of the other scion is not more difficult; perhaps it will

Cleft-grafting with two scions.

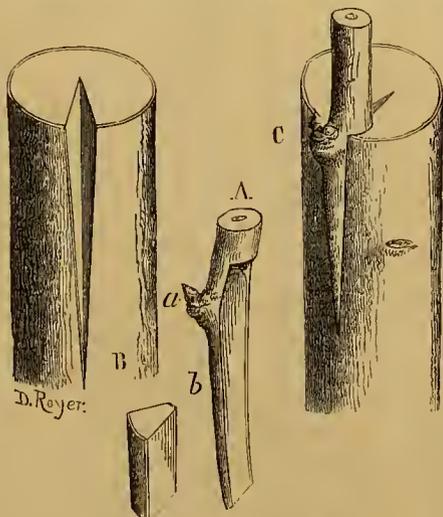

be necessary to introduce the blade of the implement into the cleft (c) at the centre of the cut and open it a little to facilitate the admission of the second scion. If the pressure of the implement should be disagreeable, a little wedge of box-wood might be temporarily introduced into the middle of the cleft (c). This would permit us to insert both scions easily without enlarging the cleft. Bandaging and mastic are necessary.

CLEFT-GRAFTING WITH AN INSERTED BUD.—When more than two scions are to be employed, two parallel clefts are to be made, so as to leave the pith in the centre untouched. A scion may then be inserted in each of the clefts. This might be termed double cleft-grafting, but the method of oblique cleft-grafting is to be preferred. This mode of grafting is based on

Cleft-grafting with an Inserted Bud.

the preparation of the scion. In cutting the scion (A) in the manner of the section (a'), we contrive to have on the back of the cut part (a) a bud (b), which will be inserted in the cleft (c) of the stock (B), as represented at c. From this will spring a vigorous scion, on which the wind will have no effect. It may be tied up against the upper part of the graft. Bandage and apply mastic. Our next illustration shows a scion (A),

Cleft-grafting with a Single Bud.

furnished with a single bud (a), which will be inserted in the cleft of the stock. At b is seen a section of the cut part of the scion; at B the cleft in the stock; and at c the scion finally inserted. Nothing further remains to be done except to apply the mastic, taking care not to rub off or injure the bud (a).

According to the manner in which the end of the scion is cut, the bud (a) may be placed level with the top of the stock, as shown at c, or lower down as at c in the preceding illustration. The incision (B) in the stock shows that this process is equally applicable to grafting by inlaying. By this method valuable scions may be multiplied, since as many grafts may be formed as there are buds.—C. Baltet.

(To be continued.)

THE KITCHEN GARDEN.

PRIZE ESSAY ON THE POTATO.

BY GEORGE MAW, F.S.A., G.S., L.S.

(Concluded from p. 26.)

7. ACCIDENTAL VARIATIONS OF RESULTS.

It has been necessary, in drawing our conclusions, to altogether avoid relying on the results of isolated experiments. Whatever precautions may be taken to insure uniformity in the conditions under which agricultural experiments are conducted, unaccountable anomalies in the result will be found to occur; variations which affect all agricultural crops, and which should be fully recognised and guarded against when inferences are drawn from experiments.

The only way to remove such sources of error is to throw together the average results of a number of independent experiments, so that the irregularities tending in either direction may neutralise each other. I would cite, by way of illustration, the individual trials making up the average results given under the first head. I have already stated that the average balance on 13 experiments, in favour of 2 oz. over 1 oz. sets, was 1 ton 13 cwt. 2 qrs. 7½ lbs. per acre; but if we come to details, it appears that, out of these 13 experiments, 5 show a result in favour of the 1 oz. sets, and 8 in favour of the 2 oz. This proportion, 8 to 5, taken by itself, is not very striking, and might be accidental; but when the sum of the weights of the gains in favour of the larger sets is placed against that in favour of the smaller sets, the proportion is increased to 25 to 5.

	Net Balances.			
	tons.	cwts.	qrs.	lbs.
The gains per acre on 8 experiments, in favour of 2 oz. sets over 1 oz. sets, is	27	8	3	22½
Whilst the gain on 5 experiments, in favour of 1 oz. sets, is but	5	12	2	6½

Leaving a balance in favour of 2 oz. over 1 oz. of 1 ton 13 cwt. 2 qrs. 7½ lbs. per acre.

Even this result taken singly might be merely accidental; but when the other steps in the same series show precisely similar tendencies, the general tenor must be accepted as confirming the indications given by the majority of the individual experiments.

In comparing the produce of 2 oz. and 4 oz. sets, out of 12 experiments, the net results of 8 are in favour of the 4 oz. sets, and 4 in favour of the 2 oz.

	Net Balances.			
	tons.	cwts.	qrs.	lbs.
The gains per acre on the 8 experiments, in favour of the 4 oz. sets, amount to	28	19	3	2½
And those on the 4 experiments, in favour of the 2 oz. sets	9	15	2	11½

Leaving a balance in favour of the 4 oz. over the 2 oz. sets of 1 ton 12 cwt. 0 qrs. 1½ lbs. per acre.

In comparing the produce of 4 oz. and 6 oz. sets, out of 9 experiments, 7 are in favour of the larger sets, and 2 of the smaller.

	Net Balances.			
	tons.	cwts.	qrs.	lbs.
The gains per acre on the 7 experiments, in favour of the 6 oz. sets, amounted to	30	0	2	15½
These on the 2 experiments, in favour of the 4 oz. sets, to	12	12	2	10½

Leaving a balance in favour of the 6 oz. over the 4 oz. sets of 1 ton 18 cwt. 2 qr. 19 lbs. per acre net.

Advancing from 6 to 8 oz. sets, out of 5 experiments 2 are in favour of 8 oz., and 3 in favour of 6 oz. sets.

	Net Balances.			
	tons.	cwts.	qrs.	lbs.
The sum of the gains per acre on 2 experiments, in favour of 8 oz. sets, amounted to	7	13	3	22
And those on 3 experiments, in favour of 6 oz. sets, amounted to	6	17	2	27

Leaving a net balance in favour of 8 oz. over 6 oz. sets, of 5 experiments, averaging 3 cwt. 0 qrs. 27 lbs. per acre.

Of the whole series of 39 experiments, 25 were in favour of large sets, and 14 showed an opposite tendency; but the proportion borne between these numbers does not fully represent

the actual result, which is more fairly stated by the weights of the balances on either side; for whilst the gains on the 25 (acres) experiments calculated per acre amounted to 9½ tons 3 cwt. 1 qr. 6½ lbs. in favour of large sets, the gain (14 acres) on the 14 experiments favourable to the smaller sets amounted to only 3½ tons 17 cwt. 1 qr. 27½ lbs., leaving (after setting the gains against the losses) an average net balance, on the 39 comparisons, of more than 1 to 10 cwt. in favour of the larger sets on each advance, namely, from 1 to 2 ozs., from 2 to 4 ozs., from 4 to 6 ozs., and from 6 to 8 ozs. I have been particular in noticing these exceptional irregularities, and their general bearing on the tenor of the experiments, as an element inseparable from agricultural experiments, and as requiring the fullest recognition in the estimation of results.

It now remains briefly to recapitulate the general bearing of the experiments, the results of which have been described in detail.

Firstly. Every increase in the size of the set, from 1 oz. up to 8 ozs. in weight, produces an increase in the crop much greater than the additional weight of the set planted. *The net profit* over and above the extra weight of the sets in planting 4 oz. sets in lieu of 1 oz. sets, amounted on the whole series of experiments to between 3 and 4 tons per acre; and the further *profit* on the increase of the size of the set from 4 ozs. to 8 ozs., averaged about 5 tons an acre; all the intermediate steps partaking proportionately of the increase.

Secondly. The advantages in favour of the large sets is more marked in the late than in the early varieties.

Thirdly. In the use of small sets of from 1 oz. to 3 ozs. in weight, a larger balance over and above the weight of the sets was obtained by planting from 6 to 9 inches apart in the rows than at wider intervals.

Fourthly. Increasing the intervals at which the sets are planted, even of the largest size, in the rows to more than 12 inches, diminishes the crop, and the wider intervals induce no increase in the weight of the produce of the individual sets.

Fifthly. It may be broadly stated that the weight of the crop is proportionate to the weight per acre of the sets, and that small sets will produce the same crop as an *equal weight per acre* of large sets. The fact is, however, of limited application, as a weight of very small sets equal to a weight of full-sized potatoes could not be got into the ground, except by planting them so close as to be prejudicial to the crop. The advantage, therefore, of large sets remains practically unimpaired.

Sixthly. *Weight for weight* cut sets produce, as nearly as possible, the same weight per acre as whole potatoes; but for the reasons given above, the weight of the sets should not be reduced by subdivision.

Seventhly. Smaller sets give a larger produce in proportion to their weight than the larger sets.

Eighthly. When the intervals between the sets in the rows are diminished to less than a foot, the produce of *each individual set* is proportionately diminished. Though this is not necessarily accompanied by a diminution of the weight of the crop, no increase in the produce of each individual set is caused by placing the sets at intervals wider than a foot.

Ninthly. With reference to the relative produce of different varieties, a *Late Red* sort takes the precedence throughout the experiments; and of the several varieties of Fluke, "Spencer's King of Flukes" and "The Queen of Flukes" are much more prolific than the ordinary variety.

How to Kill Weeds.—By attending to the following directions, weeds may be completely extirpated:—1. Study their habits. Without this you are working in the dark. You are shooting without taking aim, and are more likely to miss than to hit. 2. Have faith that weeds can be killed. 3. Should you, for the first year or two, see little benefit from your labour, do not relax your efforts. You will certainly triumph in the end. This is the experience of all gardeners; and a firm conviction of this truth is one of the strongest incentives to perseverance. 4. Be forehanded with your work. This is exceedingly important. It is so not merely because weed-plants can be killed easily just as they commence to grow, but it often happens that many weeds actually go to seed before they get large enough to attract attention. Many think it impossible to free the land of Couch or Quick Grass (*Triticum repens*). But it will be found that they are *not* forehanded with their work. They apply labour enough, but it is too late. They let the plants grow until the ground is covered with the leaves of the Couch, and *then* they hoe and rake and cultivate, and maybe fork out as many roots as possible. But they cannot get out the whole. The roots are broken into small pieces, and each piece produces a new plant, which soon pushes out its roots in all directions in the loose and mellow soil. Had the work been commenced *before* the Couch plants

pushed out their leaves, and been kept up so vigorously and continuously that the young shoots could not get above the surface, and the soil constantly cultivated during the hot dry summer months, every Couch plant would be destroyed. We have tried the plan, and know that Couch can be effectually got rid of in this way. But no half-way measures will succeed with it. 5. Burn all the thistle-heads and other weeds that are cleaned out of the garden. 6. Look to the manure. This is a fruitful source of weeds.

THE ARBORETUM.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE MEDLAR THORN (CRATEGUS ARONIA).

This is a hardy, robust, rapid-growing thorn, and one of the finest of the fine genus to which it belongs. It forms a tree from fifteen to twenty-five feet high, with a straight stem and upright rigid spindling branches, thickly furnished with short spray. It is a native of mountainous parts of Greece and

Leaves, 2½ inches broad and 2¼ inches in length, including the footstalk.

the Levant. It grows well in any good garden soil, and is easily increased by means of grafting on the common thorn. It was first introduced in 1810. It forms a fine object, both when in flower or in fruit, and is admirably adapted for planting in small gardens or places of limited extent. It is never attacked by the larva of the thorn moth, which so infests and destroys the foliage of the common hawthorn and some other kinds.

The leaves are rather large, deeply divided into five open bluntish lobes, wedge-shaped or tapering to the base, and when fully grown smooth and glossy green above, and downy beneath. The lobes are in equal pairs, with the terminal one frequently trifid, and, except three or four unequal coarse teeth at the apex, all of them are quite entire on the edges. The stipules at the base of the leaves are rather large, one-sided, cockscomb-shaped, and irregularly and deeply cut on the outer edge. The flowers are rather large, pure white, very fragrant, and produced in great profusion in compact corymbs in June, long after the common hawthorn and most of the other kinds have done flowering.

The fruit is globular, very large, bright yellow, and mostly contains two bony seeds; when ripe, in the end of August, it has an agreeable taste, and hangs on the tree till the leaves drop off in November or even later. It is sometimes called *Crataegus fissa*.

PINE TREES AS MEDICINAL AGENTS.

ALTHOUGH some forests are regarded as sources of malaria, and oak trees and hazel hushes have been counted insalubrious in Europe, like the tamarind tree in the East, yet the air of pine forests appears always grateful to the lungs, and has been considered wholesome, although of its absolute curative influence there is little evidence, and, indeed, it must be difficult to procure such. The idea of pine forests exercising a balmy influence on the lungs is a very ancient one. Pliny considered that the air of pine forests was more useful in phthisis and in convalescence from acute diseases than the voyage to Egypt recommended in such cases in those days. Both Bournemouth and Arcachon at the present day owe a good deal of their reputation to their pine woods. The air of the latter is said to be distinctly sedative. On the whole, then, the air of the pine woods of the Black Forest may be regarded as an element entering into the consideration of the value of its baths. But besides merely inhaling the air of its forests, people have of late years made much use of the products of pine in baths, vapour baths, and inhalations. Even this is not entirely modern; for the ancients recommended chiefly the internal use of decoctions of strobili and of pine tops, and thought pine nuts very useful in diseases of the chest; and at a more modern time, besides the internal use of drinks made from the spruce and the tar-water so long in vogue, we had inhalations of tar and of various resins. The ancients did, indeed, recommend in gout baths of water in which cedar wood had been boiled, but the use of the pine-extract bath is quite modern. It has spread rapidly, and is in use at Gleisweiler, Rehburg, Liebenstein, Ruhla, and Eisenach. These aromatic extracts are procured from various pines—as from the *Abies excelsa* or Norway spruce, silver fir, *Pinus sylvestris* or Scotch fir, *Pinus maritima* or Bordeaux pine, the Weymouth pine, also from the common larch, and the most fragrant of all, from *P. pumilio*, the mountain pine. The baths vary considerably in strength and in odour, according to the way in which they are prepared. The commonest way of making the bath is by adding to common water a certain quantity of the decoction got by passing steam through the young pine-tops.—*Lancet*.

A Tree Hotel.—Of all the hotels in the world, the very oddest is a lonely one in California, on the road between San José and Santa Cruz. Imagine ten immense trees standing a few feet apart and hollow inside; these are the hotel, neat, breezy, and romantic. The largest tree is sixty-five feet round, and contains a sitting-room. All about this tree is a garden of flowers and evergreens. The drawing-room is a bower made of redwood, evergreens, and madrona branches. For bed-chambers there are nine great hollow trees, whitewashed or papered, and having doors cut to fit the shape of the holes. Literature finds a place in a leaning stump, dubbed "the library."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Prunus tomentosa.—This is one of the handsomest of spring-flowering hardy Japanese shrubs. It is also one of the earliest to bloom, commencing to do so in the beginning of March, and producing a succession of flowers up to some time in April. The flowers are large and white, with a very slight tinge of flesh-colour at the base, and are so numerous that they completely cover the shrub, which is little more than three feet high, and forms a very branching, compact, and roundish bush. It is propagated by cuttings and seed, which it yields freely, and will, no doubt, prove a valuable acquisition to those who supply our flower markets.

Cerasus Lannesiana.—This species, which was sent from Japan to the Jardin d'Acclimatation, in the Bois de Boulogne, in 1870, by M. Lannes, of Montebello, forms a valuable addition to our hardy ornamental flowering shrubs. In its general aspect it resembles the common wild cherry of our woods, and flowers in the beginning of April, when the tree is almost entirely hidden beneath a dense mass of rose-coloured flowers, producing a very striking effect. As the plants flower when very small, they may be grown in pots for the market. The tree is very hardy, and will grow in any soil that suits the wild cherry.

The Wax of Plants.—Professor de Bary publishes a paper on this subject in the *Botanische Zeitung*, thence abstracted into *Nature*. The wax does not appear to be a simple coating on the surface, and to form a continuous layer, as though laid on with a brush. It is found to be a dense forest of minute hairs of wax, each having one end on the epidermis, the other either rising straight up or rolled or curled amongst its neighbours. This matting of the waxen hairs is often sufficiently dense to give the surface, when viewed by the microscope, the appearance of a continuous layer, though a good section of the leaf or skin of the fruit indicates its structure. The question as to what part of the epidermis or subepidermal tissue forms the source of the wax is most beautifully and clearly answered. Professor de Bary states that it is impossible to discover the slightest trace of wax in the cell contents, or to entertain the theory that chlorophyll is partly made of wax. The locality in which the wax can first be detected is the cuticle and the cuticularised elements of the epidermis cells.

GARDENING FOR AUGUST.

THE INDOOR GARDEN.

BY T. BAINES, SOUTHGATE.

Conservatory.—The deficiency of blooming plants in conservatories at present may be compensated by a liberal admixture of such things as *Dracaenas* and *Coleus*. Of the former take such kinds as *Cooperii*, *ferrea*, and *terminalis*; the bright markings of their leaves will supply the place of flowers, and the plants will not receive injury for the next two months by being placed in a house without fire heat; neither will they suffer so much as flowering plants would by standing somewhat closely, the greater amount of air and lower temperature of the house, compared with the stove where they have grown, having the effect of stopping them from making much growth whilst in the conservatory. The different varieties of *Coleus* should be placed so as to get as much light as possible, otherwise they become drawn and have an unsightly appearance. The old *Plumbago capensis* is another useful plant for this time of the year, which is not grown nearly so much as it deserves to be. The present is a good time to propagate it. The small half-ripe side shoots will strike freely inserted in small pots under bell-glasses in a little heat. These, when struck, should be encouraged to make growth before the autumn gets too far advanced. They should be wintered in a temperature of 45° or 50°. In the spring they should be headed down and potted in six-inch or eight-inch pots, using good fibrous loam. If desired, some may be grown on in larger pots, but for general decoration they are more useful in a comparatively small state. The plants will last for years by cutting them back in the spring just before they commence growth and when they have broken, removing a portion of the old soil, which replace by new material, returning them to the same or a size larger pot. *Fuchsias* should have their seed pods picked off regularly, or they soon cease to flower freely; they ought to be supplied twice a week with weak manure water. *Double Petunias* are very useful at this season, either as decorative plants or for furnishing cut flowers. These should receive regular attention in the way of stopping and tying, to induce them to break back, or, from their quick somewhat straggling habit of growth, they become unsightly. *Lilium auratum* is a most useful subject for conservatory decoration at this season, but should not be introduced in too great numbers at a time, as its perfume, being so powerful, is oppressive. Attend well to the different varieties of *Lilium lancifolium*, by keeping them neatly tied out, and supplying them regularly two or three times a week with manure water, otherwise the soil becomes exhausted, and they lose their bottom leaves, which destroys half the beauty of the plants. They must on no account be allowed, at this season especially, to suffer from want of water, even for ever so short a time, or the same mishap will follow. *Chrysanthemums* should at once receive their final shift, using from eight to ten, or twelve inch pots, according to the size the plants are required to grow; ten-inch I find the most useful size. No plants are more useful, or more easily grown than *Chrysanthemums*, and that are oftener seen below mediocrity than otherwise, and this generally through an insufficiency of water in any stage of their growth. After the roots have got fairly hold of the soil in their blooming pots, they should receive strong manure water every other time they are watered. They will bear it as strong as any plant in cultivation. The mushroom-shaped style of training is the most in favour with those who grow them for exhibition, but it is unnatural and useless for general decorative purposes. Plants of the larger varieties, confined to from two to five shoots each, neatly tied to a stick, the head of the plant brought out to about twice or thrice the diameter of the pots they occupy, will be found the most useful, and this will give them ample room for the development of their foliage, which, if they are well grown, will be of the darkest green. As the shoots of the large kinds branch out in growth, they should be thinned to the number of flowers the plants are intended to carry, leaving one flower to each shoot. The plants will carry from six to eighteen, according to their strength. To those who have not tried this thinning process, it may appear a great sacrifice in quantity; but either for cutting or for decoration on the plant, one good flower is worth three inferior ones. And flowers so treated will last fresh on the plant fully a third longer than others that have been insufficiently thinned. The *Pompones* also require thinning, but not so much as the large varieties, neither in the reduction of the number of shoots nor to the number of flowers each shoot will carry; these may be left from three to half a dozen to each terminal shoot. The first batch of *Cinerarias* should now be in their flowering pots, six-inch ones, and should be encouraged by watering once or twice a week with manure water; shade slightly in the sunny part of the day, and keep them quite clean from aphides. *Primulas* should be similarly treated, with the

exception of keeping them a little drier at the root. Strike more cuttings of Hydrangeas, for succession. Attend well to Euphorbias, Poinsettias, Salvias, Bouvardias, and things in general for winter blooming. Press of other work frequently causes these things to be somewhat neglected, but in the case of quick-growing plants of this description, neglect is fatal to their flowering satisfactorily when the time comes that they are required.

Stove.—Attend to the training of climbing plants, or they soon get a confused mass. Keep a diligent look-out for insects of all kinds, for they increase with the high temperature of the season, and if left even for a time entail much more labour and do a great amount of injury. Give now a little more air, less shade, and less water at the root, as well as in the atmosphere. This will assist the season's growth to ripen; but do not reduce the temperature of the stove, as we see frequently done, until the ripening process is complete, that is, the wood well matured and hard. Plants that are prematurely put to rest by the unnatural method of reducing the temperature before the growth is ripened, are almost certain to start into growth when not wanted, during the application of the extra heat required during severe winter weather; in which case it is useless to expect a satisfactory amount of bloom. Allamandas, grown in pots with the intention of training them on wire or wooden trellises, should have their branches allowed to grow loosely upright, until they are either opening their first flower buds, or nearly so; as, if trained down as they make their growth, they never bloom satisfactorily, as when the point of the shoot is brought down lower than the head of the plant, the first effort the plant makes is to adjust the balance of the sap, so rudely disturbed, by pushing the eyes of the shoots that are bent over the top of the trellis, and so starves the points of the shoots from which the bloom ought to proceed; and this holds good of all plants of a similar character.

Fern Houses.—Numbers of seedlings will make their appearance of some varieties, such as Adiantums, Lomarias, Davallias, Dicksonias, and these, if carefully taken up without materially injuring their roots, and potted in small pots, after which kept a little close until they get established, will be found very useful, either for standing amongst the larger plants, filling Fern-cases, or for decoration in other places apart from the Fern-house proper. All the stock should be gone over repeatedly during the season of growth with brush and sponge, in order to remove any insects that will now thrive apace with the warmth of the season, and which, if left to themselves even for a comparatively short time, entail a great amount of labour, and spoil the appearance of the plants.

Azaleas.—Continue to encourage the growth of these by closing the house early—say by four o'clock, syringing well overhead, and by throwing an abundance of water about the paths and floors of the house. It should be borne in mind that these are hill region plants, and that, in a state of nature, they grow in a moist atmosphere, different from what they often receive under cultivation, where we see them making their young growth with small sickly foliage. Azaleas are plants not easily killed, and consequently exist for years under such treatment, but they bear no comparison with plants well-grown.

Hard-wooded Greenhouse Plants.—Some of these plants will now have completed their growth, and may be placed in a sheltered place out of doors, where they will get a moderate amount of sunshine, which will harden their growth and help them to get through the dull autumn and winter months, without the attacks of that certain visitant to unripe foliage—mildew. The stock should be gone over twice a day in bright weather to see that nothing suffers from want of water.

Orchids.—Continue to encourage the completion of the growth ere short days are upon us, as plants that make and mature their growth whilst we have a maximum amount of light, are certain to flower more satisfactorily than growth that is made under opposite conditions. The whole stock should be gone over, so as to give it a thorough cleaning from scale, &c., and the pots may with advantage be thinly surfaced with a little chopped sphagnum and peat, which will protect the roots from attacks of insects. For scale, to one gallon of rain water, add eight ounces of soft soap, one ounce of tobacco, and three table-spoonfuls of spirits of turpentine; stir well, and let the mixture stand forty-eight hours; then strain it through a cloth and it is ready for use.

Heaths.—Encourage all, but especially the summer-flowering kinds to make their growth. In case of such as have almost completed it, move them out of doors, where they will receive all the light and air possible; but guard the pots from the full action of the sun, otherwise the roots may suffer, more especially such pots as are well filled with roots. They ought to stand on six inches of ashes to exclude worms, and if there are no means at hand to protect them from drenching rains, they should be laid down on one side during heavy rainfall.

THE FLOWER GARDEN FOR AUGUST.

BY GEORGE WESTLAND, WITLEY COURT.

FLOWER GARDENS are not in such good dress as they usually are at this season, owing to the long continuation of wet and the violent storms we have experienced, from which flower garden plants in some parts have suffered severely. But now that the weather is more favourable to their development we, in all probability, will be amply rewarded with an abundant autumn display, as the plants are strong and healthy. Great care should now be exercised in maintaining perfect order, neatness, and exactitude in preserving the outlines distinct in the training of the plants. The edging lines should be rendered faultless, as a bed with a broken edging is never satisfactory. Keep down weeds and have the grass neatly cut and in perfect order, for without the high polish of perfect keeping our gardens never give the looked-for enjoyment any more than would a disorderly drawing-room, however costly its adornments. Continue to propagate perennial and biennial plants. Transplant seedlings and such cuttings as were rooted early. Pay every attention to plants intended for spring embellishment in the reserve garden. After the middle of the month a sowing should be made of annuals intended for spring blooming, such as *Alyssum calycinum*, *Collinsia bicolor* and *verna*, *Lasthenia californica*, *Limnanthes Douglasii*, *Saponaria*, &c. Should the weather continue hot and dry, watering and other encouragements to growth should be attended to. Many of the foliage plants and *Violas*, *Verbenas*, *Calceolarias*, &c., are now benefited by liberal treatment and frequent applications of manure water. The propagation of bedding plants for next year should be commenced, but it will first be necessary to determine how the garden is to be planted so as to make sure of the quantities of plants of each kind determined upon, and thus prevent a useless multiplication of those not required. This regulates the space at command for wintering them in.

Geraniums may be propagated in shallow boxes, store pans, or in beds in the open border, and, when space can be afforded them, so as to have them potted up singly in autumn, the latter method is a sure and excellent one, as they make fine plants, and but little labour is necessary in preparing the beds for them; a layer of leaf soil and sand laid over the surface of the border and rendered solid, into which the cuttings should be dibbled firmly, and the soil settled about them with a good watering, finishes the operation, no further care than an occasional watering being requisite. The selection of cuttings is an important matter, and when these are selected in a firm state, rooting may almost be looked upon as a certainty. We prefer short firm cuttings, as they always produce the most compact plants. For the boxes, use loam, leaf soil, and sand, and place a layer of the rougher material over the drainage, previous to using the finer soil. The variegated varieties are more manageable in pots, and if space is available, we prefer to winter them singly in pots, as by this means they make the finest plants. According to the size of the pot, from one to twenty cuttings may be inserted in each. The pots should be well drained, using a compost of equal parts of loam, decayed dung, and leaf soil, with a free admixture of sand. After firmly inserting the cuttings, plunge the pots in frames that are fully exposed, and finish with a good watering. They will root with or without lights in favourable weather, but if lights are employed, a free circulation of air is indispensable.

Verbenas should now be propagated to insure their being well established and hardened off before winter. Much of the difficulty experienced in wintering *Verbenas* is traceable to the enfeebled state of the plants, caused by late propagation, which gives them no chance of recruiting their energy before the winter sets in. *Verbenas* should be propagated at once, and for this purpose we prefer pans well drained, over which is placed a layer of turfy loam and dung, filling up with over two inches of light soil and sand. Into this dibble the cuttings one and a half inches apart, and place the pans in frames that have been previously prepared, having as much fermenting material placed under them as will occasion a gentle heat. Plunge the pans in this bed, give a good watering, and thoroughly shade from sun, as they must never flag. By degrees as the plants become established remove the lights until they will stand full exposure. Then thin out the plants as they may require it. They will root equally well in a layer of soil placed over the surface without the pans, and lifted when rooted; but if the pans are thoroughly prepared with such material as will produce a free growth, we obtain no real advantage by so doing. *Heliotropes*, *Petunias*, &c., may also be propagated early in the month, so as to have them strong and healthy before winter. Layer and strike *Carnations* from cuttings. It is difficult to have too many of these; frequent sprinklings from a fine rose greatly facilitate their rooting. Plant out early rooted *Pinks* in prepared beds. Hedges should now be trimmed without delay. Shrubbery borders should be seen to and the growth regulated, so that the finer plants may not be damaged by being overgrown. More particularly will this timely attention be necessary when common *Laurel* and other free-

growing shrubs are planted to cover the ground. Such subjects must be kept in subordination, so as to allow perfect freedom of growth and every facility to ripen their wood. Such evergreens as are grown for the embellishment of French and geometrical gardens, should be carefully cut in, so as to preserve the desired form. Such plants as Yews, Cypress, Thujas, &c., may be cut into form by means of the shears; but the larger-leaved plants, such as Hollies, Bays, &c., must be kept trimmed by the knife, so as not to cut the leaves. Bays and Portugal Laurels we do not find benefited by much pruning at this season, for when well established they make very regular growth, and, with the exception of a few straggling shoots at this time of year pruning should be deferred until spring, as they look far more natural and stand the winter better.

THE FRUIT GARDEN FOR AUGUST.

BY WILLIAM TILLERY, WELBECK.

Outdoor Fruits.—During the past month the succession of terrific thunderstorms has been almost unparalleled in the midland districts. On the 9th, 11th, 12th, 13th, and 14th ult., above four inches of rain fell; and great floods were the consequence, damaging the fruit crops, especially Strawberries and Cherries. A fine dry period, with a tropical heat, set in on the 15th, which continued till the 24th, when other violent thunderstorms occurred on the 25th and 26th, with deluges of rain, making the total rainfall at the end of the month nearly six inches. All the dwarf pyramidal and bush trees of Apples and Pears, after such heavy rains, are making great quantities of watery shoots, and will want pinching in persistently. Fruit trees on walls are likewise making very gross shoots, and will want carefully disbudging, thinning, and stopping, so as to get the wood well ripened. Apricots, Peaches, and Nectarines on walls, are very thinly cropped this year in a general way, so that every attention should be paid to the trees to insure the prospect of a good crop of fruit next year. All the old canes of Raspberries done bearing should now be cut away, and the young shoots thinned and tied to stakes, so as to preserve them from high winds. New plantations of Strawberries if planted early this month will bear excellent crops next year. If some early layered runners are used for the purpose, the plants will be much stronger, and will not suffer when planted out. Where the earliest forced Strawberries have been planted out it will be found that they will yield a good supply in autumn, should the weather be favourable. Strawberry plants layered in July for forcing will now want shifting into their fruiting pots, using a good strong loam, with a little well rotted dung mixed with it. Press the soil rather firmly in the pots round the plants, and place a little soot above the drainage to prevent worms entering. I find pots of about five inches in diameter at the top are quite large enough to grow Strawberries to the largest size, and they take up less room on the shelves. When all are potted they should be placed in an open, warm situation, and watering should be well attended to, but should the autumn be as wet as the summer has been, this will be unnecessary.

Vineries.—Give the earliest house all the air possible as soon as the wood is well ripened, so as to bring the Vines into a state of rest. The earliest pot Vines will now have their canes well browned and ripened, and may be placed in the open air. If heavy rains occur in the autumn, the pots may be placed on their sides, so that the roots may not get drenched too much, before they are placed in the pits or houses for early forcing. In dull, damp weather, still give a little fire heat to the late Vineries, so as to get the Grapes thoroughly coloured by the end of September or middle of October.

Peach Houses.—The Peach and Nectarine trees in the late houses will now require every possible assistance to ripen the fruits perfectly, by exposing them to the direct influence of the sun and air. When the fruits are all gathered, the foliage must be kept clean and healthy by repeated syringings; sometimes brown scale puts in an appearance, but it must be eradicated as soon as detected. This pest soon diffuses over the young shoots and leaves a black sticky exuvia, but a strong solution of soft soap or Gishurst Compound, put on with the syringe or engine, will extirpate it, if taken in time. If the borders are dry after the crop is off, a good soaking of manure water will greatly assist the trees in ripening their buds.

Orchard House.—Syringings must be discontinued as soon as the fruit begins to ripen, and only as much water given to the roots as will prevent the trees from suffering. All the air possible must be given, and in very hot days damping the floors and stages will do something to save watering and keep the air healthier for the trees. Keep pinching all strong-growing shoots, on purpose to encourage strength in the weaker ones, and to keep the trees in form. Trees

in pots, that have ripened their fruit, may now be placed out of doors in a sunny situation, and if the pots are plunged in the ground it will save some watering at the roots in dry weather.

Figs.—The second crop will now be ripening, and if the foliage has been kept clean and healthy the fruit will now be in the highest perfection as regards size and flavour. I find it best to grow a select list of Figs, for many new varieties have lately been introduced, which are not so good as some of the older sorts for pot cultivation. De la Madeleine is a first-rate early Fig. Bourjassote Grise is another high-flavoured sort, and a sure bearer in pots. Lec's Royal Vineyard Fig is fruiting with me for the first time, and will, I think, prove an excellent variety. White Marseilles, White Ischia, and Brunswick are old varieties, and no better can be grown.

Melons.—The latest put out plants will now want a little manure-water to force them on, and if they are grown in pits the surface of the bed may be mulched, to prevent the sun from drying the soil too much. The laterals will want frequent thinning and regulating, and a healthy foliage encouraged, for upon this is the flavour dependent. I have grown some excellent Melons this year in boxes placed in the front of a pine pit; the soil used in the boxes was some turfy loam from the top of a limestone rock. Only from three to four fruits were left on a plant, and they were of a large size for the sort, and the flavour very good. The varieties were Victory of Bath, Queen Emma, Colston Basset, Golden Perfection, and a seedling from the Scarlet Gem, of the same high flavour, but which grows double the size of that fine early sort.

Cucumbers.—Late Cucumbers in frames will now want nearly daily attention in the way of stopping each shoot after the fruit is set, and placing them on a piece of slate or glass. Seed must now be sown to furnish plants for the winter supply in the house or pit. When some favourite sort is wanted for fruiting in the autumn, cuttings of it may now be struck to keep up the supply when the older plants have done bearing. Varieties of Cucumbers are now almost endless, and every gardener has his favourite kind for bearing in the winter, or for summer growth. It is the best way when a good free winter-setting variety is secured and proved, to take some trouble to save seed from a plant grown for the purpose, so as to keep the seed true to name.

THE PINERY FOR AUGUST.

BY JAMES BARNES.

As soon as the fruit has been well ripened and cut, the first opportunity should be taken to clear out and thoroughly cleanse the compartment by washing the glass, woodwork, and walls with water. Then prepare some boiling water, with which incorporate newly burned lime, sulphur vivum, and some fresh soot, and with this mixture give the walls, flues, and all corners a good washing twice, so as to fill up every crevice. The woodwork should also be painted over with good old white-lead mixed with boiled oil. After this all will become sweet, wholesome, and water-tight for some time to come. See to joints of the pipes, and examine and cleanse out both pipes and boiler. See also to the flues, fireplace, and bars, and have all properly adjusted, and in good working order. If the houses are heated only by flues, examine and clean them thoroughly, and wash them over twice, as above directed, in order to have all crevices stopped and in good working order. Renovate and renew all plunging materials, and lose no time in filling up again with fruiting plants that are about to start, for autumn and winter use. Encourage succession plants in every stage to make vigorous, sturdy growth by a kindly bottom heat and a strong atmospheric one, applications of good clear tepid manure water at root, and heavy applications of clear soot water from the engine or syringe, early in the afternoon, should be given, and air applied freely night and day. Suckers, of course, should be taken off as fast as the fruit is cut, with a piece of the old stem adhering to them, which assists holding them firmly in their pots, supporting them without a check till rooted, which they will do in a very short time on a kindly bottom heat, and grow on without loss of time. Unless suckers are constantly potted on as they become ready at all seasons of the year, there must be a lack of fine-seasoned well-prepared fruiting plants ready for every day in the year, to fill at once the places of those removed. Respecting the choice of suckers, I always made it a rule to discard those of plants that produced a number of suckers, and also those from plants that did not produce a first-class perfect fruit, and I never potted a crown but from a new kind, or an extraordinarily well grown fruit. It was a well known fact that few had a more perfect or beautiful stock of Queen and other fine varieties of Pines than I had at Bicton, and there I left as fine a pit of well swelled, handsome fruit as could be seen. There were also succession plants in every stage of growth, to keep up in future a supply for every day in the year.

THE KITCHEN GARDEN FOR AUGUST.

BY JAMES BARNES.

Look well to hoeing and surface stirring amongst and about all growing crops whenever a hoe or scarifier can be used amongst them, taking advantage of dry, suitable weather for performing this most essential practice in vegetable culture, which is not for the sake of destroying weeds, vermin and their larvæ alone, neither of which can get a chance of putting in an appearance if this is properly and duly performed, but more especially for the sake of maintaining a healthy, pulverized, sweet preparation for all and every succeeding crop. There is little use of heavy applications of manure and deep culture without a clean, open, sweet, pulverized surface at all seasons, that froely admits the atmospheric influences and the rain as it falls. Never rake the earth's surface, as that would form it into an even-bond floor after the first rain, thus stagnating the growth of advancing vegetation. Don't pick the stones, but allow them to remain so as to assist in keeping open the soil and retaining moisture; but, instead, apply stones and rubble to heavy adhesive soil. Never let it be said that you hoe the earth's surface about and amongst your crops for the sake of destroying weeds, for the weeds should never have a chance to appear. First reckon on the many times you can perfectly perform hoeing and scari-fying amongst your crops before a weed has a chance to put in an appearance to the once you can when a crop of weeds has got established, and the earth's surface got hard and bound through exhaustion, and calculate how much you have lost in weight and value of different crops by encouraging a crop of weeds. Keep the soil always cropped, which can be done by foresight in laying your plaus; you can likewise improve the land by deep culture, change of crops, and constant surface stirrings. Trench in, at all seasons, all the comestable rubbish and refuse vegetation. A liberal supply of manure and methodical application of salt and air-slaked lime in suitable weather are also very beneficial.

August is an interesting and busy month in preparing for autumn sowings and plantings. Trench every spare bit of ground, and continue to plant out Broccoli, Borecoles, and Coleworts; the latter in full crop, and succession ones thickly on well-prepared ground. They do not require above a foot apart each way, to produce nice little sweet crisp heads, beginning to draw early for thinning, for in five or six weeks they are fully ready. Cauliflowers and Cape Broccoli plant out freely and often for autumn and winter use. Of Carrots, make the last outdoor sowing of Early Horn and Early Dutch on a warm, well-prepared border, the first week in the month. The proper season has now arrived for sowing Cabbage in full crop for autumn planting, to stand the winter for early use next spring. On late, cold situations, sow in the first week of this month; but on deeply cultivated, well-prepared land, light or open warm soils, never sow a full crop of Cabbage till the 12th of August. Earlier sowings are liable to run to seed in early spring, instead of forming nice heads pretty early. Prepare sweet, pulverized, and healthy soil, to which apply a dredging of turfy peat or wood ashes. Prick out plants a few inches apart as fast as they obtain a few leaves and can be handled safely. In order to maintain strength and sturdiness, choose a few good early varieties that will stand thick on the ground and turn in nimbly; four of these will grow or turn into use, and a second crop will be planted, before one large Cabbage can be turned to account. The little varieties, too, are much crisper, sweeter, and more convenient for table use than big cabbages; take such as Atkin's Matchless, Nonpareil, Shilling's Queen, Early Dwarf Barnes, Little Pixie, Early York, or Enfield Market, which are all nice quick-coming kinds, and do not require much room. Sow also Red Dutch, Brussels Sprouts, Savoys, and Borecole, to stand the winter for early planting next spring. Continue planting out Celery on a good bed, prepared as previously recommended, but thicker together as the season advances. Remove suckers; earth up, and soak with good water, when necessary, all growing crops. Carefully avoid choking and smothering their heads. Of Chervil make two sowings for autumn, winter, and early spring use; also of American and curled cress. Sow Cucumbers on gentle heat, in order to get strong plants for winter crops. Have the cucumber-house or pit thoroughly cleaned, painted, lime-washed with hot lime slaked with boiling water, and with it incorporate some fresh chimney soot and black sulphur; apply it all over the walls, floors, and every corner in a pains-taking, methodical manner: give two coats of it, which will not only eradicate all insects, mildew, bad smells, &c., but will prevent their appearance for the next season. Both curled and Batavian Endive plant in succession. Tie up or cover to bleach on dry days such as are ready for daily use, and make the last sowing the first week in this month. The new Batavian is a capital variety to sow now, for planting on warm borders or sloping banks to stand the winter and to turn in early in the spring. Their nice white close heads, so much like a Cos Lettuce, are ready long before a lettuce can

be had, or to take up through the winter to place under cover to bleach. Leeks attend to, earthing up to bleach, and make the last planting. Sow Lettuce about the 12th of this month. The hardy Brown Egyptian and Bath Brown Cos stand the winter the best, and are the finest flavoured of all Lettuces. Sow a little in the first week to plant out, and afterwards take up for placing in a house or frame, for winter use. Sow also a variety or two of the Cabbage kinds, such as Hardy White Dutch, Hammersmith, Lee's Green, &c. Sow Onions also about the 12th, to stand the winter for spring transplanting. The following are good kinds, viz.:—Tripoli, White Spanish, and Portugal; two-bladed Deptford and Silver-skinned for drawing young for winter use. Parsley—thin, clean, transplant, and cut back a part of the overgrown leaves. Fill boxes with good rich earth, into which transplant strong plants for housing for winter use; sow some in a box for obtaining early plants for spring border planting. It is a good plan now to sow a small breadth of Parsnips, in order to stand the winter, and to produce early summer roots. Sow Radishes in variety once a fortnight, in order to have a daily succession of nice crisp roots, for Radishes are never better than they are in September and October. To Sea-kale apply moderate dredgings of salt in dark showery weather, and give every possible encouragement to a strong, luxuriant growth in this invaluable, wholesome, and useful winter and spring vegetable. Methodical dredgings of soot, besides encouraging a luxuriant growth and large crowns, also exterminate the slug and grub. Look well to the stopping and thinning of Tomato shoots; encourage the growth and fast swelling of the bunches of fruit by timely clipping and thinning out. The small green fruits thus cut off are valuable for pickling. Put in cuttings of Tomatoes this month to stand in their stock-pots till the beginning of the new year, when they should be shaken out, repotted, and placed in boxes in kindly heat, or turned out against the walls or ends of vineries, peach houses, or any convenient corner to produce early, ripe fruit in spring. Stunted, hardened, well-rooted autumn cuttings produce stubby, short-jointed, fruitful shoots, and are quickly converted into a fruit-bearing condition, whilst seedlings favour luxuriance and take much time to get into a fruit-bearing state. Continue to sow little, quick-growing Turnips on spare spots, such as Potatoes have been cleared from, leaving them a little thicker on the ground when hoed at this season of the year. Their growth can be wonderfully encouraged by timely thinning, constant attention to surface stirring, and an occasional dredging in showery weather with dry wood ashes and a little guano intermixed. Pretty, young, free, and sweet Turnips may thus be secured the whole of the winter, and a batch of early greens in spring.

Herbs of all kinds should be gathered carefully while in bloom, on a dry day, and carefully dried in the shade in an airy room. Sow the hardy, prickly variety of Spinach on well-prepared ground on or about the 10th or 12th of August to secure strong, healthy, productive plants throughout the winter; make another small sowing ten or twelve days later, to stand thicker through the winter to produce in early spring, previous to the spring season coming in. Harvest Shallots and Garlic; tie them into bunches, and hang them up in dry open lifts, or place them in some dry cold situation. Bend down the foliage of Onions carefully, laying them all one way, with a pole, in order to encourage the growth of the bulbs; harvest them when ripe; choosing a fine dry day, draw or pull, and tie them into convenient bunches as fast as pulled, and hang up at once in open sheds, on rafters or beams, or any other handy place to dry gradually. Do not allow them to lie about on the ground night and day after being pulled, which is sure to make them hot, stinging, and rank to the taste. No one can enjoy a rank, strong, hard-baked Onion any more than they can a sunburnt, green, or strong Potato. By the bye, I have been sorry to observe, in my rambles for some weeks past, that the Potato disease is making serious havoc in some localities, and is now becoming general everywhere, and quite noticeable to a casual observer.

"A NEW PROFESSION."

We have received the following from an old correspondent. The want that is indicated is perfectly intelligible, and the suggestion is not unreasonable:—At a time when parents are at their wits' ends to know how to provide for their sons, any suggestion towards the establishment of a new profession is worthy of consideration. Now, it may be a fanciful notion of mine, but it has recently possessed me very strongly that horticulture might be elevated to the rank of a profession. There are not many encouraging signs of the times, but among the few that present themselves to our notice is an increased love of gardening. This is especially observable in the vast suburbs of London, where every householder, great or small, devotes himself strenuously to the cultivation of his

two acres, or his acre, or even his quarter acre of garden. As he occupies his house all the year round, he has an interest in his little bit of ground which can never be felt by the owners of vast acres of garden land, the beauty of which they never see, as Loudon holds them when the flowers are at their best. I have heard ladies, not of the middle classes, say that they have never seen their roses in bloom. It is very different with people having small gardens, who not only know every bed, but have a personal acquaintance with almost every flower. It is upon such people that gardening has so good a moral influence. But they are subject to great disappointments and are often sorely perplexed. A large proportion of the people of whom I speak cannot afford to "keep a gardener," and would not have work for one if they could. They are driven to the precarious assistance of men who, with the smallest possible knowledge of horticulture, work at high wages by the day. Even those who have money enough and soil enough to "keep a gardener" are fortunate if they can get one, at the ordinary wages of a curate, with any knowledge of his business. There is a great want among middle-class people in the neighbourhood of London and other great cities or towns of an intelligent knowledge of horticulture. People would be willing enough to pay for this knowledge if they could only get it. Our roses or our grape-vines develop symptoms of disease, and we do not know how to arrest it. It is easy enough in the case of the "human subject." We send for the doctor. We send for a man who has made medicine or surgery (perhaps both) the study of his life, and he tells us what to do, and, if necessary, he does it. Now, why should we not know to whom to send in our horticultural dilemmas? Why should we not have our diplomated horticulturists, to whom we may send to rescue our trees or flowers from disease or death? Surely it is a pleasanter occupation to bind roses or to prune fruit trees than to cut off human legs or arms and to extirpate horrid cancers? A thorough knowledge of botany and horticulture is not more difficult to attain, and is not less ennobling when attained, than an equal knowledge of surgery and medicine. Why, then, should these pursuits not be erected into a "gentlemanly profession;" why then should we have rare exceptions in a Repton or a Paxton? Of course, the question may suggest itself, "Will it pay?" I am quite disposed to think that it would. I, for my part, and I have heard others say the same, would often be glad to pay my guinea for a visit from a skilled horticulturist. Such visits are sure to recompense the employer. Large sums are annually lost to us by the ignorance of the ordinary run of jobbing gardeners, who are often as obstinate as they are ignorant, and will have their own way to the detriment of their masters. Of course, if a man can afford to give a hundred and fifty or two hundred a year to a head gardener, he may obtain an amount of skilled labour which will render him independent of this occasional assistance. Such men may keep family physicians, private tutors, domestic chaplains, &c., and may be independent of outside doctors, preceptors, and even clergymen. But I am not writing for such men, but for the middle classes, and I am convinced that to them it would be a great boon.—*Pall Mall Gazette.*

OBITUARY.

COLONEL CHALLONER.

We have to record the death of Colonel Challoner, which took place at Portnal Park, Virginia Water, on the 26th ultimo. The gallant Colonel was in his eighty-fifth year. In his younger days he was a zealous supporter of the Royal Horticultural Society, was for years a member of its councils, and frequently presided over the attractive fortnightly floral meetings which the Society used to hold at 21, Regent Street, in years gone by.

MR. AUGUSTUS SMITH.

We regret to announce the death of Mr. Augustus Smith, of Scilly, the owner of one of the most interesting gardens in England. He was an enthusiastic lover of plants and a most liberal distributor of the innumerable fine species his gardens contained. Being in a very mild climate, numbers of plants from the Cape of Good Hope, Australia, and other warm countries thrive in his garden at Tresco as if at home.

COVENT GARDEN MARKET.—August 2nd.

Flowers.—Among Japan and other Lilies in the market this week may be seen the fine old-fashioned blue African Lily (*Agapanthus umbellatus*), well furnished with noble heads of bloom. Gladioli, of the Breuchleyensis section, are also abundant; they are grown in six-inch pots, and are well bloomed; cut flowers of the same, from the open ground, also continue to be furnished. Double-blossomed Pelargoniums are plentiful, each head being large enough to make a little bouquet in itself; other kinds are also plentiful, but for late blooming, preference

is given to double sorts. Prominent among plants in pots are *Petunias*, among which a white double sort seems to be the greatest favourite. Many sorts of greenhouse plants are likewise plentiful, among which the most striking are the scarlet forms of *Kalosanthes*. Flowering stove plants are for the most part confined to cut flowers, which are used in the formation of the finer descriptions of bouquets. A little white *Bouvardia* is now becoming very popular, and as a bouquet flower it has few rivals. Fine-foliaged plants consist chiefly of *Cyperus alternifolius*; several *Ferns*, such as different kinds of *Pteris*, *Adiantum*, *Asplenium*, and *Polypodium*; and *Coleuses*, among which the old *C. Verschaffeltii* still plays the most prominent part. There are also some nice little plants of *Caladiums* and *Begonias*.

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM JULY 25TH TO JULY 31ST, INCLUSIVE.)

BY OUR OWN REPORTERS.

Acena myriophylla	Cyperus longus	Liatris spicata	Parmica cristata
Adenophora intermedia	Delphinium pallidum	Lilium pulchellum	Rhexia virginica
Lamarckiana	Desmodium canadense	Linaria vulgaris	Rudbeckia clemmatis
Agapanthus umbellatus	Dipsacus Fullonum	Lobelia syphilitica	Salvia purpurea
Anemone japonica	Sylvestris	Lupinus luteus	Salvia patula
Antirrhinum angustifolium	Dracocephalum speciosum	Lysimachia fistulosa	taraxacifolia
Argemone platyceras	Drosera longifolia	Monarda	Sanvitalia procumbens
Artemisia annua	Erianthus Ravenæ	Myricoccephalus	Scabiosa agrestis
Aster concolor	Eupatorium purpureum	Stuartii	Scutellaria galericulata
cordifolius	Foeniculum virescens	Myrtus tenuifolius	Sedum cyaneum
sericeus	Geranium Lambertianum	Nierembergia grandiflora	Ewersii
squarrosus	Gypsophila elegans	Nigella Fontanesiana	Jacquinii
undulatus	ramosa	Oenothera Drummondii	populifolium
Brizopyrum siculum	Hedysarum Onobrychis	Oxalis lasiaudra	pycnanthum
Callia coccinea	Helenium autumnale	Panicum capillare	Selliera radicans
Calandrinia nitida	Calliopsis Drummondii	Pascalia virginica	Sempervivum ruthenicum
Callimeris incisa	Campanula barbata	Pentstemon Jaffrayanum	Silene tatarica
Calliopsis Drummondii	Barrelieris pyramidalis	Menziesii	Solidago latifolia
Calliopsis Drummondii	Thomsonii	Phytocuma betonicifolium	Stachys durinacula
Calliopsis Drummondii	Catalpa bignonioides	Hibiscus Trionum	sarcpatria
Calliopsis Drummondii	Centaurea alpina	Holcus halepensis	Smithii
Calliopsis Drummondii	suavcolcus	Hypericum Coris	triuervis
Calliopsis Drummondii	Cerithe major	Impatiens glanduligera	Stevia purpurea
Calliopsis Drummondii	retorta	Ipomopsis elegans	Thymus Teucrium
Calliopsis Drummondii	Cleonia lusitanica	Justicia pedunculosa	Trachelium ceruleum
Calliopsis Drummondii	Convulvulus cantabricus	Liatris graminifolia	Veronica Buxbaumii
Calliopsis Drummondii	Coreopsis alata	Primella hysopifolia	Corymbosa
Calliopsis Drummondii			pinata
Calliopsis Drummondii			syriaca
Calliopsis Drummondii			Wahlenbergia grandiflora
Calliopsis Drummondii			Xeranthemum radiatum

Plants in this list are almost without exception such as have come into bloom during the past week.

THE GARDEN.

“This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE.”—*Shakespeare.*

THE MANAGEMENT OF KEW AND OUR BOTANIC GARDENS.

THE articles on the Hooker and Ayrton affair have brought to the surface a subject of the highest importance to horticulture. It is the great question—shall our public gardens be managed by men thoroughly conversant with the art of gardening, or by those who frequently have no knowledge whatever of it? In short, shall they be under the control of the best and most cultivated gardeners or under botanists? We cut the following passage from last Saturday's issue of a gardening contemporary:—“The attempt to separate the botanical from the horticultural department in such an establishment as Kew is, of course, absolutely absurd, and could not be carried out without the greatest injury to the utility of the garden.” We have never before seen in horticultural literature so much that is wholly wrong expressed in such a short passage. The separation of the horticultural from what is called the botanical department of such an establishment is not only not “absolutely absurd,” but it would prove the very greatest good that could befall it.

Horticulture is a profession embodying so many ramifications that it is difficult to find a man who possesses a good general knowledge of the whole. Men spend their lives at, and make their reputations from, such branches as fruit culture, as orchid culture, as arboriculture, and yet these are but a few of the divisions into which gardening has now grown. Difficult, however, as it is to secure a man with a good general knowledge of horticulture, we happily have in most civilised countries examples of brilliant success in this way. There are, for example, such men as the present curator of the botanic garden at Edinburgh, John Bain, late of the College Botanic Gardens at Dublin, Mr. Dominy of Chelsea, Mr. James Backhouse of York, M. Rivière of the Luxembourg Gardens at Paris, young Mr. Niven of Hull, and not a few others that we could name, who, gardeners in heart and soul, might be put forward as having something as near a perfect knowledge of the art of gardening, in its noblest aspects, as it is possible to attain. Yet, by our present system, we place such men under the direct control of a person who is, as a rule, utterly ignorant of the art, or science, or knowledge, or whatever it may be called, of horticulture. We could give, if space permitted, many instances to prove that “distinguished botanists” are as devoid of the knowledge necessary to keep a large collection of plants in good health as a housemaid. Nor do they, as a rule, pretend to any knowledge of the kind, and by giving into their hands the charge of a large garden and the control of an able gardener (it may be a man of genius), we injure ourselves and our art to a degree of which few have any conception. What should we think of builders or architects if they placed their most important works and their best men under the control of somebody who had never taken the least interest in building or architecture, but who had spent his life in assiduously examining and gathering stones? And such a plan is precisely analogous to what is followed in a good many public gardens.

And what is the result of this course? Just what we might expect—that all gardens not actually or virtually managed by real gardeners are generally in a poor, sometimes in a wretched, condition. Look at the Garden of Plants at Paris, which we see dragged into this discussion as an example of right management! Why, it is a standing disgrace to the very name of gardening, and about as ugly a plot of ground as one could see, except some of the Parisian cemeteries. And, travel where you will, you invariably find the botanic garden managed by the professed botanist hideous from the point of view of art or nature and, as regards collections, frequently inferior to private gardens or commercial ones. But in many cases extreme poverty frequently forms a good excuse.

How is it in the case of Kew? Never in the history of the world has a nation been so liberal to a public garden as England has been to it. £20,000 per year, and sometimes a good deal more, and as much as £60,000 for a single hot-house! When one considers the slender aid given by other nations to their public gardens, this reads like a fable. Yet in all the recent articles on the Kew affair, generous John Bull is incidentally alluded to as the meanest and most penurious of wretches. Well, for this princely sum what have we at Kew? Nothing to what such an immense revenue should entitle us. Take, for example, the collections of important types of vegetation. Ask any orchid-grower as to the state of the orchids at Kew and the extent of the collection, and he will most probably laugh with derision. There are scores of collections of orchids better grown and richer than those at Kew, as everybody knows who has the slightest acquaintance with orchid culture. Then go out of doors and look at the flower gardening. In this way it is an age behind some of the London parks, and we see the strange spectacle of such places as Battersea Park introducing abundance of beautiful change into its flower gardening in the shape of graceful and stately plants, while Kew lags behind. It is true the noble houses built in such a palatial manner by the Parliament or people of England, are well filled with large subjects, but can anything be more discreditable to the gardening of England than the general state of the plants in pots at Kew? Then look, again, to the question of novelties. Nobody thinks of looking to Kew for them. If we seek new conifers, or new and rare ferns, or new alpine plants of any class, we all have one or more gardens associated in our minds with such novelties, but we do not think of Kew in connection with them. It would be most unfair to expect that such a place as Kew should excel in everything; but, surely, from £20,000 per annum one would expect supreme excellence in some branches. And if the best collections of plants, and the best grown, are not at Kew, or not elsewhere, under the control of the botanist proper, where are they? In charge of our gardeners amateur and professional. Where is what is called our “scientific” horticulture? to adopt the phrase of the day, or, in plain English, where is our best and most advanced gardening? In the same good hands. And who are the pioneers—who are they who discover for us paths and pleasures new, in our always delightful gardens? Our gardeners only, and in that term are included all gentle and simple, rich or poor, who love their gardens. To name one single instance only, Mr. James Backhouse, of York, has done more to refine and ennoble gardening than all the botanists who ever had charge of a botanic garden. And this is no reflection on the botanist, whose real work lies in another field.

The best managers of botanic gardens are invariably such as have had a thorough gardener's training, like Dr. Moore of Dublin, or Mr. Niven of Hull—men who have lived all their days among large collections of living plants in gardens; and it by no means follows that such men, because first of all excellent gardeners, may not also be good botanists. It is almost impossible that they can be otherwise. Such gardeners and nurserymen as Mr. John Smith, late curator at Kew, and Mr. Atkius, now of Painswick, are accomplished botanists; but the botany comes to such men through a life among living plants in the garden, and is an accessory to a fuller knowledge of gardening. Such gardeners may be compared to architects and builders who build nobly, but whose practice, tastes, and intelligence lead them to understand the classification of the stones they use.

It may be objected that when a botanic garden is wholly under the charge of a professed gardener, the general collections might suffer from his partiality for a few common types. The answer is ready: by far the most complete and rare collections and the best grown are those in the possession of amateurs, gardeners, and nurserymen. The real danger lies in the opposite direction—that is when a mere botanist has sole control, as at Kew. He is apt to select a cultivator only, instead of a really accomplished botanic gardener. Now we want good cultivators in all our botanic gardens; but in a first-rate curator that skill should be quite subordinate to a wide knowledge of every type of vegetation grown in gardens. Hence,

to select a man merely because he happens to grow well some one or two classes of plants, is a dangerous blunder. For such an individual would probably be as awkward as a rhinoceros in a glass-house as regards other classes of greater importance. It should never be forgotten that the trees and plants which are of the highest importance in a botanic garden in this country, are such as are quite hardy in the open air, and that one may quickly acquire a reputation as a cultivator of pot plants, without knowing or caring for any hardy subjects. Hence the absolute necessity of selecting a curator possessing a general knowledge of, and love for, every family of the garden flora. We could give more than one instance in which serious damage has been done to a valuable collection, by placing it in the hands of a person with a merely one-sided knowledge of plants. It should also be borne in mind that when a botanist has the appointment of the curator of a garden, he is, as a rule, not apt to select a first-rate man. Many professional gardeners know living cultivated plants, that is to say, know the botany or the flora of a botanic garden far better than many botanists. Obviously, except in the case of a noble nature, our botanist director is not likely to select a man who knows more than he does himself about the plants in the garden—the only things that either the visitors or supporters of such care a straw about.

Therefore, while we may subscribe to the memorial to the Government, now being actively canvassed for, that those who are "responsible for the culture of the plants, should also have care of the heating apparatus," it should be clearly understood by all that the only person fitted to be "responsible for the culture of the plants" is a thoroughly intelligent professional gardener. The connection between botany and hot-house boilers must, even to botanists themselves, be ridiculous. The botanist should have no more to do with the cultivation or arrangement of the living plants, than the gardener, or curator, or whatever he may be called, has with the herbarium. Where, as in some botanic gardens, there is no collection of dried plants, there is no necessity for a botanist *pur sang*. The whole march of modern progress tends to affirm more and more the great good resulting from special attention or life-long devotion being given to any one profession or subject of inquiry. The inflexible law of evolution is sure to break up some day this unnatural subjection of the gardener to the botanist; and the sooner the better. The botanist has his collections, and the wide earth in which to gather them. He has no chance of competing with the gardener, until he has first had a gardener's training. And to learn gardening thoroughly, in the sense in which it should be known to one fitted to direct a botanic garden, it is necessary that the best part of a life be given to it. W. R.

AFTER THE SHOW.

"AFTER the Battle" is one of not the least important of recent great pictures, and after the show affords one time for reflection. As you are aware, I am not a chicken. I can go back nearly forty years, when the Chiswick shows were comparatively in a state of incubation; and now from my window I perceive the Birmingham mud is being cleaned from the winter boots indispensable on that occasion. But we will not speak of the weather, further than to remark that the singular privilege of the Royal mother was not vouchsafed to the younger son on the occasion. The state of the handsome but wretchedly managed park at Aston shows that the Birmingham town authorities have yet much to learn in the way of appropriate keeping of public institutions, and though they may plead as a justification that the "people" are unprepared for it and would not appreciate it, depend upon it that so long as public institutions are neglected and allowed to go to decay by the custodians of them, so long will the "wage paid" classes cease to respect them.

Well, before we go further, will anyone inform me why grounds like those at Aston should not have been, for the time being, if not for all time, made into a beautiful garden? To me it appeared there was no reason, except that Bacchus usurped in a great measure much of what Flora ought to have had. Perhaps some day we may get back to the good old times, when, at Chiswick, Gunter was content to vend his wares in a back shed, and when to be seen with anything hotter than an ice or a glass of cherry brandy was a crime. Well, of the show. The large tent, though much larger than that

at Nottingham, was neither in design, effect, nor furniture nearly so good. It was too flat, too formal, too lineal; it was made up of little pettinesses, without the visitor in any one place obtaining a striking view that made a lasting impression upon the eye. Granted that the nature of the ground—water a few inches from the surface—forbade what might be called a bold contour arrangement; is that any reason why a rustic bridge, or a rockery, with the water gurgling to its base, should not have been extemporised, fore and aft, so that a full view might have been obtained of the fairy scene? There was no reason but that of expense, and that would not have been great; while a mass of good rockwork would have been a lesson well worth studying in the vicinity.

The large tent was really enjoyable, but those "laues of canvas," long, damp, dark, and ague-giving, must be done away with. We have had a foretaste of the large tent, and nothing less than an extension of that system must be tolerated. Narrow tents may do for a country show, but when they gather people by tens of thousands at a time, breathing and ambulatory space must be found for them. Above all things, provide an elevated point of sight, so that those who cannot go through may pass over and be able to say, "I have seen the show." With crowds, some arrangement of this kind is indispensable.

But the great difficulty is to leave the beaten track; custom has a strong hold upon the Executive of the Royal Horticultural Society. "Whatever is," with them, "is right," and innovators are set down as troublesome people. However, we have at last got them fairly on the road, and what is better, it pays; and now we must insist upon their moving with the spirit of the times, and giving us our full measure of instruction and entertainment. Roundhay Park, Leeds, will next year form a grand tilting ground, and from what I have seen of the spirit of the Leeds folk at flower-show time, from the mayor downwards, I know the Society will receive a right hearty Yorkshire welcome. YE KEN WRA.

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM AUGUST 1ST TO AUGUST 7TH, INCLUSIVE.)

BY OUR OWN REPORTERS.

Achillea pectinata	Campanula Hohenackeri	Gaillardia Drummondii	Rudbeckia grandiflora

recurvatus	seseloides	Rubus discolor pl.	Verbera pulcherrima
sagittifolius	Francoa ramosa	Rudbeckia fulgida	Watsonia marginata
undulatus	sonchifolia		Zauschneria californica
Atriplex hortensis rubra			Zea Mays
Bidens ferulifolia			
Callistephus chinensis			
Campanula formosa			

Plants in this list are almost without exception such as have come into bloom during the past week.

The storm on Wednesday last did much damage to crops about London, especially in the south-east districts, in which rain fell in torrents. Two girls working in a market garden at Charlton were struck by the lightning, and one of them was so much injured, that it is doubtful if she will recover. Trees in different parts of the country were struck by the lightning and split into fragments.

NOTES OF THE WEEK.

— MR. GEORGE MAW has just introduced the true *Saxifraga mutata* from the Eugadine.

— THE Parisians are just now occupied in replanting large trees round the lakes in the Bois de Boulogne. These have been brought from the Forest of Sénard.

— THE beautiful *Asclepias tuberosa* is this season producing freely its showy bright orange-coloured flowers in several collections round London. This fine perennial thrives perfectly well almost anywhere, if planted in sandy peat.

— THE plant of *Disa grandiflora* alluded to the other day by one of our contemporaries as having been "grown and flowered out of doors," was, we are informed, grown in a house until about two months ago, when it was placed out of doors in a sheltered position.

— WE understand that Lord and Lady Holmesdale have directed their beautiful grounds at Linton Park, Staplehurst, Kent, to be thrown open to the public on Tuesday and Friday in each week, commencing on the 9th instant, a boon which, we are sure, will be duly appreciated.

— THE weight of tea consumed in this country last year was 55,090 tons 2 cwt. 65 lbs., and the average quantity consumed by each person was about 4 pounds. The average price of the tea, exclusive of 6d. per pound duty, was 1s. 4½d. It is stated that the price of tea has never been so low since 1856.

— Two rare and pretty hardy plants, introduced by Mr. Maw, are now blooming in the Kew collection: viz., *Salvia taraxacifolia* and *Linaria villosa*. The latter is like the better known *L. origanifolia* in habit, and its flowers, which are freely produced, are of the same colour. It is a first-class rock plant.

— ONE of the best hardy aquatic plants in flower at the present time is the North American Pickerel Weed (*Pontederia cordata*), a plant by no means so often met with as it deserves to be. It produces a stout spike of handsome sky-blue flowers, from 1½ to 2 feet high. No ornamental water should be without this charming aquatic, which should, however, have a place near its margin.

— AT a meeting of the Metropolitan Board of Works, the other day, a letter was read from Mr. W. H. Smith, M.P., offering twenty wooden seats to the Board, to be placed along the Victoria Embankment for the use of the public. He was willing to leave the choice of the seats to the engineer of the Board, but wished them placed there as soon as possible.

— ONE of the most conspicuous objects to be seen now near the Albert Gate, in Hyde Park, is a mass of plants of the coral tree (*Erythrina*), nearly every one of which, notwithstanding the very unfavourable season we have had for such plants, has produced spikes of showy scarlet blooms, and whether seen from Rotten Row or from a walk which passes near the bed, they look equally attractive and striking.

— WE again call attention to the hideous little mud wall-like edgings to the flower beds along Piccadilly and in many other parts of the London parks. We had some hope that by this time the outer line of plants would have fallen over and hidden them, but this is rarely the case. The miniature mud walls are all cracked now. It is the most ridiculous and offensive innovation ever made.

— AN experiment lately made with paraffine for the purpose of testing its power to keep birds from eating seeds when sown, proved so far successful that, of a handful of radish seed soaked in the oil for fifteen minutes and then sown, not a seed appeared to have been taken, as all came up freely, and no protection was afforded, although birds were very abundant. American blight may be entirely destroyed, it is said, by an application of the oil. Paraffine may be safely used upon hard wood, but not so upon wood that is green and tender.

— IR ever vegetarianism had a good chance, says the *Telegraph*, it is at the present time. Matters are going on so seriously as regards flesh meat that we are likely to be driven into a botanical diet, whether we like it or not, and in spite of all personal and physiological objections. What with the dearness of coal and the costliness of meat, there never was a period when the enthusiasts for salad had such a noble opportunity for converting us to *herbivori*. Certainly we must economise if we are to remain carnivorous, and we advise housewives to obtain the receipts for *pillau*s and *kabob*s, and make these Mussulman dishes British. With a mere scrap of flesh, but plenty of rice and seasoning, the frugal Mahometan cooks a smoking *pillau*, or an appetising *kabob*, which costs next to nothing, and yet nourishes bravely. Our housekeepers must imitate him or fall back on Australian tins, for joints of fresh meat threaten to be soon mere curiosities.

— PART of Sardinia is covered by immense clouds of locusts. It is impossible to describe the damage done to corn, vegetables, and vines; the desolation is general; the air, the fountains, and the rivers are infested, and exhale an abominable smell.

— A VERY severe hailstorm passed over Deptford last Friday night. It completely riddled the leaves of French Beans, Beet, Mangold, and other brittle-leaved crops in the market gardens of the district.

— IF any visitor to London wishes to see the worst example of avenue planting that any capital in the world can show, let him look at the Mall in St. James's Park. Limes withering in July, dying elms and unfiled blanks are the objects that will meet his view.

— THE historical tree, known in Mexico as the "arbor tristis," under which Fernand Cortez sat and wept upon the memorable night when the discord and mutinous spirit of his companions had destroyed the fruit of all his previous efforts, was recently smeared with tar and petroleni and set on fire.

— A NEW kind of grape is being grown in America, concerning which the editor of the *American* says, "The skins are useful for umbrella covers." We hope no time will be lost in introducing into England a fruit which would be found so peculiarly fitted for our climate this summer.

— A PLANT of *Michauxia campauloides*, which is said by some to be a biennial, is now blooming for the third year in succession in Mr. Barr's trial ground at Tooting. It bloomed two seasons in the position in which it was raised from seed; last spring it was moved to where it is now flowering.

— THE forest fires of California have burned thousands of acres of woodland and the houses on several ranches. At night they can be seen fifty miles away. In the perfectly dry summer climate of California the giant trees burn rapidly; frequently by the roadsides one sees a prostrate monarch of the wood one line of fire.

— NEARLY all the essences employed in perfumery are of European production. England produces lavender and peppermint largely. At Nimes, attention is given to rosemary, thyme, and lavender. Nice makes violet its speciality. Cannes extracts the essences of the rose, the yellow acacia, the jasmine, and neroli. Sicily furnishes citron and orange; Italy, iris and bergamot.

— THERE is now in flower in the Hale Farm Nurseries, at Tottenham, one of the finest specimens of *Campanula pyramidalis* we ever remember to have seen. It has more than fifty spikes of bloom ornamented with some thousands of flowers, the spikes standing erect and at regular distances from each other. It is about twelve feet in circumference, and is certainly a magnificent specimen of this noble bell-flower.

— ARTEMISIA ANETHIFOLIA, one of the most graceful herbaceous perennials, as far as habit is concerned, that we know of, may now be seen in flower in the herbaceous department of the Royal Gardens, Kew. The plant is five feet or more in height, and the stems are thickly clothed with finely-divided leaves from the base upwards, while the flowers are produced in a noble panicle nearly two feet in length. In gracefulness of outline, this *Artemisia* will bear favourable comparison with the shrubby *Tamarix*es.

— THE *Victoria regia* at Kew is now finely in bloom, and promises to furnish its glorious flowers for a long time to come. It has already produced a dozen fine blooms, one generally appearing every alternate day. The plant has sixteen fine leaves, the largest of which is a little over six feet in diameter. It is to be regretted that the tank in which this noble plant is growing is much too small for the proper development of the leaves. At present the latter are a good deal confined for room, and are not seen nearly to so much advantage as they would be if the tank was twice the size it is.

— AT a meeting of a committee of horticulturists and botanists held in the rooms of the Royal Horticultural Society at South Kensington on Wednesday last, for the purpose of discussing the recently issued Treasury Minute relating to the management of the Royal Gardens, Kew, a resolution was passed in which grave doubts were expressed whether the fourfold division of responsibility, laid down in the Treasury Minute, in question, is likely to secure to the full the harmonious co-operation of the several officials. The committee were also of opinion that to put the pleasure grounds under different management from that of the rest of the scientific departments of the gardens was likely to be injurious to the interests of horticultural and arboricultural science. The committee regretted, moreover, to find that there was no direct provision made in the Treasury Minute for securing to the Director, in case of need, the services of an engineer specially versed in the management of hot-water apparatus as applied to horticultural purposes.

THE SIX OF SPADES.

CHAPTER XVIII.

Mr. Chiswick on Bedding-out (continued).

THERE are three seasons and three systems of bedding-out, the winter, the spring, and the summer.

If we regard winter bedding-out under the most auspicious circumstances, when the atmosphere exhilarates, and our digestion is good, and our debts are few, we may possibly derive from it about as much amusement as from a third or fourth rate farce; but if we criticise it severely after unpleasant letters, or a pill, or when the wind is in the east, we can only speak of it as the Attorney-General spoke of the Tichborne Claimant, and denounce it as an impostor, a humbug, and a sham. Beds of baby evergreens, new-born hollies, infant aucubas, tiny junipers, and the like, edged with variegated ivies, arabis, &c., with most of the variegation washed and frozen out of them—these, as they peep out of the snow, like a lot of black pins in a white pincushion, evoke the gardener's ire, not only as an insult to his art, but as the abortive attempt of an insatiate greediness to get more than generous Nature will give. For my own part, I can only think of two exceptional cases in which these feeble failures, dignified by the name of winter bedding-out, might be benevolently excused. They might be introduced into the garden of a retired nurseryman, superannuated and in his dotage, as soothing reminiscences of early life, or mamma might have a bed of them in front of the nursery window, and point to them, when reading the voyages of Gulliver, as charming illustrations of the forest scenery of Lilliput. "They be for children," as Lord Bacon said of yew trees clipped into dolphins and peacocks; and I remember an instance in which children made a striking and serio-comic use of them.

I was contemplating the only attempt which I ever made to realize the meek, modest, little idea of transforming winter into summer, and of breaking in the garden committed to my charge the annual sabbath of its rest—and I was thinking what a dreary disappointment it was, when my attention was drawn to the altered appearance of a bed, in which a large number of juvenile Irish yews were arranged with a dreadful uniformity. Little mounds had been raised here and there among them, and a large white wooden "tally," taken from the potting shed, was inserted at the head of each. On a closer scrutiny, the beak of a defunct robin was observable rising out of one of these small hillocks, while from another the corpse of an ancient doll exhibited its toeless foot; and my conjecture as to the meaning and intention of these arrangements was speedily verified by a sweet little voice, which said, "Oh, please, Mr. Tissick, me, and Blanche, and Bertie have been playing at Cementerry, and Victoria Eugenie would not go into her coffin (a cigar box), and Bertie went and got his night-gown, and was going, you know, to be a clergyman, but Blanche said pa would not like it, and so we gave it up."*

And I also gave up playing at Spring. I saw that Winter, like an honest, handsome, old gentleman, disdained to dye his silvery beard and to act the dandy with a flower in his coat. I broke up my exhibition of dwarfs and pigmies, and distributed them in the shrubberies and borders. I parted with my magnificent collection of chromo-lithographs—that is to say, I removed in a wheelbarrow my walks, composed of coloured stones and shells, of brick dust, tile dust, coal dust, cockles, gypsum, and other cheerful rubbish. If, I asked myself, we

* Here I must tell a couple of authentic histories concerning dolls, in the belief that they will amuse the British public as they amused me. A six-year-old child, the son of the village schoolmaster, left his mother's side during the baptism of an infant in the church here, and had made some progress towards the font, when he was missed, pursued, and captured. Subsequently questioned as to his motive, he produced from his pockets two very dirty dolls, negroes in complexion and in scant costume also, and informed his parents, "he was going to take 'em to Mister Rennuds" (during my father's lifetime I was known in the parish as "Mr. Reynolds") "to be listened." Anecdote No. 2, is this:—Two wee lassies, aged five and six, were playing in a room with their dolls, and their mother, at her writing desk, was listening to their talk. The dolls were taken to various imaginary entertainments, walks, rides, drives, visits, and parties, and at last they were taken to church. "Now, dear, will you sit in this pew?" said one; "and will you, dear, sit in this pew?" said the other. Whereupon the mother saw an opportunity of improving the occasion, and interposed with the remark, "We don't have pews, you know, in our church; the seats are free and open to all, because all are equal there." And one of the little playmates immediately looked up and said, "Oh, yes, dear ma, but just now we're playing at very Low Church indeed!"

once admit this tea-garden trumpery, where are we to stop? I have seen, in the grounds of a suburban drinking-house, an *Araucaria imbricata* done in cast-iron, and painted appropriately a hottle-green. What if the idea should spread? What if somebody, with "no end of tin" and no beginning of taste, should "go in," regardless of expense, for a metallic winter garden, electro-plated Silver Hollies, Gold-leaf Yews, and real Copper Beeches? Why limit the collection to hardy shrubs and trees? Why not a Battersea Park at Christmas? Why not all the beautiful foliage of the stove? Why not *Alocasia metallica* in real bronze? Nay, why foliage only? Why not flowers and fruits? Why not purple Grapes, and blushing Peaches, and all the glowing splendour of August, defying 20° of frost?

Seriously, there is but one legitimate winter garden, and that no doubt an enjoyable luxury to those who can afford it—I mean under glass. But why should we crave it? Though we had neither greenhouse nor stove, we might be well content to rest with our plants and trees; to rest and be thankful for the past, to rest and be hopeful for the future. Some, of course, will say, "Ye are idle, ye are idle. You gardeners are always resting on your spades, always sitting under your vines and fig trees, instead of pruning and thinning." We need not make answer for ourselves. All who possess a garden and know anything about it, know this also, that never in the history of horticulture was so much required, and so much realised, from the gardener. For example, there is spring bedding-out, in my eyes by far the most attractive feature of modern horticulture. The most beautiful because the most natural; gladdening our hearts with a new happiness and with new hopes, just when Nature herself awakes in

"The delicious trouble of the spring,"

when the sap is rising in the branches on which the thrushes sing, and the child finds the first violet—blue-eyed and sweet as childhood itself—upon the sunny, southern bank, or comes tottering into the broad, green woodland "ride," holding up a primrose in its tiny fist triumphantly, as one to whom had just been given the first prize for a hand-bouquet. Then it is that the gardener's art, the art

"Which does mend Nature; change it rather: but
The art itself is Nature,"

changes and mends most successfully that which the first gardener marred and disfigured, because it is then most in union with Nature, assisting, developing, obeying, copying, as a loving, reverent disciple, and not dictating nor innovating, as a proud and omniscient lord. In a spring garden we "change and mend" only by multiplication, and by such improvement, or rather restoration, as vigilant care and cultural art can give. All our charming varieties of *Viola*, and *Primula*, and *Myosotis*, and *Anemone*, and *Erica*, for example, are collected and cherished there, when the first Primrose and Violet (as I have said), the Forget-me-not, and Wind-flower, and Wild Heath, come forth in their season, upon bank and mountain, in their woodland and moorland homes. The wild bulbs in their habitations (what time the Nottingham meadows are empurpled by their *Crocus* bloom) break forth into beauty with ours. The flowers in a spring garden look at home and happy. They know, as old friends, that they are welcome, and they smile their thanks. They are not as dainty and magnificent swells, who have been delicately nurtured (under glass), who seem too grand for their surroundings (as some brother in the Guards on furlough in his village home), and who will leave us, if foul weather come.

Then consider the diversity of colour, form, and combination which is found among these several flowers. Let us imagine that the winter is past, and that we survey their bright charms once more. Let us ask the beneficent fairy, who changed a pumpkin into a chariot to convey Cinderella to the ball, to transform one of those huge gourds which adorn our club-room into an omnibus, and bid Faucy drive us to—Spring Gardens.

(To be continued.)

S. R. H.

A FINE specimen of *Lilium speciosum splendidum* was exhibited at South Kensington the other day by G. F. Wilson, Esq. This long-stalked kind is one of the very best of what are known as Japan lilies.

THE INDOOR GARDEN.

EUCCHARIS AMAZONICA.

So rapidly has this noble stove plant grown in the estimation of the plant-growing public, that it is already almost as indispensable to the stove collection as is the lily of the valley and the white camellia to the houquet-maker. Indeed, the Eucharis bids fair to rival either of these, even with the Covent Garden people, and it is very extensively used among cut flowers. For room, stove, and, in the summer, conservatory decoration, it is equally valuable. To this we have to add that the best plants of it ever shown were grown by Mr. Howard, gardener at Bedford Hill, Balham, and that his success resulted from heavy waterings occasionally with mild liquid manure, a genial stove temperature, and repeatedly syringing them when in a state of

The Leaves of Drosera.—M. Ziegler has contributed to the Académie des Sciences of Paris (*Comptes Rendus*, May 6th) a series of observations on the irritability of the leaves of the sundew (*Drosera*). He finds that the hairs on the leaves exude from their extremity a small drop of glue, by which insects are caught. After an insect becomes attached, the exterior threads bend over it, covering it like the fingers of a hand, and do not straighten again till some days after, when a fresh drop exudes for a fresh prey. Albuminoid animal substances, if held for a moment between the fingers, acquire the property of making the hairs of the *Drosera* contract; except by contact with a living animal these substances exert no action on the hairs; and they lose their singular property by being repeatedly moistened with distilled water and dried each time in a water bath. In order to prove that the contraction of the hairs is not caused by animal heat, the substance was cooled before placing it on the leaf. The sensitiveness of the hairs disappears after repeated applications of the albuminoid substance, and their properties then appear to become reversed, showing similar sensitiveness to sulphate of quinine, which again restores them to their original condition of sensi-

EUCCHARIS AMAZONICA.

(From a Photograph of a Plant grown by Mr. Howard, of Balham.)

growth. It is another illustration of the fact, that cultivators generally have a poor idea of the true requirements of plants as regards moisture at the root when in a growing state. The splendid specimens we allude to, like other things grown by the same skilful cultivator, were not, when in want of water, simply watered once, but the first was considered merely a preliminary dose, and two others given. The fact is that, instead of the common statement made so repeatedly in the gardening journals, that most plants perish from over-watering, being true, the opposite is the case. Most pot plants that die perish from insufficient watering. Let it not be inferred from this that we recommend frequent waterings; one thorough one will save a dozen dribblings such as gardeners too often give, and therefore save time, and be far more effective and wholesome for the plants. The noble specimen, of which we now give an illustration, is engraved for us from a photograph of one of Mr. Howard's plants.

tiveness to insects after applications for a sufficient length of time. In all cases the contraction of the hairs is slow, commencing visibly in about a quarter of an hour, and is often not completed till after several hours.

Horticultural Vaporizer.—I am not acquainted with an apparatus that more effectually and economically distributes blight-destroying mixtures than the vaporizer of which you have given a representation at p. 84. The liquid mixture can be directed and precipitated with precision and effect upon any part of a plant infested with insects. A sulphurator constructed on the same principle throws little puffs of sulphur without waste upon mildewed leaves, and this also is a cheap and handy contrivance, which I have used with advantage.—W. INGRAM, *Belvoir*.

Primula denticulata.—I have had beautiful specimens of this really pretty plant, and I would recommend all who love Primulas to grow it extensively. If your plants are young, let them be potted in a mixture of half turfy loam, quarter sharp sand and quarter decayed leaf soil; keep them all summer in the shady part of a cold pit or frame. In autumn let them be protected from rain, and winter them in the warm end of a greenhouse. In February they will show flowers in abundance, and will keep in beauty for three or four months at a time; they do not seem to like cold winds or draughts, and therefore should not be exposed to them.—W. Stevenson.

THE FRUIT GARDEN.

FRUIT ON HOUSES.

CHOICE fruits are never better than when freshly gathered ripe from the trees, and this desideratum might be secured by the owners of even moderate-sized, garden-surrounded, or partly-surrounded houses, were their available walls and roofs covered with suitable descriptions of fruit trees. In making a selection for training over dwelling-houses and their associated buildings, due care should be had to combine the ornamental with the useful, by choosing only such kinds as are decided and showy in the colours of their fruits.

The grape vine is, and will ever continue to be, a favourite for growing on house walls, where the climate is suitable for perfecting its luscious clusters; but except in the southern portions of our island it can only be looked upon as an ornamental climber; although in more northern districts, where no vineries exist on the premises, a few of the most distinct foliaged sorts should always be grown in the warmest exposures for the garnishing of fruit dishes; and if the very earliest of these are selected, such as Miller's Burgundy, Parsley-leaved, Muscadine, Red Chasselas, Black July, Grove-end Sweet Water, July Frontignan, &c., ripe grapes might occasionally be gathered in remarkably warm seasons.

Among apples the Red Astrachan, Old Golden Pippin, Fearn's Pippin, Striped Juneating, and Red Quarrenden, will fairly represent the most conspicuous colours; and if many kinds of these, or most others, are wanted in small space they may be grafted or budded so as to have only a branch or part of a branch of each.

Pears generally present less showy surfaces than apples, yet among them are a few with really gay exteriors, such as the Forelle or Trout Pear, Louise Boume of Jersey, Seckle, and some others; while the less striking Jargonelle and the Marie Louise have acquired a reputation which insures their not being overlooked.

Among plums the yellowish colours and the light reds produce a more effective display than the greens and the dull dark coloured sorts; the White Magnum Bonum and the Golden Gage are good representatives of the first; the Victoria and Coe's Late Red, of the second; while the Greengage and the Old Orleans may be considered fair examples of the last two.

Cherries are of all fruits perhaps the most generally suitable for house-wall training, some of them being adapted for every exposure, and capable of perfecting even their deepest colours in the most sunless aspects; further, they can be had in perfection from the ripening of the May Duke and Belle d'Orleans in early June to that of the Belle Agathe and Rival in September and October, while their glossy surfaces exhibit all shades of colouring, from the whitish yellow of the White Heart and the marbled pale yellow of the Bigarreau Napoleon, through the bright reds of the Kentish and Carnation, to the deep purple and jetty black of the Black Eagle, Black Heart, and others.

Apricots, so conspicuous in spring from their being the earliest flowering of fruit trees, are scarcely less so for the rich orange of their ripening fruit in summer and autumn, commencing with that of the Red Masculine in July, and ending in September or the beginning of October with the well-known Moorpark and one or two others.

Figs, which can only be eaten in perfection when just plucked from the trees, may be ripened in succession for fully two months from the end of July, on southerly exposed walls in most districts, under an altitude of five hundred feet; and, independently of their rich and wholesome fruit, their characteristic luxuriant foliage should insure for them more general cultivation.

Peaches and Nectarines are more select in their choice of soil and situation than any of the fore-mentioned fruits, but, wherever circumstances are favourable to their growth, neither should be omitted; and if the large-flowered varieties are selected, the beauty of their spring blossom will, in general estimation, be scarcely surpassed by the chaste colouring and exquisite delicacy of their fruit in autumn.

A great objection to the more general cultivation of fruit is, that it tempts depredators to break in and destroy not only the trees in their hurried abstraction of it, but also to trample and injure the neighbouring flower-beds, plants, and ground. These objections apply with most force to small residences in and near towns; and often, in consequence of the disappointment and vexation caused thereby, have owners of wall fruit-trees been led to eradicate them, either leaving the walls bare or covering them instead with merely ornamental plants. Nevertheless such objections are really nutenable, and can be remedied by combining the ornamental with the fruitful, so as to cover all the lower parts of the walls, which are within easy reach, with showy flowering and foliaged plants, and occupying the higher parts, as well as the roofs, with fruit; to effect which it is only necessary to bud or graft the trees at the required height on

the lower growing ornamental plants. Of course this budding or grafting can only be done within certain naturally assigned limits; but such limits are considerably wider than is generally supposed, and are capable of still much farther extension if made the subject of careful practical experiment. To illustrate this more fully, the following may suffice:—

Having, some twenty years ago, a bare-walled gravel court in front of a partly plant-covered dwelling-house, it was resolved to clothe all the walls with vegetation; but the planting of fruit trees for this purpose being deemed inexpedient in consequence of the uninterrupted access which numerous labourers had to and through the court, a selection of ornamental plants was decided upon, among which were the after-mentioned, which were used as stocks. When they attained to sufficient size to allow of being operated upon at the height of the doors and lower window tops, apples of different kinds were grafted upon the showy semi-double Chinese crab (*Pyrus spectabilis*), and a variety of pears were "worked" upon the wild pear of Mount Sinai, as well as on the common quince, the double white, double scarlet, and the sub-evergreen Mexican hawthorns. All thrived remarkably well, the stocks being annually covered with their own flowers and foliage up to their junction with the grafts, which grew and fruited freely, till, in the severe winter of 1860-61, the Mexican hawthorn was killed by the intense frost, and a fine top of White Benrre pear which was upon it consequently perished. Among the old plants upon the dwelling-house was a White Magnum plum, in the form of a "rider," with gross-growing unfruitful centre branches; these were budded with Moorpark apricots, for which this plum proved to be an excellent stock, the buds taking, growing, and ultimately fruiting freely.

Of other ornamental stocks known to be suitable for fruit trees, the following may be mentioned:—For Apples—The profuse blooming *Pyrus floribunda*, the curious Japanese *P. Toringo*, several of the small fruited crabs, and the different variegated-leaved varieties of the *P. Malus*. For Pears—The snowy-leaved *Pyrus nivalis*, and other three or four allied hoary-leaved species, the variegated-leaved pear, white and yellow variegated, as well as the scarlet, and other showy flowering and fruiting varieties of the common hawthorn, and most, if not all, the ornamental species of *Crataegus*. When the quince is used, its lower portion might be made more ornamental by working its sides and spurs with the different varieties of *Cydonia japonica*, all of which take well upon it, and the pear is also known to grow on those more widely different species of *Pyrus*, the mountain ash, service berry, &c. For Plums—The variegated-leaved and double-flowered varieties of *Prunus domestica*, and the double-flowering sloe thorn, *P. spinosa fl. pleno*. For Cherries—The double-flowering cherry, double-blossomed gean, Fortune's pale bluish or rosy coloured double-flowering Japan cherry, the acubaspotted and variegated-leaved cherries, *Cerasus semperflorens*, *C. serrulata*, &c. For Apricots, Peaches, and Nectarines—the fore-mentioned plum stocks will answer if double wrought with the kinds best suited for the respective sorts. Almonds also make good stocks for the two latter, as doubtless would also the more robust varieties of double-flowering peaches.

Of probably suitable ornamental stocks for fruit-trees, a large number might be indicated as being deserving of trial. Thus the *Pyraecantha* and evergreen *Cotoneasters*, which work freely on the hawthorn, might be grafted upon it, and then with the pear. The quince is an excellent stock for that showy large-leaved evergreen, the *Photinia serrulata*; and were it in turn to support the quince, then in either of these cases wall pear trees might be made to present the anomalous incongruity of growing on evergreen basements. But this chapter of probabilities might be lengthened out indefinitely; and were anyone to take the trouble of thus doubly and triply interworking different kinds, many curious results might be achieved, and much more interesting knowledge derived as to the influence of the stock upon the graft, and *vice versa*, than we now possess.

As a rule, then, all spur-bearing strong-wooded growers, such as apples, pears, and the more robust cherries, should be regularly trained at about twelve inches apart, so as to correspond with the architectural outlines, and surround the door and window edges at regular distances of say six inches. These branches should be securely fastened to malleable iron loops previously inserted in the proper lines, and no driving or drawing of either loops or nails should be afterwards tolerated. The leading branches of kinds which bear upon their young wood should be secured in like manner, and their year-old fruit-bearing shoots held in position between them by small cross rods or wires. From the wall faces, the branches may be continued upwards over the slate or tile roofs, those on the first being held in their places by having small belts of tin or zinc bent over them, the ends being inserted under a slate on either side while on the latter they may be either secured to wires

fastened in the tile hollows, or by ties proceeding inwards under the tile overlaps to the laths. Late flowering fruits are most suitable for roof covering, as the blossoms are necessarily much exposed to early cold, and when the late spring frosts have been passed with safety, roof slopes are capable of producing apples, pears, and other fruits of surpassing beauty.—*Farmer.*

OUR FRUIT CROPS.

ADDITIONAL REPORTS.

Preston Hall, Maidstone, Kent.—All outdoor fruits are very scarce indeed in this locality. By chance you may hear of very small well-sheltered spots in which there are small crops, but they are wholly exceptions. The general report is either "very little or no fruit."—*W. BRADLEY.*

Redleaf, Penshurst, Kent.—As a general rule, outdoor fruit crops in this neighbourhood are all very much below the average; the exceptions are Cherries, which were pretty good, and Strawberries, which on high grounds were very good indeed, but on lower lying grounds very much cut up by frost in spring. Apples, except in isolated instances, are a total failure. Pears, very few. Apricots, one-tenth of a crop. Peaches, one-fourth. Plums, partial. Small fruits very thin.—*JOHN COX.*

Heckfield Place, Winchfield, Hants.—Of Apples we have here none. Pears are a good crop. Peaches and Apricots half a crop. Plums on walls a heavy crop, none on standards. Cherries of all kinds very thin. Strawberries a very heavy crop and fine. Raspberries very good. Currants, both black and red, very thin and blighted. Walnuts, none. Filberts, half a crop. In this district the Apple crop is a total failure, and in all other parts much below the average.—*W. WILDSMITH.*

Strathfieldsaye, Winchfield, Hants.—Out-of-door fruits in the gardens here, and, as far as I have seen, in the neighbourhood, are very scarce indeed. Of Apples I shall not have single fruits for bushels I have gathered in former years. Of Pears there are positively none on standards, but on walls, where protected, there may be about half a crop. Peaches and Apricots, though carefully covered with thick sheeting, are not more than a quarter of a crop, and the same remark applies to Cherries and Plums. Raspberries and Strawberries cropped well. Gooseberries and Currants I had none. I may add that the gardens are only a few feet above the level of the river Loddon, and we suffer very much from early and late frosts.—*JAMES BELL.*

Great Tew, Enstone, Oxfordshire.—Apples, Apricots, Peaches, and Nectarines are with us a total failure. Strawberries, Raspberries, black Currants, Cherries, Pears, and Plums are good crops; red and white Currants half a crop; Gooseberries a heavy crop; Nuts and Walnuts very few. Our orchard house, a lean-to 110 feet long by 18 feet wide, is heavily laden; the Peaches and Nectarines are very fine; our back wall is fifteen feet high, with standard Peaches and Nectarines trained against it; the pot plants are also well cropped, also the Pears and Apples in pots; this is now our sixth year of orchard-house work, and I can testify from our experience during that time that Pears and Apples are very far superior to those grown outside.—*A. MACPARLANE.*

The Deepdene, Dorking, Surrey.—We had abundance of bloom of all kinds in spring, but, with the exception of Pears, Gooseberries, and Strawberries, our fruit crops are very thin. With Apples a few trees are well cropped, on the rest there are none; they were attacked by a small grub or caterpillar, which destroyed the bloom wholesale. Of Pears we have a heavy crop, and plenty in the neighbourhood. Peaches and Nectarines very scarce, but the trees are making beautiful growth. Plums very scarce, none whatever on east and south walls, but a good number on west walls. Gooseberries abundant. Red and black Currants scarce, white very fine and a good crop. Strawberries have been a very fine crop, although some of the first blooms were destroyed by frost in May. Apricots none. Figs a fair crop. Cherries thin, and much damaged by blight. Grapes are a good crop; in fine seasons they colour well in this locality.—*Muscadines assuming a beautiful golden hue. Cob Nuts plentiful. Walnuts scarce. Altogether a poor fruit year, but a splendid one for vegetables on light soils.—JOHN BURNETT.*

Lambton Castle, Fence Houses, Durham.—With us here Apricots are a failure; the blossom was killed by late frosts. Of some kinds of Apples there is a fair crop, but others are a failure. Pears, plentiful on old standards; on young trees a medium crop. Plums moderate. Strawberries good and plentiful. Cherries moderate; Morellos very good. Peaches and Nectarines very thin. Small fruits abundant.—*J. HUNTER.*

Castle Gardens, Arundel, Sussex.—Our fruit crop this year is very thin; I have, however, a splendid crop of Pears. Apples, scarce; also Peaches, Nectarines, and Apricots. I have good crops of small fruit, though not so abundant as in other years. Everywhere in Sussex Apples are scarce.—*J. W.*

Luton Hoo Park, Luton, Bedfordshire.—Apples with us are almost a failure. Apricots we have none. Red Currants a very light crop, black a very heavy crop. Our Nectarine and Peach trees are not yet in a bearing state. Of Strawberries we had a fair crop. Cherries also a fair crop of Morellos; trees not in a good state. Gooseberries and Raspberries a very light crop. Pears a good crop on walls, very few on pyramids. Plums a fair crop on walls. Our Fig and Filbert trees are not yet in a bearing state.—*R. BUDD.*

Killerton Gardens, near Exeter, Devon.—The following is the state of the fruit crops in this neighbourhood, viz.:—Peaches, Nectarines, and Apricots, very few; trees looking well. Plums, very few. Cherries, a moderate crop; trees much blighted. Pears, a moderate quantity on some trees on walls; pyramids set very thickly, but all the fruit dropped, owing to the cold. Apples, very scarce; also the same in orchards throughout the neighbourhood. Red, white, and black Currants, very scarce. Gooseberries and Raspberries, both good crops. Strawberries, moderate; first blooms killed by frost.—*JOHN GARLAND.*

Bower Ashton, Bristol, Somerset.—The following is a fair and impartial account of the fruit crops of a considerable part of the counties of Somerset and Gloucester:—Of Apples and Pears we have scarcely any except on some trees (a good many) which were removed from one part of the garden to another in the autumn of 1870—a fact which points to the advantage of occasional removals or root pruning; on these there is a very fair crop, and the trees are healthy and clean. Peaches are almost a complete failure, and of those left few will be of any size. Plums, none on standards or walls; Apricots none; Figs very few. As to Cherries we had at one time a fair prospect of a crop, but owing to cold, frosty nights, the blooms did not set properly, and nearly all fell off. Gooseberries, Raspberries, and Currants a partial crop, but good and clean. Strawberries not half a crop, and not good in flavour.—*W. DODDS.*

Cleavelands, Lyme Regis, Dorset.—Fruit crops in this neighbourhood are generally deficient. Of Peaches and Nectarines there are scarcely any out of doors; of Apricots scarcely any are grown in this neighbourhood, owing to the trees being so short-lived; of Plums we have a very short crop. Bnsh fruits are deficient; Gooseberries below average; Raspberries fair crop; Currants had; the Strawberry crop has been abundant and good; Pears almost a failure; and in Apple orchards, of which there is a large area in this locality, there are scarcely any fruit, consequently very little cider will be made this year.—*HENRY MUNRO.*

Castle Ashby, Northamptonshire.—We have more than average crops of Pears upon wall trees, but nothing at all upon standards or on any form of trained Pear trees except those on walls. Of Apples and Plums we have none. Cherries, a few Morellos. Apricots, none; the trees were well set with fruit, but it was destroyed by frost on the morning of the 20th of April, when we had 11°. Peaches and Nectarines, very few; mostly destroyed by April frost. Red, black, and white Currants, &c., a few. Gooseberries, a medium crop. Strawberries, very light. Raspberries, a good crop. I have a fine lot of pyramidal-trained Pear trees which bloomed beautifully, but the blossoms were all destroyed by the spring frosts.—*GEORGE BEECH.*

Aswarby Park, Folkingham, Lincolnshire.—Apricots are here only about half a crop; fruit, very fine. Apples, a quarter of a crop; fruit promises to be small. Peaches, on some trees, are a full crop, while on others there are none. Nectarines, the same. All standard Pear trees here are bearing a full crop, and the fruit promises to be clean and good; Pear trees on walls, about half a crop. Plum trees, both standard and on walls, a failure. Early Cherries a failure; Morellos, a full crop, and fruit good. Strawberries, a full crop; fruit large and of good flavour. Raspberries, a full crop, fruit large. Black currants, a fair crop, but red kinds a failure. Gooseberries a good crop.—*RICHARD NISBET.*

Croxteth, Liverpool, Lancashire.—Our outdoor fruit crops are very meagre. Apples are a total failure; Pears a scarce crop, and the foliage very much cut up; Peaches and Nectarines are a failure; Cherries a good crop, and good-sized fruit; Currants and Gooseberries are a fair crop; Strawberries a fair crop, but the fruit is very small. The fine weather we had in February and the severe frosts and winds in March and April were very much against outdoor fruits, and the heavy rains while the Strawberries were in bloom, and after the crop was ripe, spoiled our best fruit.—*JOHN BISSET.*

THE KUMQUAT.

(CITRUS JAPONICA.)

THE following information respecting this interesting and, when in fruit, pretty species of orange was communicated to the Royal Horticultural Society by Mr. R. Fortune:—"I found it cultivated over a large tract of country in China, but it was evidently most at home in the mere temperate parts—for example, in the islands of the Chusan Archipelago and on the mainland in the same latitude. Here large plantations were met with on the lower slopes of the hills, and very beautiful they appeared in autumn, winter, and spring, when the plants were covered with their golden-coloured fruit and deep green leaves. The fruit is much liked by the natives, who eat the skin as well as the pulp. Its chief value, however, is when used as a preserve. A large quantity is exported annually to Europe and America in China jars, preserved and sent home in nearly the same way as the better known China ginger is sent. In this country, however, we must look at the Kumquat as an ornamental plant only; and I really think that if our gardeners would set about its cultivation in the right way, they would find it easy to grow, and it would amply repay them by being one of the most ornamental plants for winter decoration. In the country where the Kumquat is found in the highest perfection, the common orange will not survive the winters; and, on the other hand, the Kumquat, when cultivated in the south of China, does not succeed, although the common orange is found there in the greatest perfection. The cold winters of the north, which kill the orange, are favourable to the constitution of the Kumquat. Both plants require warm summers; indeed, the northern summer is frequently hotter than the southern one. A hot summer temperature, varying from 80° to 100° (Fahr.), is necessary to enable the Kumquat to form its growth and ripen its new wood. In winter it will bear without injury from 10° to 15° of frost, and perhaps even a lower temperature than this. If we wish to have it in high health and vigour, we must keep it cold and rather dry in winter. During its season of growth in summer it ought to have a liberal supply of water, and a temperature of from 80° to 100°, and this heat should be kept up well even in autumn, in order that the young wood may be well ripened."

SUMMER PRUNING OF THE VINE.

THE system of stopping or summer pruning the vine now adopted everywhere throughout these islands, is radically wrong and injurious. We stop a joint or two beyond the bunch, and this is recommended in our latest and best treatises on vine-growing. This, it is argued, throws all the "strength into the bunch." Common observation of the growth of the vine would teach one to doubt the soundness of the principle; reason and the best practice prove that it is utterly needless and injurious. The noblest vine that we know of within easy reach of London is in Kay's nursery at Finchley. Taking size of tree—it is worthy of the name—combined with size and quality of bunch and berry, it is far before either the Cumberland Ledge or the Hampton Court vines. A vine is in its growing power like one of these great tropical climbers, or the gigantic sea-weed (*Macrocystis*) that attains a length of from two to six hundred yards; for, even as we cut and mutilate the vine, we find very large specimens here and there. Given a congenial temperature and good soil, it would be difficult to say how large a vine would not grow. But the merit is not in the length of stem or multitude of leaves; no big vine is worthy of the admiration of intelligent cultivators which is not as remarkable for the regular production of noble bunches and first-rate berries as for mere wood. We repeat, the Finchley vine is a far more creditable specimen than any large vine we have ever seen, and we draw attention to it now to illustrate a subject in which numbers of our readers are at present interested—the stopping of the shoots of their vines.

Instead of the sheets of this noble vine being stepped at one or two joints above the bunch, as recommended by the before-mentioned authorities, they are, on an average, stopped at five or six joints above the bunch. In fact, they can hardly be said to be stopped at all in the ordinary sense. The vine grows so strongly beyond the bunch that the usual stopping of gardens amounts to sharp cutting back or mutilation. By allowing them to make four, five, or six joints above the bunch, as at Finchley, the natural, or nearly the natural, amount of growth has liberty to develop, and the stopping becomes a mere pinching off of the half-exhausted and fragile apex. With the common mode of stopping there is usually much supplementary stopping and pinching, as no sooner are the sheets cut off beyond the bunches than the life-vigour we try to repress by stopping breaks forth again in the form of secondary shoots, which are, as a rule, mercilessly removed. This does not take place, or at least in but a very minor degree, where a more natural

development is allowed at first, and time is not lost in needless mutilation. Besides this, the leaves that cover the roof of the house are nearly all these that have unfolded early, and therefore become mere thoroughly matured. It is right to assume that it is not without need that the leaves roll out so rapidly in spring; secondary growths are the exceptions. The rapid way in which many of our trees lengthen their shoots and form leaves we all know. The generally adopted plan of stopping the vine tends directly to the encouragement of secondary growths. The shoots and leaves should be allowed to fill every portion of roof space in any house devoted to them as soon after the start of vegetation as they can attain to this length. In many places it may be that vines are planted so thickly that, if allowed to grow so long beyond the bunch, they would be confused; but in every case the cultivator may shake himself free from the notion that he is bound to step every shoot at one or two joints beyond the bunch, and do his best to secure free, natural, and healthy development above as well as below that point. Depend upon it, the bunches will be none the worse for an abundant stream of sap coursing past them—not going to rival bunches, but to leaves.

Colouring Pears.—To cause pears to colour handsomely, the *Agriculturist* says "all that is necessary is to spread a blanket on the floor of a cool room, and then to place the fruits thinly and evenly on the blanket. A second blanket must be spread over them, and in a short time the good effects of this treatment, in the way of colour, will be apparent. Pears perfected in this manner, rarely have the mealiness of their naturally ripened companions; nor do they prematurely decay at the core, as when left on the trees." This of course implies that they must be picked in advance of ripening on the tree, the time for which is partly indicated by a slight change of colour, and partly by a readiness to part from the stem when gently lifted, so that some strain is made at the point of junction.

Root Fibres.—When anyone who is about to plant fruit trees examines the roots as he receives them from the nurseryman, he finds some large, some medium-sized, and some small. The large and medium-sized should be shortened—that is well understood. Let me add that they should be shortened rigorously, no split or bruised parts being allowed to remain. But what is to be done with the small fibres which issue from the large and medium-sized roots? Some writers and practical men make great account of them, and say that they should be scrupulously preserved. I was for a long time of the same opinion, but now I think differently. These fibres, destined to perish, should be entirely removed. They are in the way when dead, and, when living, impede the action of the large and medium-sized roots, which alone are capable of producing fresh roots strong enough to insure a successful re-rooting and vigorous growth to the plant; moreover they prevent the soil from coming into contact with the roots, which is an essential point. My opinion is founded on the experience which I have had with pears grafted on the quince. Those who are disposed to question it should make the experiment.—*J. Courtois*, in "*Revue Horticole*."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Orientation of Fruit Trees.—In *Les Mondes* we are told why some fruit trees in the open air are weak, contorted, and stunted. Their defects are due to the neglect of the precaution of placing them, when transplanted, as they had stood when in the nursery ground. It is the effort of these trees to recover their original orientation which causes their contorted appearance.

Fruit for the Roadside.—I wish our country gentlemen would consider how much may be done to make our roads more pleasant and beautiful by planting trees along them, if not continuously, at least in groups. The trees would not only be grateful shade in summer, but might break the force of the north-easter, 25° Fahr., in January. Fruit trees are often planted along the roadsides on the Continent—in many places near Geneva for example. Where the lanes are planted with tall scrub and low trees it would be very desirable to plant them with fruit trees instead. Grafted apple trees of good kinds are as cheap as common hardy trees; and surely, even if the fruit were to a great extent taken, it would be better to have trees which are at once beautiful and bear quantities of excellent food than the mixed rubbish that bears little even for the small birds.—*A. Dawson*.

Gathering late Pears.—Mr. John Garland, gardener at Killerton, a very successful pear-grower, in a paper read before the Devon and Exeter Horticultural and Botanical Society, says: "In reference to gathering pears, I always defer this for late sorts as late in the season as possible, that is, if the weather is mild and they do not drop off. I am convinced the later they are gathered the later they ripen, in proof of which I may say that Winter Nelis has usually ripened with me in November; I gathered them last year on November 5th, which is later than usual, and none of them have yet (December) ripened. I have had quite a succession from the same tree by gathering some two or three weeks earlier than others. We have generally a large supply of autumn pears, hence my desire to retard the ripening of later sorts."

Grapes in Bottles of Water.—The best kind of bottles for preserving grapes in water are those made of clear glass, of a size that would contain about a pint. In clear glass bottles, when the water, by means of evaporation and the small quantity sucked up by the bunches, has decreased, the deficiency can be easily seen and remedied. Champagne bottles would do for preserving a few dozen bunches, but they would be too large and clumsy to put in the racks where a large quantity of grapes are preserved. Pint porter or ale bottles do very well; I used them before I got clear glass bottles made for the purpose. The water in the bottles wants no changing, as it will remain perfectly sweet for three or four months, or longer, if some small pieces of charcoal are put in the bottom of the bottles. It only requires filling up now and then when it gets lower than the neck of the bottles.—*WILLIAM TILLEY*.

THE FLOWER GARDEN.

UHDEA BIPINNATIFIDA.

This subtropical plant is a native of Mexico, and is, as may be seen by our illustration, a very handsome-leaved one, and of a good habit. The leaves are of a slightly glaucous or silvery character. The plant is well suited for forming rich masses of foliage, not so tall, however, as those formed by such plants as the Ricinus or Ferdinanda; it may be seen in the London parks planted in large beds along with the Polymnia, Ricinus, Caenas, &c. We have seen it in a presentable condition when isolated on turf. It is easily propagated by cuttings taken from old plants kept in a cool stove, greenhouse, or pit during the winter months, and placed in heat to afford cuttings freely in early spring. Under ordinary cutting treatment

Uhdea bipinnatifida.

on hotbeds or in a moist warm propagating house, it grows as freely as could be desired, and may be planted out at the end of May or the beginning of June.

FERNS FOR BASKETS.

A MORE beautiful object I do not know for imparting grace and elegance to rooms, corridors, &c., than a well-grown basket of ferns, either suspended from the ceiling or from ornamental brackets in the walls. During the hot summer months the varying shades of green in their arching feathery fronds, impart an elegant and cool appearance; and when two or more sets of plants are grown for the purpose, so as to admit of frequent changes, the interesting features of this mode of room decoration are considerably enhanced. Amongst the best strong-growing ferns for large rooms are Polypodium aureum, Woodwardia radicans, and Aspidium exaltatum. Their long arching fronds have a grand appearance, especially when the rooms are artificially lighted. The bottom of the baskets should be covered with a few trailing sprays of Cissus discolor, hanging about in apparent negligence. This Cissus does well in baskets; short pieces of the old wood strike freely in early spring if taken off before growth commences. If the cuttings are put in in February, the growth of this plant is so rapid that nice young plants will be ready for filling baskets in April. Almost all the hardier kinds of stove and greenhouse ferns do well in baskets—not only those whose mode of growth naturally fits them for suspending, but many of the erect growers also; but the bottom of the basket should in all cases be covered with creeping or trailing plants, such as Panicum variegatum, Tradescantia zebrina, Isolepis gracilis, Lycopodiums, &c. The object should be to hide every wire of the basket, which should be made as plain and simple as possible. Highly elaborate and ornamental baskets are not required; they are more difficult to fill satisfactorily, and the projecting ornamental work to my mind seems out of place. Some time ago, when looking over a

lot of baskets in a shop, I made an observation to the preceding effect, but the dealer remarked that every man liked to bring into prominence his own handiwork. A plainly made basket, simple in shape, lined with green moss, and one or more plants planted in it according to the size, the bottom covered with creeping or trailing plants, which should be pegged in till the basket is covered, and then allowed to hang down negligently—this, according to my ideas, fulfils the conditions required in a tasteful basket of plants. Our baskets are home-made, and are generally circular in shape. A handy man after a little practice will make half-a-dozen to begin with in a few hours, and will soon be able to impart a certain amount of neatness to his work. As the wires are intended to be hid with moss and foliage, fine workmanship is unnecessary. We use two kinds of wire. A stout wire forms the framework of the basket, and is lashed together with a smaller wire; and when finished the whole is painted two coats to keep the wire from rusting. A file and a pair of pliers are all the tools required, and such work could be done on wet days. It is always best to fill a few new baskets every spring; there is thus always a lot of fresh young specimens coming on.—E. Hobday.

A LAWN POND.

I HAVE lately assisted in beautifying a "lawn pond," which has this summer done great justice to the pains bestowed upon it. The lawn is on the top of a hill, from which is a wide view of the surrounding country, and runs out from the house among glades of beautiful trees, limes, firs, and chestnuts. In one of these glades was originally a square pond, with low square turf banks, and no vegetation to speak of, except grass and the boughs of trees that dipped down towards the water. At length a lover of flowers introduced water lilies, and now they have spread in splendid masses across the pond. Next, bulrushes were introduced, which spread only too quickly; but their appearance is magnificent, and they crowd into a charming foreground at one end of the pond. The King-cup (*Caltha palustris*) was brought soon after, and forms a gay golden lining to the banks in the early spring. An expedition to some of the neighbouring damp ditches enabled us to procure a supply of Meadow-sweet (*Spiraea Ulmaria*), and the foamy heads of its flowers are now mixed with the tall grasses on the banks. The river Colne is about two miles distant, and two or three journeys resulted in plants of Willow-herb (*Epilobium hirsutum*), *E. angustifolium* (found on an old wall), *Scrophularia aquatica*, the Reed Poa (*P. aquatica*), a fine specimen of a Water-dock (*Rumex Hydrolapathum*), Marsh Carex (*C. paludosa*), Arrow-head (*Sagittaria sagittifolia*), purple Loose-strife (*Lythrum Salicaria*), Marsh Stachys (*S. palustris*), Branched Sparganium (*S. ramosum*), Water Veronica (*V. Anagallis*), simple Sparganium (*S. simplex*), common Skull-cap (*Scutellaria galericulata*), two kinds of Polygonum, Forget-me-nots, the Orange Balsam (*Impatiens fulva*), yellow Thalictrum or Meadow Rue (*T. flavum*), common Valerian, and Water Starwort. These were planted last year, and this year most of them are very flourishing, except the Orange Balsam, which seems to have disappeared, and the Arrow-head, which must be re-planted. A plant of *Osmunda regalis* was brought from North Wales and is doing well, and a little plot of Beech fern pegged into the bank close to the water's edge is fresh and lovely; close beside it grows the grass of Parnassus. The *Dresera retundifolia* was also brought from Wales. A little way out in the water stands one of our greatest treasures—the Sweet Cyperus, or Galingale (*C. longus*), doing very well, brought from a brook at the Lizard, Cornwall. The Cotton Sedge came also from Cornwall, and the Ivy-leaved Bell flower (*Campanula hederacea*). Some common Teazles were planted on one bank for the sake of their handsome appearance amongst the grasses and water plants. A wild rose-bush hangs its graceful branches into the water at one corner of the pond. We meet with some disappointments; but, on the whole, the plants have been very successful. We are careful to allow no mowing within some little distance of the banks. Live creatures abound. Little moor-hens run along the lily leaves, rabbits come out to feed on the lawn, and I regret to say, eat down a treasure occasionally in the pond. You can sit in the cool shade on a hot summer's day and listen to the splash of the fish, and hear overhead the gay laugh of the woodpecker and the clatter of squirrel's claws upon the bark of the fir-tree, while a harmless snake glides off into the bushes.

M. A. D.

Golden Veined Curled Dock.—This is the finest of all our native Docks, and is quite distinct from any other variegated hardy herbaceous plant in cultivation. I found it last year in a meadow in Buckinghamshire; the plant was quite young, so I dug it up, conveyed it carefully home, potted it, and gave it a start in a

cold frame. It grew away famously till towards the end of July, when it began to lose its variegation, and soon afterwards became altogether green. Being disappointed by this change in colour, I turned it out of the pot and threw it away. It, however, happened to fall at the bottom of a hedgerow, where it soon struck root, and there it remained till this spring. Having accidentally noticed it again coming up brighter than ever in its yellow livery, I lifted it carefully, potted it, and placed it in the greenhouse on a stage with a northern aspect. From that time it has retained its beautiful variegation, which consists of bright golden yellow veins spread over the entire surface of the foliage, rendering it about as handsome as one of the best of our Crotons. Last year it ripened seeds, but should these not reproduce variegated plants, it can be increased by means of division, at the rate of six young plants to each crown. I have seen many beautifully variegated forms of *Rumex obtusifolius*, *Acetosa*, and *Acetosella*, but they are all more or less inconstant in their markings; notwithstanding this, however, I believe that there are kinds in existence constant enough to render them worth cultivating.—WM. ELLIOTT, *Beechmont, Sydenham*.

Whence Come the Finest Roses?—I can assure Mr. Camm that I have grown, and hope to grow, much finer roses than those which he showed at Kensington and at the Crystal Palace, upon "the maiden briar"; and that, if he will appeal to our arboriculturists, he will find that the best blooms are gathered, as a rule, from the budding-ground. I will refer him to Mr. Cant, Mr. Turner, Mr. Keynes, Mr. Paul, and Mr. Cranston, and to the amateur who has most distinguished himself of late years, the Rev. E. N. Pochin. Some roses are as beautiful upon the *Mauetti* as upon the briar, e.g., *Baroness Rothschild*; but, again, I say, that as a rule the roses from the briar are the best; and I know that the authorities, whom I have mentioned, have proved this to be the case.—S. REYNOLDS HOLE.

A Good Garden Hedge.—*Berberis atro-purpurea* is said, in *Revue Horticole*, to form an effective and durable garden hedge. The plants should be set at an angle of about forty-five degrees, and four inches from each other; the stems, as they cross each other, being interwoven so as to form a sort of lattice-work with interstices of four inches across. As the plants grow they become naturally engrafted at the points of intersection, and present a solid and impenetrable fence. A hedge of this kind, kept to a height of about 3½ feet, requires no other care than that of one or two clippings in the year. A very pleasing addition is made to its appearance, by planting here and there among the *Berberis* a few Persian and other dwarf lilacs, clematis, honeysuckles, jasmines, and similar plants.

Variegated Veronica Chamædrys.—Variegated forms of *Veronica Chamædrys* are exceedingly useful in the spring flower garden or in select herbaceous borders. I have half-a-dozen kinds all differently variegated, but some of them are not sufficiently constant to make them suitable for general use. One variety, however, which has its young growth conspicuously variegated with creamy white, retains its variegation pretty well throughout the early part of the season, and will therefore be a welcome addition to our stock of dwarf variegated hardy plants used for margins of beds or borders in spring. As the summer advances it loses its variegation, but then it can be transferred to the reserve garden, and its place supplied with summer-flowering plants. It may be increased rapidly by means of division, and looks remarkably well on rockwork. The tints of variegation in this *Veronica* range from pure white to deep yellow.—WM. ELLIOTT, *Beechmont, Sydenham*.

A WHIRLWIND IN YORKSHIRE, AND ITS EFFECTS.

For several weeks back, scarcely a day has passed in this district without a thunderstorm, more or less severe, accompanied by perfect deluges of rain and violent gusts of wind, which culminated in a whirlwind on the 22nd of July, about a mile from the gardens here. Had we not seen its effects, we should not have believed it. It appears to have been a whirlwind and water-spout combined, as those who saw it describe it as having the appearance of a huge snake, whirling with erected crest and fearful speed across the country, and carrying with it branches of trees, hay, and debris of all descriptions. In a field on this estate, it seems to have been caught for a while, if I may so speak, and manifested its force and fury in a most extraordinary manner. This field is about three or four acres in extent, nearly circular, and, excepting a gap at one place, is surrounded by a belt of tall trees. The whirlwind appears to have entered by the gap, as it came across the district in this direction, doing much damage on its way, and, arrested by the belt of trees, it has torn round the field, uprooting or pulling up about a score of trees, and twisting off the limbs and branches of others in a remarkable manner, and carrying them along with it until it came to the gap again where it seems to have escaped, taking with it, just at last, the top of a hay-stack and part of the roof of a shed which was not protected by the trees. Several of the larger of the trees it seems to have caught by the top, and gathering up branches in its grasp, as one might gather the tops of a geranium in the hand, it has wrenched them clean off, leaving nothing but the stem of the tree and a few bare limbs. Off one birch tree, about nine inches

diameter in the stem, it has twisted the head about ten feet from the ground. Leaving this field, it has swept across a wheat field, in some places tearing the wheat out by the roots, in others just taking the ears off, and catching a large plane tree growing in the hedgerow, it has hurled it over with such force as to pull the tree entirely out of the ground, breaking every root, and leaving a large hole in the ground. The stem of this tree is about seven or eight feet in circumference. From here it can be traced for four or five miles across the country, but no further. What strikes one most in connection with this whirling column of air is its terrific force, considering the small area of its base, which does not seem to have been more than thirty or forty feet wide. The plane tree in the hedgerow has caught its full force, which must have been equal to some hundred horse power. The tree, one would imagine to have been partly pulled or twisted out by the root. Some of the branches have been torn off and carried away, but the trees on each side, growing in the same line, and only a few paces off, are untouched, showing that the gust has passed through between them. The same local effects are observable along its whole track. J. S., *Wortley*.

THE LIBRARY.

THE FLORE DES SERRES.

AFTER waiting over eighteen months, we have at last received the first three parts of the nineteenth volume of this beautiful work, which M. Van Houtte had promised to those who subscribed for it in advance on the 1st of December, 1870. This triple number contains, besides numerous woodcuts, twenty beautifully-executed coloured plates of floral subjects, and three double-coloured plates of Pears. The floral plates may be summarily described as follows:—1 and 2, a most beautifully and delicately shaded double plate of a somewhat difficult plant to figure really accurately, viz., the *Echeveria pulverulenta*, a greenhouse species of this interesting family, said to be a native of South California, from which country it was introduced by M. Louis de Smet, who first exhibited it under the name of *E. farinosa*. It is easily increased from seed, and so will soon become plentiful. Plates 3 and 4 are devoted to *Amaranthus salicifolius*, a now well-known plant, introduced by Mr. J. G. Veitch, from the Philippine Islands. Plates 5 and 6 are devoted to a beautifully painted portrait of the fine hardy *Lilium*, named by M. Max Leichth. *L. tigrinum splendens*. The true variety is extremely scarce, at least nine out of every ten in cultivation are not true to the name they bear; when true, it is an exceedingly robust-growing and handsome variety. Plates 7 and 8 depict the queen of all the Maiden-hair ferns, the exquisite *Adiantum Farleyense*, so well known to most of our readers. Plate 9 is an admirably painted portrait of the lovely Californian bulb named *Brodiaea coccinea*, first shown at South Kensington by that well-known introducer of new plants, Mr. W. Thompson, of Ipswich. Plate 10 shows the two varieties of double autumn flowering *Colchicum*, the rosy purple and the pure white, depicted with admirable fidelity. The white variety of this beautiful hardy bulbous plant is far too little known, and too seldom seen in our gardens, the extreme robustness of its growth, and the profusion with which it produces its lovely pure white double blossoms in the middle of the month of September, each bulb producing from ten to twelve, making it a most valuable adornment for the autumn garden. Plate 11 is a portrait of a rather curious greenhouse shrub, named *Pinckneya pubens*, a native of Georgia, whence it was sent by its discoverer, the botanist Michaux, to the distinguished Carlsruhe horticulturist, M. Max Leichth. Its somewhat insignificant flowers are produced in bunches at the end of the shoots, and are garnished with curious large white bracts, resembling those of the well known *Mussaenda frondosa*, but the bracts of the *Pinckneya* are bordered with red lines. Plate 12 represents a hothouse shrub named *Psychotria cyanocæca*, a native of Nicaragua, which produces large clusters of purple berries. This plant was sent to Mr. Bull by the late Dr. Seemann, who says it is a plant much to be valued for the very exceptionally fine colour of its fruit. Plate 13 represents a pretty *Camellia*, of a bright rose colour, irregularly mottled with white, named *Carlotta Papudoff*. Plate 14 is a faithful representation of the beautiful and rare terrestrial orchid *Utricularia montana*, so beautifully exhibited at South Kensington on the 5th of June from Lord Londesborough's gardens. Plates 15, 16, 17, 18, 19, 20, are the Pears already mentioned. Plate 21 represents another new and good plant introduced by Mr. W. Thompson, of Ipswich, viz., *Delphinium nudicaule*; but the picture, we think, hardly does justice to this beautiful hardy border plant, as the centre of the blossoms seems to us to show too much yellow, and the fine clear scarlet of the outer petals is not shown with sufficient distinctness. Plates 22 and 23 represent the now well-known Queen of Primroses, *Primula*

japonica, and have the same fault (to our mind a serious one) of representing all the four or five whorls of flowers open and in perfection at one and the same time, whereas the fact is that before the fourth whorl near the top of the flower-stem even shows its colour the petals of the lowest and first opened whorl will have long ago dropped and have been replaced by green seed-pods. Thus more than two whorls are seldom or never seen in full beauty on the same plant at the same time, instead of four or five. Plate 24 represents Messrs. Veitch's fine *Primula cortusoides* *arvensis* *Lilacina*; this we think scarcely so faithful to nature as the plates in this work usually are, as, while it somewhat exaggerates the size of the truss and also the size of the individual flower-pips, it does not do justice to the beautifully clear lilac streaked with pure white which characterises the flowers of this exceedingly pretty primrose. It is as hardy as all the other varieties of *P. cortusoides* *arvensis*, and even stands out of doors during winter at Messrs. Veitch's establishment at Chelsea. Plates 25 and 26 represent, with admirable fidelity, one of Mr. John Waterer's fine hybrid seedling rhododendrons, named Joseph Whitworth, and exhibited by him some three years ago for the first time at his annual exhibition of these plants in the gardens of the Royal Botanic Society in Regent's Park. Plate 27 represents a set of those curious abortions known as double Gloxinias, or what should rather, in our opinion, be more correctly designated imperfect attempts at hose-in-hose Gloxinias. We do not think that any one who grew them one season would wish to see them taking up pots and room in their houses a second year.

W. G. G.

AIR AND RAIN.*

SELDOM, if ever, has a work issued from the press with higher claims to public gratitude than this, the object of the author, as stated in the preface, being to supply a systematic foundation for such an accurate knowledge of the composition and qualities of the atmosphere, under varying conditions of place, time, temperature, &c., as must inevitably lead to vital improvements in our sanitary arrangements. With this laudable end in view, he has here brought together a vast number of important facts, verified by repeated experiments and accurate analyses. "Chemistry," he remarks, "has not hitherto done enough in sanitary inquiries, and it ought to be able to relieve medical men of much of their heavy responsibility." The volume before us, however, seems likely to make up for any deficiency which has been felt on this head, and although not entirely written in what is termed "popular" language, it is sufficiently so to be read with interest by that portion of the community who are competent to feel the importance of the subject. After laying down the standard of pure air, viz.,—

	Volume per cent.
Oxygen	20.96
Nitrogen	79.00
Carbonic Acid	0.04,

he proceeds to give analyses of samples of air collected from a great number of places in which it is always more or less impure: dwelling-rooms, streets, theatres, mines, hospitals, &c., and dwells strongly on the necessity of attending to the quantity of deleterious matter, the presence of which may be expressed even by a minute fraction. The details of the experiments, particularly those made in the closed lead chamber, cannot fail to show how earnestly and conscientiously the author has followed up his purpose, and are of themselves guarantees for the accuracy of his conclusions. As might be expected, a very large proportion of the book is devoted to tables of analyses, but these constitute its most valuable part, and, to our Boards of Health, supply data which are simply beyond value, and of which we trust they will not be slow to avail themselves. The same plan has been pursued by Dr. Smith with respect to Rain, specimens of which were collected from many parts of the country and analysed with various results. Most people think that no water is purer than rain-water, but these analyses prove that in the neighbourhood of towns this is not so, and that the rain which falls there is always more or less charged with impurities in the shape of sulphuric, or hydrochloric, or nitric acid, albuminoid ammonia, and near chemical works and blast furnaces, with arsenic acid and many other extraneous matters. It is the presence of these acids in the air which is so fatal to vegetable life in cities, the smoke of our chimneys always containing more or less sulphuric and other acids, which in dry weather poison the leaves, and in wet weather are washed down to and poison the roots of many trees and plants. Dr. Smith has found that "when the air has so much acid that two to three grains are found in a gallon of the rain-water, or forty parts in a million, there is no hope for vegetation in a climate such as we have in the northern parts of the country. The acid is calculated as dry sulphuric,

* "Air and Rain." By Robert Angus Smith, Ph.D., F.R.S., F.C.S. London: Longmans, Green, & Co.

but to some extent the agent may be hydrochloric rendered free by the sulphuric acid decomposing the common salt" (p. 246). The tables of analyses in this part of the book are very interesting, the samples of rain from different towns showing marked peculiarities in their composition, all, however, being more or less impure, and teaching us that if we want pure rain-water we must go for it to the open country or to the seaside (where it is purest). The volume closes with an extract from the report of the Belgian Commission on the Effects of Acids on Vegetation, in which the facts are stated with Continental minuteness and precision, and the subject discussed with considerable ability. In reading it, one of the most pleasing reflections is that the question is not confined to ourselves, and that, as the savants of other countries are devoting themselves to it in conjunction with those of our own, we may reasonably look for the discovery of such remedial measures as the intelligence of the age is, in a manner, bound to supply.

A BOOK ON ANGLING.*

MR. FRANCIS's high reputation as a master of the "gentle art" is more than sustained by his book, which is the most complete work on the subject that has yet appeared, and, as might be expected, has already reached a third edition. Treating of every branch of angling in a clear, practical, and exhaustive manner, he has bestowed especial pains on the chapters on fly-fishing for trout and salmon, which occupy the greater part of the book, and embody the results of his great experience in language pleasant to read, and intelligible even to juvenile disciples of the craft. The fullest instructions are given for tying artificial flies (with illustrations) and the preparation of tackle of various kinds, together with a carefully selected list of the best flies both for trout and salmon, the coloured illustrations of salmon-flies claiming especial notice. In fine, nothing has been omitted to render the book, what it is, the best book on angling extant.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 84.)

GENERAL RULES FOR SOWING SEED.

MOISTURE, a degree of heat adapted to the kind of plant, and air, are the three conditions on which the germination of seeds depends.

MOISTURE.

This is the first requisite. When water penetrates into the inner part of the seed it swells the germ, causing the outer envelope of the seed to burst, and dissolving the supply of nutriment laid up in the inside of the seed, which is to support the young plant until its roots are somewhat developed.

HEAT.

Heat is the stimulating principle; but the degree which is necessary for germination differs according to the natural habitat of the plant. Seeds of plants from cold, or moderately cold, regions will germinate in a temperature of from 35° to 45° Fahr.; those from temperate, or moderately warm, latitudes in a heat of from 50° to 65°; and seeds of tropical plants in one of from 70° to 90°. There are, however, many exceptions to these rules, of which we shall mention a few. Some of our commonest annuals, as for instance common chickweed, will germinate at a lower temperature than 35°. There are, moreover, many seeds of plants of cold and temperate regions which, even when suitable moisture and heat are applied to them in spring, do not germinate so soon as if they had previously been exposed in a moist state to a degree of cold below freezing-point. This appears to have the effect of disintegrating the particles of nutritive matter in the cotyledons, and so hastening the germination of the young plants. Of this class are the seeds of maples, *Cratægus*, and many umbelliferous plants, especially those found on the higher Alps, or in very cold latitudes. The seeds of many of the latter when cultivated are often sown in snow, as are also those of Alpine Roses, and different species of *Aretia*, *Azalea*, and *Gentians*. The seeds of trees and perennials from temperate regions usually germinate with the greatest certainty in a temperature of from 45° to 55° Fahr., and a higher temperature than this, so far from hastening their germination, usually impedes it. It is different with most annuals, the seeds of which germinate more speedily in proportion to the height of the temperature, provided it does not exceed 90°. Young plants of these kinds,

* "A Book on Angling." By Francis Francis. Third Edition. London, Longmans, Green, & Co.

after germinating, should at once be placed in a lower temperature. We shall here give a few examples of some of the commoner plants as illustrations of what we have stated. The minimum temperature at which germination takes place is from 38° to 40° for lentils, clover, lucerne, wheat, barley, rye, mustard, radishes, and cress; 43° for carrots, broad beans, and spinach; 45° for summer-blooming plants; 48° for buckwheat and maize; 50° for beans, and 55° for pumpkins. The maximum temperature at which germination takes place is 112° for cress, pumpkins, and maize; 110° for beans; 104° for broad beans, wheat, and barley, and 100° for peas. In such annual plants the nearer the temperature approaches the maximum the sooner will the seeds germinate: for instance, maize germinates in thirty to thirty-five days, in a temperature of from 45° to 56°; in twenty to thirty days, 67° to 75°; in seven to eight days, 90° to 100°; barley in forty to forty-five days, in a temperature of from 35° to 45°; in twenty to twenty-five days, 55° to 60°; in ten to twelve days, 94° to 100°. For tropical seeds we have named a temperature of from 70° to 90°; but there are some seeds which require a still greater heat to cause them to germinate: for instance, the seeds of the gigantic water-rose of the Amazon river require a heat of from 95° to 105° before they will germinate.

AIR.

The third condition necessary for germination is the free access of air. All the changes which take place within the body of the seed can only occur under the influence of air, from which certain gases are absorbed and assimilated by the seed, and by which other matters are removed from it. Therefore, no method of sowing should ever be used in which the air is entirely excluded from the seed.

Moisture, heat, and air, then, are the three conditions on which germination depends. If any of these are wanting, the seeds will not grow. The absence of light is often mentioned as another condition, but this is not really the case. Seeds are usually covered with soil when sown. From this, the idea has here and there arisen that absence of light is indispensable to germination. But the covering of soil is only necessary to preserve an equable condition of moisture around the seeds. If some of the finest and smallest seeds, as, for instance, those of *Calceolarias*, *Ericas*, *Rhododendrons*, *Epacris*, &c., are sown on the surface of the soil, and an equable condition of moisture maintained by covering the pot with a pane of glass, the seeds will germinate in the full sunshine much better than if they had received a slight covering of soil. This is a plain proof that absence of light is not a necessary condition for the germination of seeds. Some might be, on the contrary, led to hold that some degree of light, however small, is necessary to germination, as it is well known that seeds which lie deep in the earth, and possess the other conditions of warmth and moisture, yet do not germinate; but this is more properly to be attributed to the absence of air, for it can be easily proved that seeds will germinate in perfect darkness. The writer has found by experiment, that the seeds of cress germinate in perfect darkness quite as speedily as in the full sunshine, other conditions being the same.—*Dr. Regel.*

(To be continued.)

Plant-Baskets in the House.—The hanging-basket is perfectly manageable indoors, though rarely seen there. Some baskets have a little tap and cock placed at the lower point, so that the drainage may be drawn off with ease and at pleasure. A perforated false bottom allows the water to fall through from the roots of the plants to the lower receptacle, whence it is drawn off. There is a race of plants that, planted in this kind of basket, would require little or no water in winter, and these the reader may see in perfection in the succulent house at Kew. *Hecktia*, *Aloe*, *Tillandsia*, are likely to furnish the best things in this way; but there are other allied families from which valuable subjects may be selected. For such baskets nothing could be better than the various trailing and drooping plants which thrive indoors or in dry greenhouses. Even some ferns would do well; we have seen a plant of *Nephrolepis exaltata* stand for four months on a hall table, consuming abundance of water, and throwing its graceful fronds about as freely as in a fernery; and there are various others which thrive well in a sitting-room, notably *Asplenium flagelliforme*.

PUBLIC GARDENS.

SEFTON PARK, LIVERPOOL.

TEN years ago, Liverpool, the second city in the kingdom, had but one public park (Prince's Park), which was of no great size and was situated at some distance from the central parts of the city. The public voice soon called for additional places of recreation, and the Corporation, in 1863, demanded of the Government the necessary authority of an Act of Parliament to enable them to carry out these views. After a considerable amount of carefully prepared estimates, &c., on the part of the chief engineer of the city (Mr. Newlands), a large extent of ground was purchased to give Liverpool three parks, namely, Newsham Park on the east, Stanley Park on the north, and, last and largest, Sefton Park on the south. The ground for the last-named was purchased from Lord Sefton and Mr. Livingstone, for the large sum of £275,863. The total area of Sefton Park, which has been named after the principal of its former owners, is 387 acres. It lies south-east of Prince's Park, Ullet Road, Aigburth Road, Mossley Hill, and Smith-down Road. A natural rivulet, named Oskesles Brook, ran from north to south and formed a valley, which has been carefully made the most of and embellished; and a picturesque ravine, running from east to west, supplied an excellent opportunity of varying the aspects of the broken ground by the formation of cascades and waterfalls. From the highest point, which is about one hundred feet above the level of the Mersey, a magnificent view sweeps over the broad estuary of the river and the adjacent country, bounded by the outlines of the Welsh mountains and the hills of Overton. The ground having been secured, the Corporation, in November 1866, opened an international competition for designs and estimates for the formation of the park, and offered two prizes, one of three hundred guineas, and the other of one hundred and ninety guineas. A large number of landscape-gardeners entered the lists, and out of the twenty-nine eligible competitors who had fulfilled the conditions of the programme, the judges, on the 1st of May 1867, decreed the first prize for designs to M. Ed. André, the chief landscape-gardener of Paris, and to Mr. Hornblower, architect, of Liverpool, who were partners in the contest. The second prize was won by Mr. Milner, landscape-gardener, of Sydenham.

M. Ed. André and Hornblower were entrusted with the execution of the works, with a commission of five per cent., and on the 6th of June 1867 their terms were accepted. The estimates, which were at first laid at £85,000, ultimately swelled to the sum of £100,000, in consequence of the purchase of more ground from Mr. Livingstone for £12,000. Certain badly-disposed persons (for the most part unsuccessful competitors) did not scruple to find fault with this increase in the estimates, without appearing to have considered that it arose solely from the addition which was made to the park by the purchase of fresh ground subsequently to the estimate which was made in the first instance. Afterwards, other works, sanctioned by the Improvement Committee of Liverpool, and occasioned by unforeseen difficulties in carrying out the original design, raised the total expenditure to a sum which will probably be about £140,000, but it is nevertheless true that the original estimates of M. Ed. André and Hornblower would never have been exceeded had it not been for these unforeseen complications.

Of the total area of the park (independent of a certain space reserved for building lots, which will be sold and recoup a great part of the outlay), about thirty acres are set apart as an exercising ground for the Lancashire Volunteers and the Militia; the ornamental waters occupy more than twelve acres; a large proportion is devoted to "cricket," eight or ten matches of which may be played at the same time, and the rest of the space is occupied by the lawns, plantations, turf slopes, roads, walks, and ornamental accessories of various kinds. Among the vast interior and exterior thoroughfares of the park, it was resolved upon to establish a second "Rotten-Row," on the model of the fashionable resort in Hyde Park, and, accordingly, the dainty dames and knights of Liverpool may now enjoy to the full the pleasures of equestrian excite-

ment from Ullet Road to Garston Entrance. The distance is a mile and a half, and as there is a similar route within the park on the same side, the ride may be extended to three miles.

The designers, not losing sight of the necessity of providing long promenades in the park, and to make them as varied as possible, have made walks in every direction in which a visitor may have an agreeable view. The carriage roads alone are more than ten miles in length, and are all macadamized with broken granite, levelled by the powerful steam-rollers of the Corporation, and covered with a layer of fine gravel, over which the steam-rollers have also passed, and this affords a perfectly even surface even for pedestrians. The walks are formed of stone, cinders, and a layer of yellow Jersey gravel, and they have been made so as to conduct the visitor to every point of view that presents any attraction; they are generally ten feet wide, while the carriage roads vary in width from thirty to seventy feet.

One of the chief characteristics of the park is the lake and the general arrangement of the ornamental waters, which occupy a large area. As we have previously stated, the ground is divided by two valleys. Where the larger valley entered the park from the adjacent fields, the great circular road formed a natural intersection. The designers took advantage of this to form a wide slope here, in the side of which has been constructed a picturesque grotto of considerable size, out of which issues the stream, whose capricious meanderings follow the windings of the valley, its course being continually changed by a series of rocky barriers, until it finally flows into the lake. The drainage of the park from all points falls into this stream, and is of itself almost sufficient to feed it.

The other valley, which is shorter, more confined, and also more winding in its course, lies between steep slopes studded with rocks. At one end there is a cascade of great size, and the entire bed of the stream is thickly set with blocks of stone, which, like those used in forming the great cascade and the grotto, consist of the natural stone of the district—the red sandstone of Liverpool. All these stone constructions are the work of M. Combaz, the eminent architect who has built the Cascade de Longchamps, at Paris, and has constructed similar works in the Bois de Boulogne, the Bois de Vincennes, and in the squares of Paris. The lake, which covers more than ten acres, is sufficiently large for sailing and rowing matches. Its bed has been excavated out of the rock, and its margin has been laid out so as to present a varied succession of graceful windings and bold projections.

The plantations in general, and those on the margin of the lake in particular, have been the object of M. André's most careful attention. In one part of the park he has planted forest trees in broad groups and long shady rows, affording a solid screen to shelter the choice trees inside, which could not withstand the violent winds so prevalent at Liverpool. Outside of the wooded part on the south side, consisting of groups of more than ten acres together, through which here and there some vistas have been cut, the rest of the groups have been disposed, as may be seen in the annexed plan, so as to enclose the chief points of view and to form a series of plans which compose the scenes of the entire landscape. It may be observed that the park had to be entirely planted, as previously it did not contain a single group of trees, and that the soil was purely that of arable land. If, on the one hand, this absence of trees left the designer full scope for the exercise of his taste in forming the plantations, on the other hand, it was necessary to cover this bareness by planting strong trees, which were removed by the thousand to Sefton Park from Lord Sefton's property at Toxteth.

An idea may be formed of the extent of the plantations when it is stated that more than 200,000 trees have been employed. The expectations of M. André, as to the result of these groups in forming a shelter, have been already realized, and the success of the plan has exceeded all hope. In fact, on the day of the inauguration of the park by Prince Arthur (the 20th of last May), we saw the trees and shrubs, on the effect of which we had not reckoned for ten years to come, in a most satisfactory condition, and in two or three years more the park will be well furnished, its thirty-two acres of groups having been then only five or six years planted. The expenses

for the sewers, the drainage, the roads, and the addition of clay to certain parts where the soil was too sandy, have been very heavy, but the success of the plantations has been remarkable, the roads are unquestionably good and solid, and the drainage of the entire park is perfect. It was necessary, not only to carry out the plantations and all the requisite ground works, but also to enclose the park. Three patterns of railings, supported on a base-work of stone, were adopted, the plainest forming the boundary of the building-lots on the outside of the circular road, while the others enclose the park on the inside, and contain the necessary number of gates. The gate-houses for the park-keepers, and certain ornamental buildings have not yet been erected, and their construction must be a gradual work, lest the good people of Liverpool should grumble at such heavy expenses coming so closely one upon another.

It has been determined to have a botanic garden in the park, and this will supersede the old botanic garden of Liverpool, which the smoke of the town and the exhaustion of the soil have hindered from prospering. Up to the present it has not been commenced, but there is every reason to hope that the project will be carried out as designed.

The foregoing is a rapid sketch of the great new park at Liverpool. We do not know what judgment posterity will pass on those who have designed it, or on its value as showing what may be effected in the way of landscape gardening, but we do know that it was an immense undertaking, entailing long and careful study and laborious operations, and we believe it to be well worthy of the attention of all who take an interest in the art of gardening.

THE PLANT NURSERY OF PARIS.

THE projected removal of this is strongly denounced by M. Carrière. The ostensible grounds which have been advanced for pulling down this old and well-known establishment (the nursery and propagating-house of the plants which are employed in embellishing the squares of Paris), namely, to afford space for the continuation of the Rue Spontini and the Boulevard Flandrin, he considers to be a mere pretext, veiling the designs of private speculators, who are eager to secure the ground for building purposes. He goes even farther than this, and speaks of it as a well-known fact that these gentlemen actually have the plan of the prospective building-lots drawn out and ready. No doubt the value of the ground as a site for dwelling-houses would be vastly increased, but the advantages which would accrue to the city from the continuation of the street and the boulevard, would be more than counterbalanced by the removal of the Fleuriste to such a distance as is proposed, viz., "The Parc des Princes, between Boulogne and the Point du Jour." The transport of the plants to the city from this distant point would involve permanent labour, trouble, expense, and loss of time, while the plants could not be expected to arrive in the best condition after their long journey. In addition to this, the re-erection of the edifice itself would entail no inconsiderable outlay, as much of the iron-work, which, as it stands at present, would hold good for years to come, would have to be replaced by new material in the new building, so that, on the whole, the loss, even in a pecuniary point of view, is a matter not to be overlooked. The protest of M. Carrière appears to us to be both reasonable and well-founded, and we believe that the people of Paris will have good cause to lament if the proposed relegation of the Fleuriste be carried into effect.

THE FLORIST.

THERE is my friend the weaver; strong desires
Reign in his breast; 'tis beauty he admires.

* * * * *

For him is blooming in its rich array,
The glorious flower which bore the palm away.
In vain a rival tried his utmost art,
His was the prize, and joy o'erflowed his heart.
'This, this is beauty! cast, I pray, your eyes
On this my glory! see the grace—the size
Was ever stem so tall, so stont, so strong,
Exact in breadth, in just proportion long?
These brilliant hues are all distinct and clean,
No kindred taint, no blending streaks between;
This is no shaded, run-off, pin-eyed thing,
A king of flowers, a flower for England's king!'

—Crabbe.

THE ARBORETUM.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

CELS'S LARGE-FRUITED THORN (*CRATEGUS CELSIANA*).

THIS very distinct thorn forms a robust, free-growing tree, from fifteen to twenty feet high, with rather a spreading head, stout branches, and downy spineless shoots, and when covered with its fine compact heads of large flowers in June, and its large oval yellow fruit in the autumn, it makes a fine display. It is a native of Sicily, where it grows on mountains, and was first introduced in 1816. It is one of the latest of all thorns in leafing and fruiting. The leaves are large, ovate-acute, deeply incised, and taper much to the foot-stalk; when fully matured, they are of a deep glossy green above, downy beneath, and on rather long stalks; the lobes are oblong-acute, regularly and acutely toothed on the outer edge and near the apex, and increase in size from the point to the base of the leaf. The stipules are small and acute, but frequently wanting. The flowers are large, pure white, very fragrant, and produced in close heads in June. The fruit is large, oval, downy, of a yellow colour, and ripens

Leaf of Cels's large-fruited Thorn; natural size, $2\frac{1}{2}$ inches broad and $3\frac{1}{2}$ inches long, including the footstalk.

at the end of August, but it hangs on the tree until the leaves fall off. This kind of thorn must not be confounded with the *Crataegus oxyacantha celsiana*, which is a mere variety of the common hawthorn. Its synonyms are *Crataegus incisa* and *Leeana*, and *Mespilus celsiana* and *laciniata*.

THE SHRUBBY REST-HARROW (*ONONIS FRUTICOSA*).

AN ornamental small bushy shrub, which grows from two to three feet high and flowers abundantly in May and June. It is well suited for planting on rockwork, or in the front of shrubberies, as it thrives well in any open situation and soil that is tolerably dry. It is a native of the south of France, where it grows in sunny places, especially on the Alps of Dauphny and Provence. It is readily increased by means of seeds; it was first introduced in 1680. The leaves are alternate, trifoliate, and deciduous, with the leaflets lanceolate, serrated, and without footstalks. The stipules are joined in one, forming a sheath, with four long bristly points, which in the uppermost part of the plant occupy the place of leaves. The flowers are pea-shaped, tolerably large, and of a purplish-red colour. The pedicels are three-flowered, disposed in a raceme rising from the axil of the leaves. The pods are puffed up, few-seeded, and brown when ripe in September.

VARIETIES OF THE COMMON LAUREL.

LET us advert in the first place to the forms most nearly related to the common Cherry Laurel (*Cerasus Laurocerasus*)—itself too well known to need more than a passing reference. Of these the most prominent is the Versailles Laurel (*latifolia*), a very large-leaved kind, differing only in size from the common sort. When first introduced at the meetings of the Floral Committee a year or two since, a very proper doubt was entertained as to whether or not this extra size might be merely the result of special culture, but we have since seen it at the Tunbridge Wells Nurseries growing freely by the side of the common laurel, and maintaining a decided difference, both as to robustness of habit and boldness of foliage. Whether it is more or less tender than the type, which, we all know to our regret, sometimes gets severely touched by frost, we are not aware. Another variety, also closely related to the common laurel, is the round-leaved laurel (*rotundifolia*), which has been exhibited by Mr. W. Paul, and which we have noticed growing in his nursery at Loughton, in a situation where its hardiness was thoroughly tested. The habit of this sort is very dense; the leaves, though not exactly round, are particularly broad and short, and are serrated at the edge, and the whole plant appears to us to have an aspect recalling that of a bay laurel rather than a cherry laurel. We look upon this as one of the best of the forms belonging to the same race as the common laurel, while a narrow-leaved form, occasionally seen, is one of the worst from an ornamental point of view. Of a distinct and hardier type is what is known as the Colchican Laurel (*colchica*). One of its peculiarities is its remarkably spreading habit of growth, without much tendency to get upwards, a quality which seems to adapt it specially for planting as undergrowth or cover. Another of its peculiarities is the pale hne of the back of the leaf, which somewhat detracts from its beauty as an evergreen. The leaves are rather lengthened out, conspicuously pointed and glossy, and have a sort of refined character, which no doubt would command the approval of most persons of taste in these matters. It is, undoubtedly, a better evergreen than the common laurel. The Caucasian Laurel (*caucasica*) is again of another distinct type, and, so far as we have been able to observe, is the most valuable of all the Cherry Laurels we have in cultivation. It has a bolder and more vigorous style of growth than the common laurel, is naturally much more inclined to assume an erect habit of growth than *colchica*, and is, at the same time, dense and well furnished, thickly clothed with fine, broad, dark green glossy foliage. What is, however, of still more importance, in regard to an estimate of its merits, is the fact that it is hardier than any of the other varieties. The Cherry Laurel is so often and so much in request as a shrubby plant, that we trust our readers will find these brief memoranda of the peculiarities of the different kinds useful to them in making their selections, now that the planting season has again come round.—*Gardeners' Chronicle*.

The Weeping Willow.—This, says the *New York Tablet*, has a romantic story. The first scion was sent from Smyrna in a box of figs to Alexander Pope. General Clinton brought a shoot from Pope's tree to America, in the time of the Revolution, which, passing into the hands of John Parke Curtis, was planted on his estate in Virginia, thus becoming the progenitor of the weeping willow in America.

The Parliament Oak.—"Edward I. held a great council under the shade of an immense oak, the well-guarded trunk of which is yet standing, at the corner of Clipston Park, on the side of the road between Mansfield and Edwinstowe, and is famous through all the country-side as 'Parliament Oak.' This event is dated by historians in 1290, as consequent on some information the king received, while hunting in the forest, of a revolt of the newly-conquered Welsh, against whom he immediately proceeded."—*Spencer T. Hall's "Forester's Offering."*

A Monster Tree.—In Major Bell's "Other Countries" (Chapman and Hall) we read of "the greatest tree in the world" growing near Hobart Town. Yet were no means of arriving at its precise dimensions. But, pacing it round its base, Major Bell measured thirty-one yards, and "bleached and branchless till near the top, its huge stem disengaging itself from its base of roots, rises in a girth of eighty feet, from roots that overtopped the boy who guided me, and perhaps were five feet in height." He has some reason for surmising that this Tasmanian monster may hold its own even with the world-renowned giants of the Californian forests.

Viburnum plicatum tomentosum.—This variety, which, according to M. Carrière, in other respects, is almost precisely similar to *V. plicatum*, differs from it in its flowers and comparative hardiness. In the last respect it falls far short of *V. plicatum*, as it perishes under a few degrees of frost, while *V. plicatum* is not sensibly affected by the most intense cold. The flowers are very like those of *V. Opulus*; those at the circumference of the umbel are simple, five or six in number, and form a very elegant collar or crown encircling the central flowers, which are very small. In a cool house it blooms about the 20th of April, and in the open air early in May.

OUR SQUARES.

AMONG other good things, says the *Telegraph*, which the Arab proverb enjoins us to do that we may make sure of entrance into Paradise, is the planting of a tree. Leigh Hunt, than whom no truer lover or more refined appreciator of nature ever lived, used to boast that whenever his domiciliary circumstances permitted, he strictly carried out the behests of the Eastern sage. But if the planter of a lime or a plane tree is deserving of hearty praise, what, it may be asked, should be the meed of eulogy bestowed on him who endows his contemporaries with a new garden? That those who are blest by fortune with adequate means, should in such a manner earn the gratitude of their fellow creatures, is, from every point of view, beautifully appropriate. The best and the wisest men that have ever lived have been the greatest lovers of gardens. One of Bacon's most eloquent essays is on gardening; and, as Evelyn did after him, he wrote learnedly and enthusiastically on arboriculture. The germs of the Renaissance of Italian art blossomed in the gardens of Lorenzo de Medici; and two of the noblest of English poets, Milton and Spenser, have in their writings shown themselves as proficient in horticultural lore as Virgil approved himself in husbandry. Practical country gentlemen, and even botanists, may yet learn something from the deathless word-picture of the Wandering Wood; and that the grandest and subtlest human minds should thus take delight in sylvan scenes and flowery pleasantries is meet when we remember that it was in a garden, when time was young and sin was not, that the Almighty bade his creatures be happy.

When a foreigner comes among us and we strive to guide his footsteps through the mazes of this enormous capital, he may at the first blush imagine that of all cities in Europe, London is one of the most richly gifted with gardens. He may be justified, indeed, in such an assumption when he listens to our own pardonably complacent encomiums on St. James's and the Green, on Hyde and the Regent's, on Battersea and Victoria parks, and on the exquisitely beautiful Kensington Gardens—all wonderfully developed and improved, and some of them created, within the last twenty years. But our parks, he may think, are not our only pleasure grounds; nor even when he has been taken to Hampstead Heath and to Primrose Hill, and to the coquettish little *bosquets* which are springing up on the Thames Embankment, may he consider our catalogue of places of public recreation to be exhausted. Peeping through a gilt and armoured *grille* in the Kensington high road, he may have seen the noble avenue of antique trees which leads to Holland House. Again, in pleased wonder may he lift his hands as a river steamer bears him past the velvet meads and spangled pastures at the rear of those old Inns of Court where once the Knights of the Temple dwelt, "ere they decayed through pride." Once more, crossing Berkeley Square, may he find himself in a very grove, with the towering elms and oaks of the square itself on one side, and the venerable gardens of Chesterfield and Lansdowne houses on the other. Grosvenor, Russell, Belgrave, and a score more West End squares will alike please his eye; and especially will his curiosity be gratified by the sight of the enclosure of Lincoln's Inn Fields, an earthly paradise of umbrageous luxuriance, in which all Mr. Morris's story-tellers might tell their tales till London falls to pieces and the New Zealander comes to sketch it. Of what, then, our critic from abroad may ask us, have we to complain? What is Paris, with its Tuileries and Luxembourg gardens, its Park Monceaux and its Square Montholon? What is Florence, with its Boboli and its Cascine? What are Vienna, with its Volksgarten and its Prater, and Rome, with its Pincio and Borghesi gardens, in comparison with London? And have we not the Royal Horticultural, the Botanic, and the Zoological gardens? Yes, we are fain to plead guilty to all these pleasant indictments; yet are we bound sadly to confess that in this city of four millions of inhabitants we have not half enough gardens for the gratuitous and unrestricted enjoyment of the people. For admission to some of our sylvan retreats a money payment is required; the public are only admitted by favour to the Templars' lawns; and the squares, being strictly private property, the privilege of wandering in their grassy and shady enclosures is reserved for the inhabitants of the surrounding houses and others possessing the power of the "key." In front of Carlton House Terrace, again, there are some very pretty gardens, on which the members of the Athenæum, the Travellers', and the Reform clubs may only look from their windows. The barring out of the public from Lincoln's Inn Fields seems a still harsher arrangement. Benchers' orders, it is to be presumed, admit a favoured few to the leafy thickets of one of the most antique and picturesque expanses in the metropolis; yet it is a sad sight to see, on broiling summer afternoons, tired children and weary nursemaids, with perambulators, looking wistfully through the railings of the "Fields," and contemplating the far-off Eden from which they are banished. Who will give a new and an eleemosynary garden in which the studious may saunter and children may play? The appeal comes from the inmost depths of the popular heart, and

it is gratifying to find that to such a request one most generous response has just been made. The Marquis of Westminster has determined (see p. 88) to try the experiment of providing an open garden for the use of the public.

As regards the advisability of removing or retaining railings, opinions may differ. It should, however, be enough to know that the gates will be thrown open from sunrise to dusk, and that the poorest portion of the community will have free right of entry into the new pleasaunce. No praise can be too warm in acknowledgment of this generosity; the step is as wise as it is munificent. Lord Westminster has struck a keynote to which harmonious reply must speedily follow. That the rights of property should be scrupulously respected is, in this country of reverence for law, a necessity and it is equally imperative that there should be no wanton violation of the privacy and seclusion for which the householders in a London square virtually pay when they disburse their quarter's rent. It would be impossible, under present circumstances, to throw open all the metropolitan squares to the public at large; still there are many which are under the entire control of noble proprietors, and there are others which have long since lost the aristocratic stamp they once possessed, and which, being now situated in populous and indigent neighbourhoods, might be most beneficially utilised as places of popular recreation. What body of householders, for example, would take any harm if Soho, Red Lion, and Golden squares, and, in particular, if Lincoln's Inn Fields, were thrown open as playgrounds for the people? The example set by the Marquis of Westminster will, we are convinced, bear good and speedy fruit. The landlords of the virtually unused spaces have everything to gain and nothing to lose by adopting a policy of liberality; while to the public the advantage derived from the concession would be of a double nature. Our parks are numerous, but they are in most cases too far removed from densely crowded neighbourhoods. That children or their elders would misconduct themselves in gardens set apart for their use is a contingency not to be entertained by rational minds. Every additional garden thrown open is a lesson and incentive to the poor to comport themselves with propriety. Already they do so in the few gardens they possess, and their decorous bearing would, we are persuaded, be increased in a proportionate degree were the parks, the gardens, and the playgrounds of London multiplied a hundredfold.

PARK BATHS.

AGAIN the "heated term" has set in, and once more is seen the disgraceful state of the bathing arrangements in Hyde and other parks. There is no city in the world in which a series of convenient open-air swimming baths could be so economically made as in London. Abundance of wide-spreading park and garden ground belonging to the public is at hand in which capital sites occur. Our parks are not, like those of Paris, without the city, but for the most part quite surrounded by it, so that swimming places in them would be most convenient for the inhabitants of the surrounding districts. Consider, for example, what a boon one or more small swimming lakes in Regent's Park would prove to the many densely-inhabited districts around it. The land in the possession of the public, the excavation and proper shielding of such by belts of varied plantation would be quite easy and inexpensive. Something like a model for an open-air swimming bath already exists in Victoria Park. Such baths once formed would entail little or no expense for keeping more than would be bestowed on the same piece of ground if kept as a park or garden. Shrouded by shrubbery, they could be used for fourteen hours of the summer day, while, if their disposition were entrusted to a good landscape gardener, they and their surroundings could be made charming embellishments of our parks, now in many parts naked and unattractive. It is needless to point out how beneficial such a series of baths would prove to the population of London, by placing within reach of all the means of practising in the open air, and in the pleasantest manner, the doubly useful exercise of swimming. They would be worth constructing merely for the sake of getting rid of the wonderfully scandalous spectacles which may now be seen every morning and evening on the banks of the Serpentine. Here the army of the great unwashed is so densely packed, that none but the roughest and those with the least-developed sensibilities could enter the water; and, indeed, it is not quite pleasant to go near the margin when the crowd is away, for the authorities make no sanitary provision whatever for the great multitude, and the place is filthy to a degree not pleasant to see illustrated within a few hundred feet of the most fashionable lounge and drive in Europe, and in our most popular and expensively embellished public garden.—*Field*.— [The suggestion alluded to last week, as to bathing places in the centre of islands in such a piece of water as the Serpentine, is a capital one which we hope to see acted upon. More convenient, if not so picturesque, would be little bays opening from the main sheet of water and surrounded by dense plantations.—ED. GARDEN.]

WE hear that a farmer has refused to buy a sewing-machine on the ground that "he sowed his wheat out of a bucket."

GARDEN DESTROYERS.

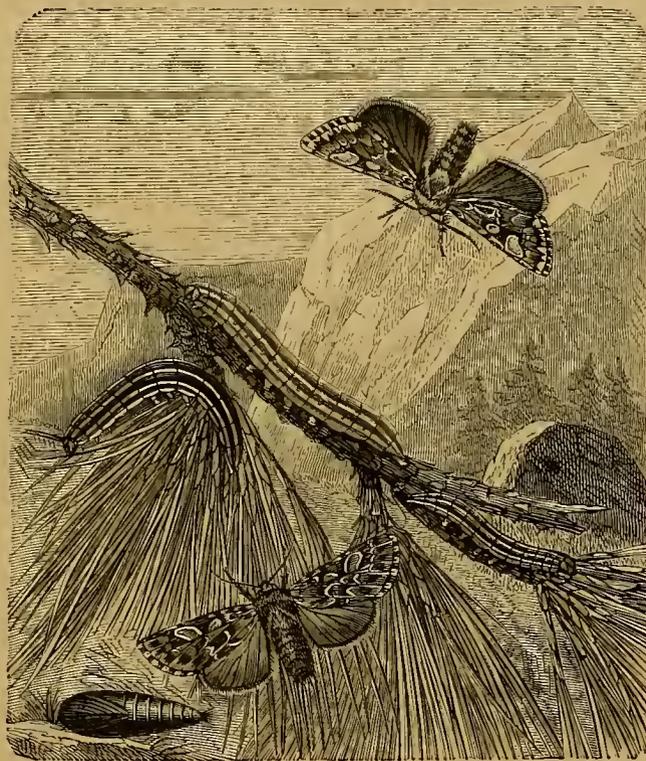

NOCTUA (TRACHEA) PINIPERDA.

ANOTHER moth which, although not so formidable as some of its congeners, still, from time to time, causes considerable injury to pine trees, is the *Noctua piniperda* of old authors. The accompanying woodcut shows the caterpillar in its different stages—the chrysalis, and the male and female moth, all of the size of nature; the upper figure, with serrated antennæ, being the male, and the lower, with filiform antennæ, the female. The caterpillar is grass-green, with white stripes and an orange-yellow one along the line of spiracles, the lateral stripe is margined with a delicate black streak, and small black dots are scattered over the body; the underside is paler than the upper, and the head is pale brown.

The chrysalis is reddish brown; that of the male is smaller and harder than the female, and has a small elevation on its back. The moth is variegated with brown, grey, yellow, orange, and red; the outer margin of the upper wing is pale yellow, with eight red spots running along it; the darker parts in the figure are reddish-brown, the paler yellow or orange; the thorax is variegated with red, orange, and light grey or white; the abdomen is brown, turning reddish towards the tip; the effect of the whole being a mixture of colour wonderfully like the bark of the fir tree, on which it rests. The caterpillar feeds on the leaves of the pine tree, and is said by Kollar to prefer trees of from fifty to a hundred years old, and only to attack young trees and young shoots when it cannot get older ones.

The moth appears in spring, but the date of its appearance varies according to the weather. If it has been very warm and genial it may come out in April, or even in March; if the season has been backward it may not appear until May or June. It sits by day on the trunk of the tree, generally pretty high up, and from its similarity to the bark in colour is not readily observed. The female lays from forty to sixty eggs, of a pale green colour, singly on the points of the foliage. After the lapse of about fourteen days, the young caterpillars are hatched, and they begin eating at the point of the leaf and work backwards to its base. They live singly, and continue feeding for six or seven weeks (changing their skins several times), and about the middle or end of July or beginning of August, they pass into the chrysalis state in the earth or moss at the roots of the trees. They do not readily crawl along the trunk, but let themselves down the trees by a thread. They remain in the pupa stage all the winter, thus producing only one brood in the year.

No special remedies for, or protection against, this species have been proposed. The same that are used against other moths apply also to it; but a considerable number of ichneumons seem to be specially appointed to keep it within bounds. Eleven or twelve species are mentioned by Ratzeburg as particularly fatal to it. It is fortunate that the insect, in all its stages, is very susceptible to changes of weather, which often destroys many.

Noctua piniperda.

It is found both in England and Scotland in most pine woods, but we have not met with any notice of its occurrence in Ireland. A. M.

THE NEW VINE PEST.

WITHIN the last few years a new plague has, in the south of France, excited even more alarm than the oidium itself, from its insidious invasion and complete destruction of many of the most valuable vineyards. The germs of the potato-fungus, of the péhrine, of the oidium, are all invisible and inappreciable by any of our instruments; the history of their diffusion and early development, and even their very existence, can only be judged of from their results and other circumstantial evidence; whilst the *Phylloxera vastatrix* can be watched in every stage of its varied existence, from the first deposit of the fertilised eggs, through its several agamic generations, to the latest winged form. The researches, accordingly, which have been already applied to it have not been altogether barren of results, (throwing some light even generally upon the origin and dispersion of these pests. Considerable sums of money, either from the French Government or from private subscriptions, have been applied to the purpose, and the investigation has been chiefly carried on by Dr. J. E. Planchon, of Montpellier, assisted by M. J. Lichtenstein, a relative, I believe, of the late distinguished Prussian zoologist. These gentlemen, since the first discovery of the disease in France in 1868, have devoted much of their time to it. They have compared their observations with those of others who, in other countries, have studied the insect, especially M. Laliman, of Bordeaux, Mr. Riley, of Missouri, and with those of Professor Westwood in our own country; and they have now, in a pamphlet which, by some inversion of dates not uncommon abroad, is supposed to form part of the proceedings of the session of the French scientific congress at Montpellier in 1868, given a *résumé* of nearly five hundred memoirs, communications, or journal articles which have been published on the subject up to the close of last year (1871).

The main facts given as having been hitherto elicited as proved or probable may be shortly resumed as follows:—

The *Phylloxera*, like other aphides, goes through a number of apterous generations of a single sex, but multiplying with enormous rapidity; one or two individuals will lay as many as five hundred eggs, fertilised without previous copulation. It also gives birth occasionally to a winged generation of both sexes, the females of which lay only two or three eggs each. The apterous *Phylloxera* is also dimorphous, a smooth-bodied form living in little galls formed on the leaves of the vine, where it is comparatively harmless; and a tuberculate form living in the nodules it produces on the root fibres, causing first the smaller and then the main roots to rot, weakening, in the first instance, and finally killing the whole vine. Each form has its winged generation. The insect is evidently of North American origin, although the precise history of its transmission to this country has not been ascertained. It was first described by Asa Fitch in the *Transactions of the New York State Agricultural Society* for 1854; but living there chiefly on the leaves of the native vines, it had not attracted any peculiar attention. More recently, however, Mr. Riley has found reason to attribute to the ravages of the subterranean form the ill success of the various attempts made to establish in America the European grape-vine. In England, where the introduction of the insect from America may be readily conceived, Professor Westwood's attention was first called to it in 1863, and again from various quarters in 1867 and 1868. With us it does

not appear to have spread much, and has therefore not called for any further observation, the damp soil, the mode of treatment, or other external circumstances, proving unfavourable to the development of the underground form. But having by some means reached and established itself in the dry, naturally-drained vineyards of the south of France, its general character underwent a change; natural selection at once gave an enormous preponderance to the underground over the epiphyllous form. It was first discovered there in July 1868, and by the close of that year its ravages caused a panic among the vine-growers in many parts of Lower Languedoc and Provence, similar to that which we may remember in this country on the rapid spread of the potato disease in the autumn of 1845. It was immediately made the subject of scientific investigation, which has ever since been steadily pursued. As one result Dr. Planchon inclines to believe that the oidium and the potato disease, like the Phylloxera, and, in former days, the American blight of our apple trees, had all been imported from America. It would seem that all these parasites, whether insects or fungi, capable of enormously rapid and extensive propagation, remain unnoticed so long as they are kept in check by the mutual relations of their constitution, habits, food, and other circumstances in which they are placed; but that the moment that a change, often very slight, in one or other of these conditions destroys the balance, they may at once and suddenly gain the upper hand, so as to be classed in the popular mind amongst those varied phenomena collectively designed as blights. That such a change is often the consequence of the transportation of the insect from one country to another may be regarded as more probable if Riley is correct in his belief that in America, as in Europe, introduced insects, when once established, are more noxious than indigenous ones. In the case of the Phylloxera some clue to the nature of the influencing alteration may be derived from the success attending one of the remedies applied, the inundation and continued submersion of the diseased vineyards during the winter months. The comparative dryness of the soil in the new over that of the original station of the insect has been the change which natural selection seems to have seized upon to effect the extraordinary development of the underground form, aided, perhaps, by some slight attendant change in its constitution. Prolonged, or even temporary inundation, is not, however, practicable in the majority of the South of France vineyards, nor, indeed, in any of those producing the best wines. Amongst other remedies, soot (the soot of wood-smoke I presume) promises to be one of the most efficacious applications.—*From Mr. Benthams's Address at the Linnæan Society.*

MARKET GARDENS ROUND LONDON.

BY OUR SPECIAL REPORTER.

MR. GEORGE STEEL'S, PARSON'S GREEN, FULHAM.

THE immense importance of the London market gardens, and the usually high culture maintained in them, are known to many; but few have any opportunity of observing for themselves the details of the management pursued in them. One of the most exemplary of these establishments is that of Mr. George Steel, of Fulham, whose system of cropping and vegetable culture is of the most satisfactory character. The Fulham fields have a world-wide reputation for vegetable production, and a visit to them just now could not possibly be unprofitable, or without interest even to those not directly concerned in market gardening; for growers for market do not, like the great majority of private cultivators, grow everything they think edible. On the contrary, they only grow such things as suit their particular description of land best, and which return the greatest amount of profit. In some districts, Peas, Beans, and Potatoes form the main crops, but these are often many miles distant from London, where land is comparatively cheap, and where the growers can better afford to raise them than those about London, where, sometimes, the Pea crop itself scarcely re-pays its expenses. The wholesale vegetable markets are held early in the mornings, and the same waggons which convey produce to town over-night, take back stable dung in the morning, thus accumulating great masses of manure, all of which is used, in due time, for the land. Nor do market gardeners spare it, for on a liberal supply of this great essential do they depend for good crops.

ASPARAGUS.

This may be taken as the most important of market-garden vegetables; it is now left to itself, and is growing away quite strongly. It is planted in single lines about seven feet apart,

and when in double lines placed about two feet or so apart, a space of eight feet is left between these and the next two rows. The French are partial to blanched Asparagus; they say that in cooking, English people spoil the "grass," and that they affirm green shoots are best. The English certainly often give the preference to unblanched produce. Green Asparagus will not, however, sell even in the English market, consequently market-gardeners, in order to meet the demand, grow it in the way that suits the purchaser best. About the end of February or first of March, the soil in the spaces between the lines or rows is thrown right and left on the rows to the depth of several inches, thus forming high ridges with deep trenches between them. By the middle of April, if the season is warm, the young shoots begin to make their appearance. Then, as soon as the weather permits, a line of French Beans is sown along the middle of the ridges having only one line of Asparagus; but in the larger ones, containing two rows, three lines of French Beans are sown; these are now producing a crop. About the middle of June cutting of Asparagus is entirely discontinued, and the plants are allowed to grow at freedom. Just now, however, three lines of Coleworts are being planted in the trenches; the plants being large when inserted, are set about eighteen inches apart.

CABBAGE.

The Fulham or Enfield Market is the kind usually grown in market gardens. Sowings are made at various seasons throughout the spring, summer, and early autumn, not only for supplying hearted Cabbages, but also for Coleworts, which are young Cabbages before they begin to heart. Main crops are planted in early spring from twelve to fifteen inches apart each way; and as they begin to meet one another in the rows, every alternate row is removed for Coleworts, also every alternate plant in the row; the others are left to form hearts. During the cutting season, some of the finest Cabbages have pegs stuck in beside them to mark them. The heads of these are sold, but the stumps are retained for seed. In summer, Cabbages are only used as an intermediate crop, *i. e.*, they are planted between Moss Roses, beds of Asparagus, or in other places where other crops would not be likely to thrive. Seed for this purpose is sown early in summer in any corner that is to spare, and likewise between lines of spring-transplanted fruit-tree stocks for grafting on. For planting, good-sized plants are preferred to small ones, as being more likely to withstand warm summer weather. Advantage, however, is taken of showery weather for planting, if practicable. A line is now being planted along the centre of the space left between the Celery rows, in which the plants stand eighteen inches apart.

CAULIFLOWERS.

These form one of the principal spring crops. The plants are raised in frames in autumn, just protected from snow, hail, frost, &c., throughout the winter, and are planted out in February. They are not, however, kept altogether free from frost, but the less they get of it the better. When planted out eight or nine are placed under a handlight, which, if necessary, is covered over with litter during severe weather. As the plants advance, a few are lifted out, and either placed under other handlights, or are planted in lines three feet apart. Three or four is the quantity usually left under each light, and to them a little earth is drawn, thus forming as it were, a little basin, which is suitable for the retention of manure water, if time can be spared for its administration. Throughout the day, as the spring advances, the lights are either entirely removed or tilted up a little, and no sooner can the plants do entirely without protection than they are removed from them, and are next used for Vegetable Marrows. The second main crop is planted out in lines two and a half feet apart, and the space between is made up with Lettuces, which are ready for market some time before the Cauliflowers. This crop forms a fine succession to the other, and is succeeded by other later plantings, which are either put in in open spaces, and made up with other crops between, or they themselves are planted as intermediate crops between Cabbages. By the end of June all the Cauliflowers are removed and sold, so no time is lost. The main point of success, however, depends upon a free use of the hoe, and this the market gardener never neglects. In private gardens hoes are mostly employed to keep down weeds, but in market

gardens they are not only used for that purpose, but for pulverizing the soil, a practice which rapidly promotes the healthy development of the plants.

CELERY.

In the Fulham fields Celery does remarkably well. The plants are raised in frames having a little bottom heat, and are gradually hardened off until, before they are finally removed from the frames, the sashes are entirely removed from them. After being well exposed in the frames, about the middle of May they are dibbled out in the open ground in lines six inches apart and three inches from plant to plant, and between every nine lines thus planted an alley of eighteen inches is left; or they are planted out in lines nine inches apart, four inches asunder, and no alley left. They are thus allowed to remain until the end of June, when a good plantation is made, and the main crop is just now (last fortnight of July) being put in. All empty ground is now dug over and marked off into five feet spaces by a drill or mark being made across the ground. This drill for the earlier crops is hollowed out a few inches, thus forming four-foot beds and one-foot alleys. In these alleys the Celery is planted about eight or nine inches apart. For the later main crop, the alley is not taken out quite so deep; it just appears a little lower than the main surface. The space, or four-foot bed between the Celery lines is planted with a line of Cabbages along the centre about eighteen inches apart, and on both sides of this row, a row of Cos Lettuces is planted. In dry weather this crop is liberally supplied with water, but as yet this season, there has been no necessity for artificial watering; should water, however, become necessary good means are at hand for supplying it; trenches are dug out from the banks of the Thames across the fields, and owing to the land being level these trenches become filled on the rise of the tide, thus facilitating the watering of this and other crops. The earlier planted crops are supplied with a little soil by breaking down the sides of the ridges with a hoe. The Lettuces planted between them will, by the time the Celery requires a good earthing up, be ready for market, and are removed.

CARROTS.

These are treated like Onions, the Early Short Horn being the kind used. These are sown along with Lettuces, which germinate a good deal sooner than the Carrots; therefore as they come up, they are thinned, and as they become strong enough, are planted out, leaving the Carrots behind, which, while among the Lettuces get a little weak, but after removal of the Lettuces soon recover. Protection from frosts, cold, and heavy rains, &c., is given by means of sashes and coverings of litter. As soon as the Carrots are removed, a crop of French Beans is sown in the frames, from which the earliest supply is obtained.

CUCUMBERS.

Some idea of the quantity of Cucumbers grown in Mr. Steel's grounds may be obtained from the fact that he has 800 three-foot wide frames all occupied with them, and last week he sent to market about two hundred dozen good Cucumbers. They have the constant care of two men, who do little else besides attending to them. The young plants are raised in dung-beds and are potted off when ready, two being put in a six-inch pot. Two or three sowings are made according to the space that can be got ready for them, for it must be borne in mind that not only ground, but frames have to be got ready for them, and the latter in spring are filled with young Lettuces, Carrots, Onions, and Cauliflowers. In the end of March or first of April trenches are dug out four feet wide and two deep. These trenches are filled with fermenting manure, which is covered over with the soil that was taken out of the trench. The frames and sashes are then put on and the plants planted, there being two plants in each pot; these are allowed to remain together when planted, so that one potful is inserted in the centre of the bed under each light; one plant is trained towards the top and the other towards the bottom of the frame. For several weeks after being planted they are protected at night from cold by covering the sashes with litter, which is removed next morning. This has been discontinued for two months now, as the nights are warm enough for them to do without covering. Throughout the day they are allowed to have plenty of air, which is all taken off at night; as soon as

the men come in the morning they tilt up the sashes a little and if the heat of the day greatly increases the sashes are tilted up a little higher still, usually about three inches. Watering is performed in the morning, and is given abundantly to those requiring it, whilst those that are not dry have simply a sprinkling overhead. Shading is entirely dispensed with now, but in the event of strong sunshine it would again be resorted to. Cucumbers are gone over twice every week, for the purpose of removing all superfluous shoots and leaves. The shoots are pinched when quite young at the joint beyond the embryo fruit, and all branches getting naked and "blind" are cut out completely, so that nothing is retained but the healthy young fruit-bearing vines. Fruits that are coming crooked are placed in long tubular glasses, which prevent a deformed development.

FRENCH BEANS.

Of these great quantities are grown. The earliest crop is sown in frames that have just been relieved from young Cauliflowers and Lettuces, and protected for a time. After they come up they are gradually hardened off, by removing the sashes during fine weather, and only replacing them to protect the young plants from cold winds, frosts, hail, or heavy showers. Any vacancies that occur are made up from a reserve stock. This crop has been in good bearing now for several weeks. Another early crop was sown in lines in front of a south wall; these made such quick progress as almost to overtake the frame plants. The first main crop is sown about the middle of April, in lines three feet apart. This is not sown in open spaces, but lines are drawn for it between other crops, such as Cabbages, Cauliflowers, &c., and the seeds are sown so that by the time they get up the other vegetables on the ground may be removed. But this is not all, for no sooner is the old crop removed than the intervening spaces are planted with Cos Lettuces. Before the French Beans begin to require all the space the Lettuces have been tied up and removed for market. This first main crop is not all of one kind, but consists of alternate lines, one a dwarf, pale pink-flowered sort, and the other a much stronger-growing, free-blooming, and branched kind. This plantation consists of several acres, and so thickly are the plants now producing pods that a strong force of women is scarcely able to pick them as fast as they grow. Other plantations are coming on in succession, but they consist chiefly of dwarf-growing kinds, and the lines are further apart than the former, being about three and a half or four feet. This extra space is not, however, lost; on the contrary the late crops being only lately removed, the alleys are now being planted as time permits with two lines of strong Colewort plants. Before sending the Beans to market they are all washed to remove grit, and they are packed into common round vegetable baskets, which are piled one above another on large two-horse waggons, several of which are sent to market three times a week.

MUSHROOMS.

Mr. Steel has plantations of these, annually covering nearly an acre. They form a continuous series of ridges and furrows. At present the old Mushroom beds are covered with Tomatoes that were planted at their base. New beds will be formed towards the end of August or first of September, and each bed will occupy a breadth of seven feet, *i. e.*, a four-foot bed and three feet as an alley. Mushroom ridges are made of short stable dung, built up firmly to a height of nearly four feet, and about the same in diameter at the base. Over their whole surface two or three inches of loam are placed; they are then spawned and covered with a layer of rank stable litter. In November these beds are in good bearing, and go on producing good crops every week until May, after which their best season is past; yet some of them continue to bear freely for some time after that. When gathering the Mushrooms, the rank litter is carefully removed with a fork by one man, and after him come others with baskets into which the Mushrooms are put, and as soon as the ridge is cleared of all that are ready the litter is immediately replaced, for it is important not to allow them to become too much exposed at any one time. Mats, if to be had, are sometimes placed on the top of the ridges to preserve them from cold drenching rains, frosts, and rough winds. The latter are very injurious to the crop. It takes an immense quantity of manure to make any extent of these

ridges, and by the time they are "spent," it is very much reduced in bulk and substance. Of all market-garden crops this is the most expensive and uncertain; some may grow them for years without a check, and all at once they may some season be a complete failure. A famous grower in the vicinity of London, who grew them for many years most successfully, a few seasons ago made up his ridges as before, treated them the same, and was in full expectation of a fine return. From some unaccountable cause, however, they became a total failure that year, by which he lost no less than about £500.

ONIONS.

These are only grown for home use and for early salading. For this purpose, slight hotbeds are raised in the end of January, and in the first of February some of the White Tripoli Onions are sown for drawing young. This favourite variety is the one most grown in market gardens round London, as it produces a longer white neck than any other kind, and is of excellent quality. Before sending it to market it is washed, rubbing the outside skin off in the operation, and tied into little bundles.

RADISHES.

These form one of the principal spring crops. In summer Radishes are in general not so good; but here, even as late as the end of June, they are excellent, a circumstance doubtless to be attributed to the moist state of the soil, caused by irrigation. Radishes, after the end of April, prefer a cool, moist, and partially shaded situation. The first crop of these is sown as early as the beginning of February, out of doors, in deeply-worked, well-manured ground, made into four, five, or six feet beds, with a foot alley between them. The surface is broken a little, and the seed is sown broadcast, and raked in, and the beds are then rolled by means of a roller drawn by two men, each walking in the alley on each side of the bed. After being sown, the beds are covered with litter until the plants come up, when the litter is removed in the morning, but replaced in the evening. Birds are great enemies to this crop, and for this reason a boy is kept at each plantation to frighten them away. The varieties of Radishes grown are the white and red turnip-rooted and the long red salmon. Successional sowings are made every fortnight, or, in fact, as often as ground can be had for them, manured and dug. Coverings of litter are employed from the time of sowing until the young Radishes germinate, for they are not only useful in protecting the seed-bed from cold at night, but also prevent birds from making a prey of them by day. Cauliflowers, Lettuces, &c., make a good succession to this crop, and Spinach and Turnips are also often made to play the same part.

(To be continued.)

THE FOREST OF DEAN.

TILL iron took the place of oak, the trees of our noblest forest were devoted to the sea. At least half our historic ships were born between the Severn and the Wye. It is a strange country still. The Forest of Dean represents a time when all the land in Gloucestershire belonged either to the Church or to the Crown. It formerly crossed the river until it met the southern spurs of the Cotswolds. Even now, though it has receded before farms and fields, it comprehends nearly the fourth part of a large and populous county, without containing any collection of cottages within its bounds that can presume to call itself a town. A century ago it must have been a country of savages. Its churches and its schools are importations made within living memory. The people, who have by no means lost all their peculiar characteristics, seem to have lived almost wild among the woods, even in quite recent times, making frequent raids upon the neighbouring farmers' flocks, and, like the men of Robin Hood, waging chronic war upon the King's red-deer. There are no such forest depths to be found in England—no such oaks to be found in the world. You may lose yourself in acres of foxglove and bracken that grow as high as young trees. It is very extraordinary that this remarkable and picturesque region, filling as it does so large a district of Western England, should, except by the Admiralty and the iron-masters, be so utterly ignored. The passage of the Severn seems to keep back the army of landscape painters as it did the legions of Caesar. That can be the only reason, for it is the only part of England left where English forest scenery is in its full perfection, and holds its ancient supremacy. I have said that west of the Severn there are no towns. The capital of the forest is the Speech House, the Forest Hall, where the verderers still hold their courts of attachment, and are supposed to perform the other functions of justice according to forest law, which treated men and women as of no account in comparison with "vert and venison." It is a solitary lodge, miles away from any cluster of habitations, and it is the centre of that English poetry which is written upon

the leaves, not of books, but of trees. It has no historical associations of which I ever heard—no outlawed earl has left his traditions to take away the feeling that we are in the Britain that the Druids knew. We do not so much look for fairies among the ferns, though no doubt they are there, as to meet with Arviragus and Guiderius. Imogen's road to Milford laid straight through these oaks, and it is my own opinion that it was here where was first performed the sylvan part of "Cymbeline."

The character of the Forest of Dean is as English as that of its spreading oaks themselves. No forest is equal in beauty to an oak forest; and no such oak forest is to be found elsewhere.—G

THE HOUSEHOLD.

THE CHANTARELLE.

(CANTHARELLUS CIBARIUS.)

The Chantarelle grows sometimes sporadically, sometimes in circles or segments of a circle, and may be found from June to October. At first it assumes the shape of a minute cone; next, in consequence of the rolling in of the margin, the pileus is almost spherical, but as this unfolds it becomes hemispherical, then flat, and at length irregular and depressed.

When young its stalk is tough, white, and solid; but as it grows this becomes hollow and presently changes to yellow; tapering below, it is effused into the substance of the pileus, which is of the same colour with it. The pileus is lobed, and irregular in shape; its margin at first deeply involute, afterwards when expanded, wavy. The veins or plaits are thick, sub-distant, much sinuated, running some way down the stalk.

Chantarelle (*Cantharellus cibarius*). Woods, autumn; rich golden yellow; diameter, 2 to 4 inches.

The flesh is white, fibrous, dense, "having the odour of apricots" (Purton) or of "plums" (Vitt.) The colour yellow, like that of the yolk of eggs, is deeper on the under surface; when raw it has the pungent taste of pepper; the spores, which are elliptical, are of a pallid ochre colour (Vitt.)

"This fungus," observes Vittadini, "being rather dry and tough by nature, requires a considerable quantity of fluid sauce to cook it properly." "The common people in Italy dry or pickle, or keep it in oil for winter use. Perhaps the best ways of dressing the Chantarelle are to stew or mince it by itself, or to combine it with meat or with other funguses. It requires to be gently stewed, and a long time to make it tender; but by soaking it in milk the night before, less cooking will be requisite" (Badham).

Fresh Strawberries at Christmas.—Can any of your correspondents inform me how strawberries are preserved so as to have them fresh at Christmas? My employer has had some at that time which, he told me, had been kept in an ice house; they were, he said, perfectly fresh.—W. T.

Tomato Catsup.—Boil one bushel of good tomatoes until soft, then squeeze through a fine wire sieve; add half a gallon of vinegar, one and half pint of salt, two ounces of cloves, a quarter of a pound of allspice, one and half ounce of cayenne pepper, three tablespoonfuls of black pepper, and five heads of garlic, skinned and separated; mix and boil three hours, or until reduced one-half, and bottle without straining. We have used excellent catsup made from this recipe. The garlic may be omitted by those who do not desire its flavour, without injury.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.

PRIVATE GARDENS.

Conservatories.—On Fuchsias and Japan Lilies lie our principal dependence in the way of flowering plants for conservatories and show-houses at this season of the year. Gladioli in pots are also very ornamental indoors, as are also the different kinds of Bell-flowers, especially *Campanula pyramidalis*, which is at present everywhere beautifully in bloom. *Humea elegans* is likewise a useful plant in conservatories. Annuals such as *Schizanthus*, *Zinnias*, *Celosias*, *Balsams*, *Gomphrena globosa*, and several kinds of *Amarantus*, also contribute considerably to the decoration of these houses. Where *Amarantuses* are wanted for succession they are kept in frames, and are repotted as they require that attention, taking care, however, not to over-pot them. *Trachelium caeruleum* is one of the most useful of plants for flowering. In order to keep up a succession of *Balsams* a reserve stock of them is kept in cool pits or frames; from these the blooms are then picked off as they appear, until within a week or two of their being wanted for use. Hard-wooded plants removed outside to mature their wood and to make room for gayer subjects, are being housed in some cases to save them from the drenching rains which we are now experiencing, and where they cannot be got indoors the pots are raised a little off the ground, so as to allow the water to run freely through, thus preventing, to a certain extent, saturation of the soil. Show and fancy *Pelargoniums* are now cut over, some of them pretty well into the old wood, and such as are the most shapely, to a joint beyond that to which they were cut back last year. They are then placed on a shelf, and are kept dry, or laid on their sides out of doors.

Stoves.—Encouragement of growth is not now so much the object aimed at as maturation of the wood produced. For this purpose no more shading is used than is absolutely necessary; canvas shadings, therefore, which are movable are much more convenient than either frosted or white-washed glass. Among the gayest plants at present in Stoves are *Allamandas*, which in all cases blossom best when their roots are allowed to ramble in some bed or border of good soil, and when their shoots are trained along the roof. Thus circumstanced they give more satisfaction than when tied around pot trellises. Of *Achimenes*, *Gloxinias*, and other *Gesneraceous* plants several are still in bloom, and such as are done flowering are laid on their sides to prevent their roots becoming injured by drip; such *Gesneras* as *exoniensis*, *zebrina*, and others of that section, receive encouragement for bringing them in in succession; they are admirable for indoor decoration. In repotting these, the soil is not shaken from the roots, the crocks only are removed. As some of the earlier started *Caladiums* show symptoms of decay, they are removed to some out-of-the-way place and gradually dried off. Some venture to keep them in a green or growing state throughout the winter, but that is not good practice, though occasionally the plan may succeed. Plants of *Clerodendron Kämpferi* that have done blooming are set aside and gradually dried off, whilst those coming into bloom are supplied occasionally with manure water. This *Clerodendron* strikes freely from cuttings of mature wood in spring in a brisk heat. Those put in last spring are now strong, and are being repotted in six-inch pots, and kept in a stove temperature. Rotten manure, yellow turfy loam, a little peat, and a good admixture of sharp sand suit them admirably.

Pits and Frames.—These are becoming filled with cuttings of *Heliotropes*, *Verbenas*, and some of the finer kinds of *Geraniums*. For *Ageratum*s, *Gazanias*, and *Calceolarias* there is yet time enough; indeed, they are seldom put in until the others are rooted, lifted, and potted, or put thickly into boxes. *Chrysanthemums* are, for the most part, placed in sheltered positions on a bed of ashes, out of doors; still, however, a few are kept in frames, especially young plants, to which plenty of air is given. Many of the most forward *Cinerarias* now need a shift from small pots into four or six inch pots, using a good deal of well-seasoned rotten manure in the compost. Seedlings are repotted as they require it. A sowing of herbaceous *Calceolarias* is being made; some prefer to sow late and to encourage the seedlings for a while with heat, whilst others sow earlier and treat them more hardily. *Auriculas* are being repotted and placed in frames that look to the north. *Cyclamens* are also repotted and placed near the glass in frames or pits, and syringed every day. A gradual increase of moisture is given at the root. *Pansies* are propagated by means of cuttings inserted in sandy soil in frames, and well shaded for a time. Ten-week *Stocks* are sown in pans of light soil in cold frames, for winter blooming. A few *Violets* for forcing are being potted, and placed in airy frames.

Flower Garden and Shrubbery.—The season for propagating *Geraniums* and plants of that kind has again arrived; the cuttings

are taken from the outer edges of the beds, or where they can be had stout and stably in constitution, and they are inserted in warm borders, without shade or other covering. Bedding *Pansies* are being increased by means of side-shoots taken off with some roots attached to them, or by lifting the entire ball of roots and separating it into divisions, each of which forms a new plant. In the case of *Gladioli* that have done blooming, the flower spikes are cut over just below the place where the first flowers opened. The points of *Hollyhocks*, and likewise their laterals, that are growing too tall, are pinched out, and, where time can be spared, the plants should receive a good watering with manure water, as should also *Dahlias*. Seeds of *Tropaeolum canariense* are now being gathered; also seeds of ordinary *Nasturtiums*, in a green state, for pickling. *Roses* are still being budded, though some have already finished that operation. In budding, a single longitudinal cut is preferred by some to that in the form of a T; but it has this disadvantage, that it takes longer time to do than the T system does.

Indoor Fruit Department.—Shifting such *Pine-apples* as require that attention is being carried on with as much expedition as possible. The plants shifted are plunged in a bottom-heat of about 85°, and no water is given them until they begin to form fresh roots. Plants that are setting, or have just set their fruit, have some good fibrous loam placed around the necks of the stems, so as to encourage the emission of new roots. *Muscat Grapes* require a brisk temperature to ripen them well, and afterwards proper means are taken to thoroughly ripen the wood. Second crops of *Figs* promise to be good; abundance of water is given them, and syringing is still continued. To *Melons*, a high temperature is maintained and a little air is kept on night and day; those ripening require the border and atmosphere to be kept rather dry. *Cucumbers* are still in good bearing. Some are now lime-washing their pits, making up new borders, and thoroughly overhauling matters, previous to the approach of cold weather. Seeds for winter-bearing plants are now being sown, but another sowing will still be made to come in a little later. Fresh *Mushroom* beds are being made in cellars, dark sheds, and similar places. Those made up last month are scarcely old enough yet for spawning.

Hardy Fruit and Kitchen Garden.—Budding of *Pears* and *Apples* on the T system is still proceeded with; budding of stone fruit has been finished. Where earwigs are troublesome to wall trees, traps are laid for them amongst the branches; they consist of dried hollow stalks, which are frequently examined, and all insects found in them are destroyed. *Strawberries* layered in pots are now being separated from the parent plants and repotted, *i.e.*, if their present pots are filled with roots. Those for making the main outdoor plantations only await ground becoming empty for their accommodation, so well established have they already got. The weakest of young shoots springing from the *Raspberry* stools are removed, preserving only the strongest, which, if getting very tall, have their points pinched off. In the kitchen garden the surface of the soil is loosened with the hoe as often as time will permit. It is a too common practice to rake the ground amongst crops after hoeing, with the view of giving it a neat appearance. This should only be done in cases where rank weeds want removal; but these, on the other hand, should never have been allowed a footing. In market gardens, rakes are only used for breaking the surface of the soil, in order to prepare it for the reception of seed. The first planted *Celery* crop is being earthed up a little; the main late crop has just been planted. *Endive*, sufficiently advanced, is tied up to blanch, or is covered over for the same purpose. Some are being planted in warm, sunny positions; a sowing for a late crop has just been made. A small sowing of *White Stone Turnips* is being made for spring use. *Broccoli* is being planted out, as are also *Cabbages* for *Coleworts*, advantage being taken of the moist weather which we are now experiencing for the operation. Some *Cabbages*, such as the *Red*, *Early York*, *Fulham*, &c., were sown the last week of last month, and the main sowing made the first or second week of this one. *Lettuces* are being tied to "heart"; a sowing of *Angelica* is now being made. Ground is being prepared for the main sowing of prickly *Spinach*; two sowings of which—one about the first and one in the latter end of the month—will keep up a good supply throughout the winter. *Corn Salad* for the winter supply is also sown. The *Onion* ground for the winter supply is being prepared. *Late Peas*, in addition to the moisture they get from rain, are sometimes given a good soaking of manure water. All kinds of *Onions*, as they show signs of ripening, are lifted and laid out to dry, or are tied up in bundles and stored in dry sheds. *Pot* and *Sweet Herbs* are also cut over, tied into little bundles, and hung up to dry.

NURSERIES.

Indoor Plant Department.—All plants which require a shift get it immediately, so as to have their pots well filled with roots before the winter sets in. Young *Azaleas* and *Bouvardias* are being tied

into the shape which it is intended they shall assume. In the case of Azaleas, however, properly managed young nursery plants seldom require any tying, the pinchings which they receive throughout the summer being generally sufficient to convert them into shapely plants. Young Camellias, for grafting on next year, are now set out of doors, so as to mature the wood which they have made in warm moist houses; others are still being grafted. *Pereskia* plants for grafting *Epiphyllums* on are kept near the light in a cool house; about the middle of this month, a good many of them will be grafted. Young plants of *Cytisus racemosus* that made their growth under glass, and which had received three successive pinchings during that period, are now set outside, so as to mature their wood; they are now, as may be imagined, fine stubby plants. Heaths of various descriptions have just been potted and replaced in cold frames. Mats are thrown over them for a time until they take to the new soil; strong plants of them that had been previously potted this year are arranged into order outside, and when they can be placed in frames, they are protected from heavy showers by placing the lights over them. Air is, however, given them by means of tilting the lights.

Outdoor Department.—The last fortnight has been a busy time amongst young fruit trees, some being engaged in training, others in budding them; many are affected with aphides, which this year seem unusually troublesome; a cure for them is, however, found in a preparation of hot water, soft soap, Gishurst Compound, and tobacco water, with sometimes the addition of a little soot and sulphur. After this gets cold, men take some in a small vessel, and, with a second-size painter's brush, go over the trees, sprinkling all the shoots with the mixture. Pears and Apples are now being budded; budding of stone fruits and Roses is finished. Into nurseries, rose-budding without the T incision has found its way; but the time it takes to put in the buds without the cross cut is an objection to its use. Fruit trees are still budded in the old way. Shading is removed from Pansy beds, and young Conifers raised in frames are fully exposed. Plants of *Araucaria imbricata* raised from seed sown early last spring, are being taken out of the seed pans and replanted in pans of light peaty compost, placing the plants round the edges of the pans.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

(AUGUST 7TH.)

At this meeting there was a nice collection of different kinds of variegated-leaved *Pelargoniums* and a magnificent display of herbaceous *Phloxes* in pots, from Messrs. Downie, Laird, & Laing. Tricolor *Pelargoniums*, both old and new, were shown in admirable condition by Mr. Turner, of Slough. From Messrs. E. G. Henderson also came another collection of these favourite plants, among which was a good ivy-leaved kind, the foliage of which is conspicuously variegated with white. The prize offered for the best zonal golden tricolor *Pelargonium* was won by Mr. T. Pestrige, Uxbridge, with Sir Robert Napier, a dark zoned kind, very distinct and fine. For the best silver tricolor Messrs. Downie, Laird, & Laing were first with Mrs. Laing, a beautiful red zoned kind, bright and striking. To the same nurserymen was also awarded the first prize for the best golden bronze zonal, the kind being W. E. Gumbleton, a fine dark-brown broad zoned new variety. Of golden selfs few were exhibited; Mr. T. Pestrige took the highest prize with Golden Banner, a compact-growing sort with rosy pink flowers. Among silver-edged kinds, that which won the first prize was May Queen, a close-growing variety, the leaves of which are very deeply variegated. This came from Mr. Turner, to whom was also awarded the first prize for the best nosegay *Pelargonium* in bloom, the kind being Mrs. Quilter, a beautiful sort, with bold rosy pink trusses of flowers well thrown up above the leaves. Prizes were offered for double-flowered zonal kinds, and the first was awarded to a large plant of Victor Lemoine, a beautiful bright scarlet, from Mr. T. Pestrige. A nice group of hardy Ferns in pots was contributed by A. Thompson, Esq.; it contained many fine varieties of *Scopolendrium* and Lady Fern; also a curious form of *Asplenium Trichomanes*, called Moulei, and a finely crested plant of *A. Adiantum-nigrum*. Along with a collection of ornamental-foliaged plants from Mr. Bull was a fine group of Arums, remarkable looking plants, seldom seen in any quantity at exhibitions, though rich in variety and interest. Of *Bertolonia marmorata*, a charming example was exhibited by Mr. Green, gardener to W. Wilson Saunders, Esq., and was deservedly awarded a cultural commendation. Of Orchids only a few were shown, but among them was a very fine plant of *Grammatophyllum Ellisii*, bearing a flower spike on which were forty blossoms. We also noticed a beautiful-flowered plant of *Massevallia Harryana*, and one of *Mesospidium vulcanum*. These, as well as the *Grammatophyllum*, came from Messrs. Veitch. *Peristeria elata*, with two tall flower spikes, came from Mr. Bull; and a fine example of *Cattleya crispa* was shown by Mr. Baxal, Woodford Bridge. Two fine collections of Balsams were furnished, one by Messrs. Lee, of Hammer-smith; the other by Messrs. Smith, of Dulwich. Of *Verbenas* some fine trusses of bloom were shown; and some beautiful spikes of *Gladioli* were shown by Messrs. Standish & Co., who also furnished a basket of

Bouvardia Vreelandii. Both single blooms and spikes of *Hollyhocks* were excellent, the flowers being of good colour, large and very double.

Of fruit there was but little. Some good grapes were shown, especially two fine bunches of Muscat of Alexandria, from Messrs. Lane & Son, of Great Berkhamstead, and two of Duke of Buccleuch, from Mr. Wm. Thomson, of Galashiels. The latter were remarkable for size of both bunch and berry. A few nice Peaches, Nectarines, and Plums were shown, also a good many sorts of Gooseberries. A good kind of long-podded French Bean was exhibited by Messrs. Lee, called Imperial Long-pod. The pods are from six to eight inches long and very fleshy. Some very remarkable Onions were shown by Mr. Piccorillo, of Wigmore Street. Some idea of their size may be obtained from the fact that the aggregate weight of six of the early White Naples weighed twenty-one pounds, and three Red Naples seven pounds five ounces. The same exhibitor also showed some fine specimens of Garlic.

First-class certificates were awarded to the following:—
Hollyhock Eleanor, a fine double pink seedling, from the Right Rev. Lord Hawke, of Gainsboro'.

Verbena, Mrs. Lewington, a large-flowered rosy-crimson kind.
Fern *Lastrea Filix-mas*, var. *Festingii*, a stiff-growing crisped form of male fern.

OBITUARY.

We have to record, with much regret, the death of Mr. James Ivery, of Dorking, which took place on the 2nd instant, at the comparatively early age of forty-eight. For years he had been an exhibitor at our metropolitan shows of hardy ferns, of which he had a grand collection. He was also a most successful raiser of Indian azaleas, and to him are we indebted for many of the very best varieties of that plant which our gardens at the present day contain.

COVENT GARDEN MARKET, August 9th.

Flowers.—*Fuchsias*, *Balsams*, zonal *Pelargoniums*, both single and double, *Cockscombs*, and *Lilies* are now plentiful. In addition to *Japan Lilies* and blue African *Lilies*, there are several nice little plants of the *Indian Lily* (*Vallota purpurea*) with fine flower heads, each consisting of from two to seven blooms. *Gladioli*, in six-inch pots, form a conspicuous feature, and besides those in pots there are immense quantities of cut blooms of *Brenchleyensis* and other showy kinds. Musk, in small pots, is furnished in abundance. *Creeping Jenny* (*Lysimachia nummularia*) is, owing to its tenacity of life under adverse circumstances, a great favourite with window gardeners, and of this there is generally a good supply. *Lobelias*, especially *L. speciosa*, are also favourite pot-plants, as are likewise *Heliotropes*, dwarf *Asters*, *Lantanas*, *Zinnias*, &c.

Fruits and Vegetables.—Of fruits, those from the open air are not only scarce, but they are not of first-rate quality. Pine-apples, both Queens and others, are supplied in good condition. Melons are not remarkable, as a rule, for quality; but Cucumbers, especially those from pits, are very good. Grapes are excellent, Hamburgs being the favourite black sorts. Amongst white kinds we noticed a basket of Duke of Buccleuch, the individual berries of which are very large. Plums, Peaches, Apricots, &c., are for the most part imported, but there is also some good English indoor-grown fruit of all these sorts. Tomatoes are now plentiful, but none come yet from the open air. Onions, Turnips, Cabbage, Vegetable Marrows, and Potatoes are also abundant. French Beans, of which there is a fine crop this season, are now taking the place of Peas, which are getting scarcer than they have been. Gherkins are plentifully supplied, and young Celery has also made its appearance. Small salading continues to be furnished, and includes Lettuces, Onions, Radishes, Mustard, Cress, Lamb's Lettuce, Beet, and Endive.

PRICES OF FRUIT.

	s. d.	s. d.		s. d.	s. d.
Apples half sieve	2	0	to 3	0	15

THE GARDEN.

"This is an art
Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

"SCIENTIFIC MEN."

We are glad to notice that the Premier protested, in his speech on the Hooker and Ayrton affair, against the practice, common among students of natural history and other branches of knowledge, of describing themselves exclusively as "scientific" men. "Scientific men as they are called by the exclusive appropriation of a title which I must protest against," said Mr. Gladstone. If the term has any meaning at all it must mean men of knowledge, as the word science simply means knowledge. Therefore it is absurd for one or more classes of students or workers to lay claim exclusively to the term "scientific." Of all terms now in use in our tongue there is none that has led to so much confusion among the dim-seeing and the ignorant as this. And it is much to be regretted that the very men who labour most in the interests of knowledge should be responsible for using it so much. In our own art one may take up some family of plants or trees, grow them, and be perfectly conversant with them in every way as well as with their nomenclature, and yet lay no claim to be considered a scientific man. On the other hand, some student who betrays a taste for botany, dries plants, writes, perhaps, a few manuals concerning the naming or classification of the plants which the cultivator grows, and eventually settles into a botanical chair, is, of course, a "scientific man." For our convenience it is desirable that plants, like everything else, should have some name by which we may speak of them; it is most desirable that they should be classified in a natural and convenient manner, and we desire to render due honour to all who devote their lives to such necessary work; but we protest, as Mr. Gladstone did, against any one class of students appropriating the title to themselves. All are but labouring at "parts of one stupendous whole"; there are only differences of degree between all seekers after truth. This is, of course, evident enough to all clear-seeing workers in every branch that lays claim to the distinction of knowledge, and we hope they will endeavour to spread a more modest and a juster view of the matter among their feebler and more narrow-minded brethren.

NOTES OF THE WEEK.

— *Datura Wrightii* is now producing its handsome long tubular double flowers somewhat freely in the sub-tropical garden at Battersea Park.

— *Jubæa spectabilis*, supposed to be the hardiest of the palms, is now thriving fairly in the open air at Glasnevin, but it has not as yet had a sufficiently long trial. It is probable that our sun is too feeble to enable it to make a vigorous growth.

— Among hardy trees perhaps the finest in flower at present is *Catalpa bignonioides*, three fine specimens of which may be seen on a lawn at Cromwell House, Mortlake, the residence of Mr. James Wigan.

— A FINE plant of *Hydrangea quercifolia*, a splendid free-flowering shrub, is now blooming at Messrs. Veitch's nursery at Coombe Wood. The specimen is about four feet high, and is producing its large panicles of pink-tinged white flowers in abundance. This fine shrub should have a place in all collections of hardy plants.

— At a meeting of hot-water apparatus manufacturers, held on Wednesday last in Kettlewell's rooms, King Street, Covent Garden, a joint protest was drawn up against the decision of the judges at Birmingham, by which they assigned the gold medal to Messrs. Hartley & Sugden, of Halifax, without, it was considered, sufficient and satisfactory grounds for such award, and, as it appeared to the meeting, against the evidence of true excellence and in violation of the regulations laid down by themselves for the conduct of the trials; which award, therefore, was believed to be unlawfully assigned, and ought to be withheld, or, if given, to be withdrawn. A dozen reasons

were advanced in favour of a reconsideration of the whole matter, which will doubtless be brought under the notice of the judges by whom the award was made. The Royal Horticultural Society wish it to be clearly understood that they had nothing to do with the awards made at Birmingham to boilers, nor the appointment of the judges, neither was any medal of the Society given to the competitors.

— THE showy American aquatic plant, *Limncharis Humboldtii*, is now flowering profusely in a tank in the open air at Glasnevin. It is accompanied by the interesting *Trapa natans* (the Water-chestnut), which is so rarely seen in our botanic gardens.

— A PLANT of the *Cocoa* (*Theobroma*) is now bearing its large dark orange coloured fruit in one of the stoves at Glasnevin. It has been fruited in a large pot. The Mango is also fruiting freely in the same garden, which is in all respects in fine condition just now.

— WE noticed the other day at Messrs. Rollisson's nursery, Tooting, imported plants of *Venus's Fly-trap* (*Dionæa muscipula*); likewise a fine importation of the yellow Pitcher plant (*Sarracenia flava*), also growing strongly.

— ONE of the finest hardy grasses at present in flower is *Sorghum halepense*, a noble plant of which may be seen at the Exotic Nursery, Tooting. It stands some four feet in height, and is producing a profusion of graceful panicles of reddish-brown or purplish flowers. Tufts of it would look well isolated on turf.

— A LARGE batch of the beautiful *Lilium speciosum* (*laucifolium*) and its varieties has just commenced to bloom in Mr. Barr's trial grounds at Tooting. This fine lily is quite hardy and thrives perfectly here, as well as in several other places out of doors round London.

— A FINE hybrid *Gaillardia*, named *Telemache*, is flowering at Messrs. Henderson's, Wellington Road. It has a free-branching habit and flowers abundantly. The disk and lower part of the florets are of a dark-reddish colour, while the tips of the latter are bright orange-yellow.

— THE potato disease, we are sorry to hear, has appeared in many places with unusual virulence, and advantage is being taken of the dry weather we are now experiencing to take up early sorts as fast as possible. Not only from different districts in England, but also from Scotland and Ireland, does such news reach us.

— NEW JERSEY never was more luxuriant than at present as regards fruit. The cherry crop has been very heavy, unusually so, and peach trees are bowing to the ground with the weight of their fruit. The peach crops in South Illinois are also said to be prodigious.

— MANY of the proprietors of the southern vineyards of France, where the vines have been attacked by *phylloxera*, have it in serious contemplation to substitute the cultivation of the ramie or China grass for that of the vine. There are, on the other hand, it is said, indications of an early and good grape season in the vine districts of Switzerland.

— THE little beds adjacent to the so-called "rockwork" at the end of the Serpentine in Hyde Park, which in former years formed a chief object of attraction in that part of the park, remained empty until the morning of Friday the 9th instant, when they were filled with plants that, if wanted to make satisfactory growth out of doors, should have been planted at the very least two months ago. We shall be curious to see how these late-put-in plants comport themselves.

— It will doubtless interest our readers to know that Mr. Thomas Jones, gardener to the Right Hon. Lord Leconfield, at Petworth Park, Sussex, has been appointed to succeed the late Mr. Rose as gardener to her Majesty at Frogmore. Mr. Jones has been nearly fifteen years at Petworth, where the gardens bear ample evidence of his skill as a cultivator. In his earlier days he was at Crewe Hall, Trentham, and other good places. Such lengthened practice, therefore, cannot fail to eminently qualify him for the important position he has been selected to fill.

— STEPNEY GREEN, which has just been laid out as an ornamental garden, was opened to the public last Saturday. It is enclosed by a handsome iron railing, seven feet six inches in height, which springs from a red brick base about two feet high, with a stone coping. Several old cross thoroughfares, the greater number being rights of way, intersect the ground; and whilst these have been preserved by distinctive railing and boundary marks, they have not interfered with the appearance of the garden. At the upper end of the ground is a large number of full-grown trees, which have been preserved in their entirety, thus giving to the newly-formed garden a maturity of appearance which seldom belongs to works of this character. A lodge and gardener's residence are amongst the buildings to be erected within the grounds.

— A HOUSE recently built in the College Gardens at Dublin has been glazed with violet glass, so we shall probably hear more of the behaviour of plants beneath it. General Pleasanton's report of its virtues requires confirmation.

— *SEDUM CYANEUM*, a pretty and by no means common species of Stonecrop, is now in bloom in a border at the Hale Farm Nursery, Tottenham, where also may be seen patches of the fine *Sedum Eversii*, which is producing its corymbs of purplish flowers more freely than we have hitherto seen it do.

— SCARCELY less beautiful than the wallflower in early spring is the red Valerian on some old ruins and walls at present. On some of the old ruins in Wales it may be seen established here and there, and will probably some day be as commonly seen on such places as the wallflower. It is seen in greatest perfection naturalised on stony banks or old walls, &c.

— AT Milan, during a hurricane which has recently visited that city, the strongest trees were torn up by the roots, and among those destroyed was the majestic elm planted three centuries ago by the Archduke Ferdinand. About fifty planes were levelled to the ground on the Lazaretto.

— *ARUNDO CONSPICUA* is just now, and has been for some weeks, one of the most beautiful objects in our gardens, especially in the milder seashore and southern districts. It grows from seven to nine feet high, and blooms beautifully long before the Pampas-grass begins to send up a shoot. We recommend the plant for every garden or pleasure-ground in the milder parts of the country for which hardy ornamental plants are sought.

— A FINE tuft of the American Pitcher-plant (*Sarracenia purpurea*) is now in perfect health in the bog garden at Glasnevin. It has been in the same position for the past ten years; therefore there need be no doubt whatever that it is as hardy as any native bog plant. It should be planted in wet (not merely moist) peat, and in a sunny open position. The *Darlingtonia* is making fair growth in the same bog, but has only been out a few months.

— THE dwarf *Acæna microphylla* is this year producing its crimson globular heads of spines more freely than we have ever before seen it in the neighbourhood of London; in fact, a plant of it that we noticed at Kew was completely covered with them, and in this condition it presents a very striking appearance. It is a capital subject for the margin of a border, and it will likewise be found a useful plant for rockwork. The plant, flower-heads and all, is little more than two inches high.

— Two pretty and distinct kinds of Snapdragon are now in flower in the neighbourhood of London, viz., *Antirrhinum siculum* and *A. rupestre*. The first is at Mr. Parker's, Tooting; in habit and colour of flowers it somewhat resembles the common Snapdragon, but it has very narrow leaves. The latter is in flower at Mr. Ware's, Tottenham; it has a dwarf and somewhat prostrate habit, and produces whitish flowers with yellow streaks, the lip being of a flesh or pinkish colour.

— IN the College Botanic Garden at Dublin a dozen or more specimens of the Californian Soap Plant (*Chlorogalum*) are now in flower. The plant is quite hardy there, and seems to thrive better than we remember to have seen it on the foothills of the Sierras, where it abounds. The flower stems reach a height of ten feet, and at first sight look like gigantic specimens of *Anthericum ramosum*. It is not ornamental; useful it may prove if soap shares the fate of some of our other indispensable commodities and goes up in price.

— SOME of the most remarkable grapes we have ever seen were shown at the Royal Horticultural Society of Ireland's show at Salt Hill on the 8th instant, by Mr. Roberts, gardener to Colonel Bury, Charleville Forest, Tullamore. One bunch of Muscat of Alexandria looked like a large bunch of the Syrian, and weighed, so we were informed, seven pounds. Other grapes were shown by the same exhibitor in equally fine condition, and proved clearly that Mr. Roberts is in the very first rank of grape-growers.

— THERE is some interesting matter to reward the patient reader of the Blue-book containing the Hooker and Ayrton correspondence. We have all heard of the man who was so thin that "you could see through him," but accustomed as we are to surprises nowadays, all of us must be alarmed to find it stated in an important official communication that the vegetation of the Palm-house at Kew presents so ghostly an aspect that the Museum beyond the lake can be seen through it. This statement will be found at page 99, where, in a letter to the First Commissioner, Dr. Hooker says that the leaves on the plants in the Palm-house are so spare "that the pots and tubs are everywhere seen; and a person standing outside the north wing can see the Museum building through it all along;" that is to say, through sixteen parallel rows of plants.

— THE most beautiful flowering tree we have for a long time seen is a healthy specimen of *Gonista ætensis*, now in bloom at Glasnevin. It may be likened to a slender-twigged *Cytisus* with a habit like that of the weeping willow. We feel sure that any of our Irish readers who may be led by this notice to visit the tree will be very likely to seek it from their nurserymen this autumn.

— LOVERS of interesting hardy herbaceous plants would be pleased to see the healthy tufts of *Calceolaria violacea* now coming into flower in the Royal Botanic Gardens at Glasnevin, near Dublin, where this *Calceolaria* is perfectly hardy. It is usually planted on warm borders of light rich soil, and allowed to grow against the walls of the houses.

— THE singularly beautiful *Philesia buxifolia* has bloomed freely in the Royal Botanic Gardens at Dublin this year, and the last flowers are now upon it. To those who do not know it, it may be described as a low box bush with a tendency to climb, but bearing flowers very like those of *Lapageria rosea*. It is perfectly hardy, and at Dublin grows in a moist peat border at the foot of the north wall of one of the ranges of glass, and in a corner where it gets little if any sun. The specimen at Glasnevin was one of the most beautiful objects we have ever seen in a garden.

— ONE of the principal salesmen in the Grand Row, Covent Garden Market, informs us that it is impossible to offer any opinion as to the quality of home-grown fruit this year, for it has been so scarce that throughout the whole season he has only seen about four dozen Apricots, and other outdoor fruits are proportionately scarce. He gets his principal supply from the Channel Islands, and, taking into consideration packing and carriage, prices must necessarily be high. Jargonelle, and other early Pears, are said to be very poor indeed.

— NEXT to the Tritomas the most conspicuous herbaceous plant in flower during the present week is the large *Lobelia Tapa*. It is rarely seen in London gardens, and probably perishes on cold soils, but in rich and well-drained ones in mild districts its tufts are now four or five feet in diameter and as much high, and it forms huge leafy tufts like a great *Salvia*. It is peculiarly suited for association with the nobler autumn flowering herbaceous plants, where it thrives well. A good example of it may be seen at Tottenham, where, we are informed, it has stood out of doors for the past three seasons.

— THE windy weather on Saturday and Sunday last played sad havoc with some of the sub-tropical plants in Hyde Park, particularly plants of the *Musa Cavendishii*, the leaves of which were literally torn into "ribbons." The *M. Ensete* did not fare so badly; nevertheless some plants of it were considerably damaged. Among other plants injured were the *Strelitzia* and *Caladium esculentum*, many of the leaves of the latter being either broken off or bent so much that they could not recover. In the more sheltered sub-tropical garden at Battersea, such plants did not suffer so much (although one or two plants of *Musa Ensete* were much torn), but this is owing to the precaution being taken of tying the leaves up. On Sunday morning a very fine plant of *Arancaria Cunninghamii*, planted out in the Temperate House at Kew, had its top blown off, more than one-third of the length of the stem being carried off, and the plant consequently completely spoiled. We should add that the roof-sashes are open in summer.

A Botanical Bore.—"The personal insignificance which makes me hesitate as to the propriety of my asking you to insert a letter from me adds to the value of the testimony I am able to give to the invariable courtesy of Dr. Hooker in ordinary correspondence. More than four years ago, being in necessitous circumstances, I applied to Dr. Hooker for a situation in the library or herbarium, and was very well recommended. I was much disappointed at his reply that there was no vacancy nor likelihood of a vacancy in such a situation as I should be qualified to fill. Afterwards, on visiting the gardens in the summer of 1869, I noticed several inaccuracies in the labels attached to plants there, and I wrote to the Director on the subject, condemning the erroneous labels in the severest terms I could think of. I have now before me the reply which I have received on that occasion, admitting the general accuracy of what I said, and telling me that all labels should be taken to the library for correction before being placed out. Since that time I have always received a courteous reply when I have written to Dr. Hooker, which has not been often. The last occasion was not a month since, when I called attention to an error in the nomenclature of a plant in the herbaceous ground, to which I received a reply by return of post, thanking me for pointing out the error, which should be attended to at once. It is simply incredible that a gentleman so uniformly courteous to one who is a poor man and lightly esteemed, should treat an official superior with less consideration unless provoked by something too irritating for human virtue to sustain."—*J. Gibbs, Chelmsford Museum, in "Times."*

THE KEW AFFAIR IN THE COMMONS.

ON the motion that the Appropriation Bill be read a third time, Mr. Fawcett said that as this Bill appropriated the money voted by the Committee of Supply for the maintenance of Kew Gardens and the payment of the staff, he was strictly in order in referring to the position in which Dr. Hooker was placed. If Dr. Hooker should state that he had not intended to say anything of a personal character in his letter, and if the Government stated no discourtesy had been intended towards Dr. Hooker, the matter, he believed, would be amicably settled. He desired to avoid entering into the matter fully for fear of saying anything which would render a settlement more difficult. (Hear, hear.) Considering Dr. Hooker's public services and the benefit Kew Gardens had been to the country and to India, he believed he was expressing the unanimous wish of the House that nothing should be done likely to deprive the country of the eminent services of Dr. Hooker.

Mr. Osborne.—When the House considers that for Royal Palaces and gardens a sum of £100,000 is expended by votes of this House, I think it not unnatural that we should inquire very strictly into the management of those gardens. Lord Bacon has laid down that a garden is the purest of human pleasures. I come then to ask, How is it that Kew Gardens, in which the public so much delight, have become so fruitful a source of strife and bitterness? The answer is at hand. There is nobody more willing than I to testify to or acknowledge the valuable and efficient services of my right hon. friend the First Commissioner of Works. I believe him to be a valuable public servant; but the style of his rule reminds one of that of the centurion in the Scriptures who said to his servant, "Go, and he goeth"; and I think that it is very unfortunate that he should have been thrown into communication with a man like Dr. Hooker, who, although undoubtedly scientific, may perhaps be at the same time rather over-sensitive. The consequence has been that there has been nothing but heart-burnings, bickerings, and bad feeling between them since these two gentlemen came into official communication, or, perhaps, I should rather say collision. I intend to touch but lightly on the principal points in the dispute. Dr. Hooker writes to the Board of Works to know what his duties and his responsibilities are with regard to the warming apparatus, and the answer he gets is that he is to take his orders from the First Commissioner of Works, and it concludes with the unnecessarily offensive expression—an expression that would cause a man of far less sensitiveness than Dr. Hooker to take fire—"and that he is to govern himself accordingly." Then there is a dispute as to the tropical orchids, and I must say the First Commissioner here shows himself not only audacious, but orchidaceous. A long correspondence ensues upon this subject, and, as has been already remarked in one of these letters, this is the way in which public money is consumed in disentangling the science of botany from business matters. I wish to hold the balance evenly between all parties. I think that Dr. Hooker here acted intemperately. I think he had no right to accuse the First Commissioner of evasion, misrepresentation, and mis-statement. I think that is a very hard thing to say of the First Commissioner, for with all his faults we love him still. After this most extraordinary part of the business there appears a memorandum dated July 24, 1872, which occupies fourteen pages. It is from the First Commissioner of Works as to the management of Kew Gardens, and it contrives to stick additional pins into Dr. Hooker. Let the House, beware lest by reason of this appendix we are to have the South Kensington business over again, and lest at this very time we should be engaged in constructing a Cole-cellar for the growing of tropical plants at South Kensington. I think Dr. Hooker, although a very sensitive man, has much to complain of. I think, further—to reiterate what I said some little time back—that the right hon. gentleman the First Commissioner of Works is a valuable public servant; and, as I wish both gentlemen to retain their stations, I would advise them to read that scene in the "Beggars' Opera," between Peachum and Lockitt, where they each say, "Brother, brother, we are both in the wrong," and let them in future endeavour to forward the public service by keeping on good terms with one another.

Mr. Ayrton.—When he succeeded to his office, the Treasury, and in fact the House of Commons, had long been contending against what was conceived to be a very grave error in the administration of matters connected with works—namely, that the House and the Treasury were constantly led into sanctioning the expenditure of money on works, and after that money was spent it was discovered that they had not got to the end of the work, but were only embarked in its beginning, and that large additional sums were again and again required before it was completed. No one contended against that system more than he had done before he was connected with the Department. Well, it so happened that an estimate being placed before him, a request came from Dr. Hooker to spend more than

double the sum sanctioned for that work. He, therefore, asked for certain information as to how it was that a request had been made for sanctioning a smaller sum, when so much larger a sum was required, and how that fact had not been brought forward at an earlier period, as he thought it should have been in the proper conduct of business. That, however, was proclaimed to be a grave censure on Dr. Hooker. It was nothing of the kind; it was only a request for information on those points. The mission to St. Petersburg was proposed before he was First Commissioner, and he had nothing to do with it; but when a gentleman was so sensitive about the language employed, he must remark that Dr. Hooker was capable of using, in the most gratuitous and uncalled-for manner, language of the most offensive kind. An illustration of this was furnished by the letter he wrote in consequence of the decision at which the Treasury arrived about the proposed mission. The Treasury informed him, through the late First Commissioner, of their decision, without stating the grounds for it; and, not knowing whether the head of the Government, or the Chancellor of the Exchequer, or the whole Cabinet had given the decision, Dr. Hooker wrote most offensively to the Treasury, saying he did not know whether its conduct was due to ignorance, negligence, or disregard of scientific progress. Of course, no notice was taken of the letter of Dr. Hooker, because he was one of those excitable gentlemen who did not make themselves amenable to the ordinary courtesies of society. A gentleman who could write a letter to the Treasury, in which he said "he did not know whether the decision of the Treasury would be regarded as indicating indifference to the position which he held in this country, or an ignorance of the eminent men who had convened the Congress, or a disregard of international courtesies in scientific matters," had no right to be hypercritical on language addressed to himself. Unfortunately, his hon. friend the member for Waterford had thought it right to refer to another topic which he thought might well have been passed over. A number of philosophers or scientific gentlemen thought proper to send a letter to the Treasury with reference to this matter. Those gentlemen claimed for themselves great weight and great authority. No doubt they were gentlemen who were eminent for their knowledge of organic and inorganic matter. They had applied their minds to various branches of natural science, and in consequence thought they were infinitely superior to himself. He did not wish to pride himself upon anything. He was but a humble member of a profession which prided itself on studying and practising a science far higher and deserving far more consideration than the science of organic and inorganic matter, that great science of the law which had so often regulated the relations of man to man and taught people to judge righteously and act justly. Had there been among these professors but one barrister of a year's standing, or even but one pupil of a year's standing, he would have taught them that wisdom which would have astonished them amazingly, viz., the cardinal principle that before forming an opinion on any person's conduct they must be assured of the possession of all the facts. To judge by their practice these gentlemen appeared altogether ignorant of that principle, having arrived at a hasty conclusion on shoddy reasoning and an imperfect investigation of facts. Without troubling themselves to inform themselves of the facts on which alone a proper conclusion could be arrived at, these professors wrote a scurrilous and calumnious libel upon him. He had made some researches as to its authorship, but there appeared great delicacy as to the responsibility for its publication. He thought a correct opinion had been formed that the abuse contained in it was what any public man with duties to perform must expect at the hands of those disappointed with the course he pursued. What was the origin of the controversy? Dr. Hooker was by law a subordinate officer of the Office of Works, the Commissioners alone being, by Act of Parliament, invested with the management of Kew Gardens. By law, therefore, he had no status whatever, but was an executive officer of the Board, responsible to them. The very letter in which he was informed of his appointment stated that he would be required to give his exclusive time and attention to the duties of the office of Director, and to observe strictly such orders as he might from time to time receive from the First Commissioner. The published papers showed that his predecessor, Sir W. Hooker, was subject to the most peremptory orders by the First Commissioner, even in matters which might be supposed peculiarly under his control, as to the cultivation of the gardens and laying out of the grounds. Dr. Hooker had been addressed from time to time in a most peremptory manner, so peremptory that he admitted having been quite disconcerted on making a well-considered proposal on some matters of cultivation because the First Commissioner shook his head at him. There could not be more complete dependence than that. This having been the legal and actual state of things, how could Dr. Hooker complain of his continuing to exercise the power? Now he expected, before the debate commenced, that the Government, having definitely

decided to make no change in the administration of the gardens under the Office of Works, leaving the question open till the erection of the museum, that there would be an end to this contention, and the business would go on as heretofore, Dr. Hooker being regarded, as he had always regarded him, as head of the department, and receiving, of course, from him all the consideration due to his botanical knowledge and the experience he might have gained in carrying on the affairs of the department. Dr. Hooker, doubtless, in a moment of irritation and vexation at finding he was not likely to accomplish his end, wrote a letter to his right hon. friend's private secretary. His right hon. friend at the head of the Government had written a letter which would have satisfied and gratified any one in the public service, but finding Dr. Hooker not satisfied, he went further than he had perhaps ever done on a similar occasion, saying, "You had better go to my secretary, and perhaps he will be able to arrange the matter with you to your satisfaction." To the secretary Dr. Hooker accordingly went, and any one aware of Mr. West's ability, experience, and conciliatory manner must know that nobody better qualified for the duty could have been selected. It was a great thing for a Minister of the Crown to take such trouble to satisfy a person occupying such a subordinate position. What sort of conduct, he should like to know, was it that a subordinate should, in the first place, lodge a charge with an individual in whose keeping he knew it would be wholly confidential, and that, after he had negotiated with the Government on an entirely different basis, he should then endeavour to revive that charge, and, when he did so, never venture to assert one single fact in connection with it? For in the paper signed by those professors, although they made a charge, they did not state the facts by which they said it could be sustained. If he were to do justice to their intelligence, he would say that they never had any facts before them by which the charge could be supported. But if he were to do justice to their inconsiderate conduct, he would say that they were meddling with a business which did not concern them, and with respect to which they did not possess adequate information. Let the House just observe the nature of this charge, as also of that which had been solemnly preferred against him in another place. Both charges were the very opposite of one another. The charge which had been made in another place was, that he, conscious of his own knowledge and capacity, had been overbearing towards a subordinate officer. Such was the charge which it was attempted to support by those frivolous details to which he had called the attention of the House. But the charge made against him by Dr. Hooker was, that he had been guilty of evasion and misrepresentation, and of all those errors which were used by a slave to escape from the anger of his master, but which a master conscious of his power was not in the habit of exercising against a slave. If he were a person who was, as had been represented, so overhearing and conscious of his power, he would not have resorted to evasion and misrepresentation, and all those tricks which persons conscious of their weakness found themselves compelled to adopt. But there was, in point of fact, no foundation for the charge. As matters now stood, a grave charge had been made against him by a subordinate officer, against which it was incumbent upon him to defend himself, and the ultimate result of which he would not now anticipate, more especially as it was not his intention to take any part in its final solution. The charge had been made against him in a communication to the First Minister of the Crown, and his duty in the matter was performed when he drew his attention to it, and he had no doubt that the right hon. gentleman would perform his duty also with respect to the subject. No doubt Dr. Hooker had performed important duties as a botanist—he distributed thousands of interesting plants to persons who made botany their study, but he had done so in the discharge of a public duty, and it would be a grave reflection upon the botanists of this country if it were to go forth that there was only one person competent to undertake the office now held by Dr. Hooker. He might further add that it would be fatal to the public service were it to be assumed that any person occupying such a position was entitled to censure the conduct of his official superior, and to dictate to the Government under which he held office.

Mr. Gladstone.—I cannot refrain from expressing the deep regret with which I have listened to this discussion. From the first moment I heard of the differences that had unfortunately arisen between my right hon. friend and Dr. Hooker, I felt that the matter was not one in which I was officially bound to interfere in my personal capacity. Indeed, it would be impossible for me personally to undertake the responsibility of settling all difficulties which might arise between Ministers and servants of the Crown acting under their directions. Feeling, however, that much mischief would be likely to accrue were this matter to be allowed to run the usual official course, I did make an effort to bring the dispute to a satisfactory termination. In that endeavour, however, I entirely failed, and my private secretary, Mr. West, full as he is of kindness, also failed in achieving that

object. There was one other subject to which it would have been my duty to refer, and I will just mention it—namely the special charge which has most unfortunately and unhappily been brought by Dr. Hooker against my right hon. friend of "evasions and misrepresentation." That charge is, undoubtedly, a fact of the gravest character. But here I will express a belief more favourable to Dr. Hooker than that of my right hon. friend. That charge was conveyed in a letter which Mr. West very prudently, as I think, treated—I will not say as waste paper—but as a document which ought not to have become part of the communications on this subject. Afterwards, to the great surprise of my right hon. friend, he learnt from leading articles in the newspapers that this charge had been made. He brought it under my notice. I inquired where was it found, and discovered that it was in this private letter. It was a letter written to Mr. West, who was communicated with in his own personal capacity as one actuated by a friendly feeling between man and man. I am convinced—unfortunate as the publication of this letter is—that it is totally impossible it could have been done by Dr. Hooker's agency or permission. I am bound also to add that the charge having been made, the whole House will see that it is absolutely necessary, if it cannot be sustained, that it should be distinctly and unconditionally withdrawn, and that regret should be expressed for its having been made. I feel that it would be the wish of Dr. Hooker himself, and in that hope I will say that I think both these distinguished gentlemen may be able, without painful feeling on either side, to continue their co-operation in the public service. I must say that I think scientific men, as they are called by the exclusive appropriation of a title which I must protest against, have a great susceptibility. It is natural that it should be so. But independent of that, those who are not accustomed to enter into our sturdy conflicts take reproach in a much more serious manner than we who are accustomed to it do. I have heard from my hon. friend the member for Maidstone that, owing to the illness of Dr. Hooker, it was not possible to have a communication from him this day which I had hoped would put an end to this controversy. Dr. Hooker must feel that while this charge stands against my right hon. friend the existence of official communications between them cannot be other than momentary. I do hope that he will be inclined to take a practical view of the question. Those who have heard my right hon. friend are I am sure convinced that his desire is to do his duty, and those who have known Dr. Hooker and his character will, I am certain, have exactly the same conviction of him. Well, let us say to Dr. Hooker and my right hon. friend, if personal matters can be disposed of in the only way they ought to be disposed of—namely, in the way I have pointed out—let us say to them—"Bury in forgetfulness the recollection of those differences," and if that can only once be done there will, I am sure, be no competition between such men except the anxiety of both to do their duty to the public, my right hon. friend exercising his rule with mildness, and Dr. Hooker doing his duty in subordination to my right hon. friend.

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM AUGUST 8TH TO AUGUST 14TH, INCLUSIVE.)

BY OUR OWN REPORTERS.

<i>Æsculus</i>	<i>Delphinium</i>	<i>Liatris</i>	<i>Scutellaria</i>

Plants in this list are almost without exception such as have come into bloom during the past week.

GARDEN DESTROYERS.

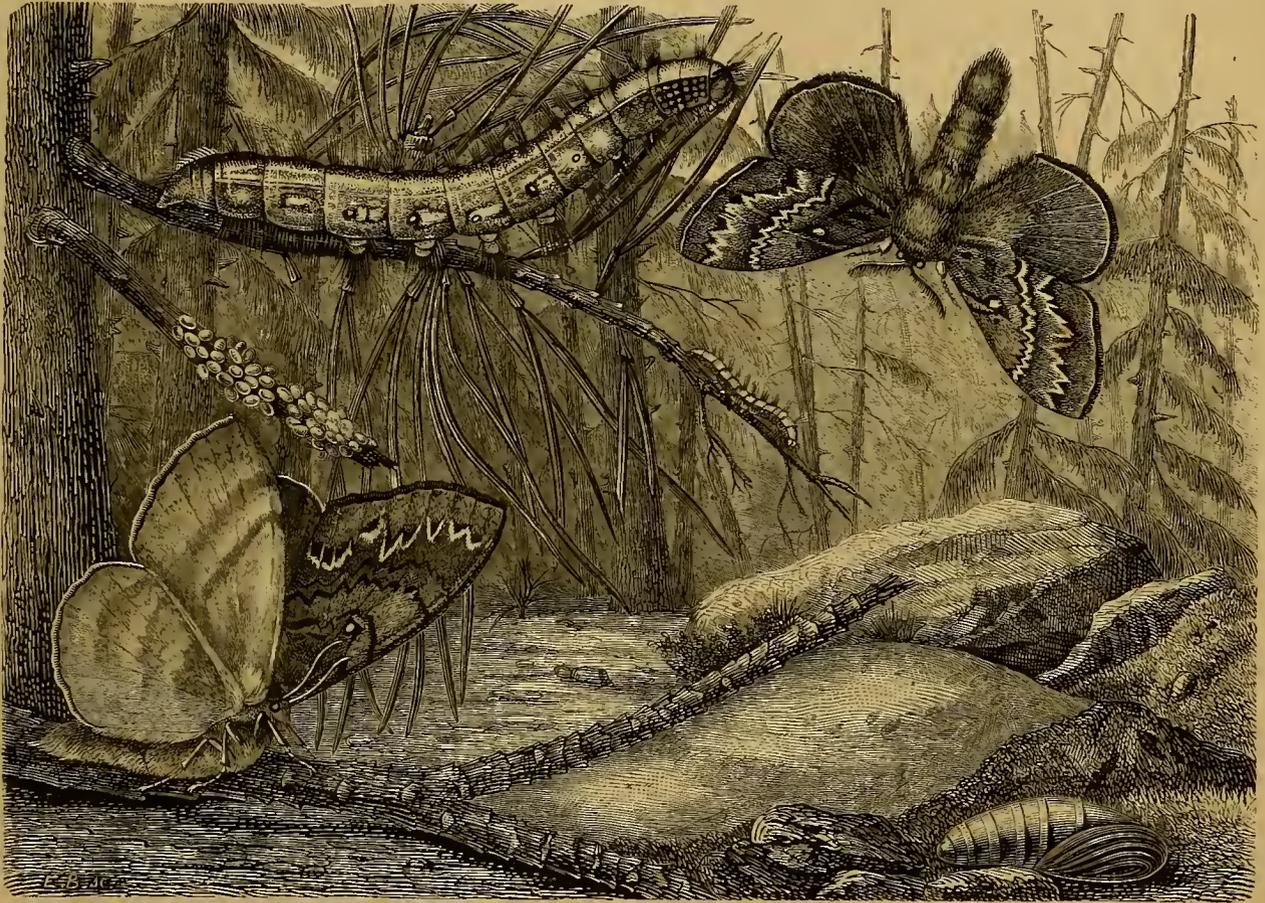

BOMBYX (LASIOCAMPA) PINI.

The moth which we are about to describe would scarcely find a place in our pages were we to confine our notices of insect enemies to those which occur in Britain. But it is our aim to communicate all such information on these matters as may be of interest to the British gardener, whether it relates to Britain or not, and we should ill fulfil the task we have proposed to ourselves were we to refrain from making our readers acquainted with the present species, *Bombyx pini* (with which every one in Germany is familiar as one of the greatest scourges to the pine tree), merely because it has been rarely found in Britain.

This, as it is the largest, is also probably the most destructive

words of Kollar will answer equally well:—"Those who have seen the ravages of the great swarms of caterpillars of this moth cannot sufficiently express the melancholy and lamentable appearance produced on the trees by the injuries they commit." Leaving these irregular periods of abnormal multiplication, we shall simply describe the even tenor of the life of the insect in its ordinary phases.

In the first place the female lays her eggs in July or August. These are of a roundish shape, pale green, and rather large. She lays from one hundred to two hundred, generally irregularly, either in flat heaps or clustered round a twig. This clustering of the eggs round the twig is characteristic of most of the Bombyces. It is the same kind of instinct as that which gives rise to the necklace or bracelet cluster of eggs of the lackey moth or the eggs covered with mouse-coloured fur of the small eggar (*Eriogaster*

Bombyx (Lasiocampa) pini.

of all the insects that attack the pine tree. In north and mid Europe, Germany, Poland, and Russia, it is constantly present, and always doing more or less damage. But now and then some cause stimulates it into unusual fecundity, and then the ordinary course of its life and habits seems to undergo a change and increased power of production to be conferred upon it. The normal course of changes by which the egg, the caterpillar, chrysalis, and perfect insect succeed each other in regular sequence is no longer observed, and eggs, caterpillars of every age, pupæ, and moths occur all at the same time and on the same tree throughout the whole summer. On such occasions we have astonishing accounts of their vast numbers, and we could refer to statistics with long rows of figures showing the number of quarts of caterpillars, cocoons, and moths that have been collected per acre in certain districts. We shall not trouble the reader with these; the simple

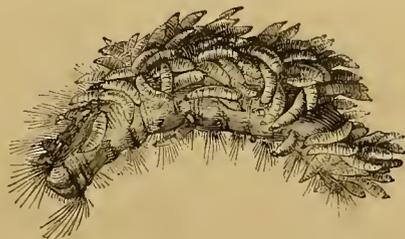

lanestris). The caterpillars take about a fortnight to hatch. As soon as they come out they at once betake themselves to the foliage, which they consume voraciously. By the end of autumn they have reached an inch or an inch and a half in length; but they have to grow to about three times that size before they pass into the pupa state, a full grown caterpillar measuring three and a half to four inches long; and as the cold of winter prevents them feeding during that season, they retire into crevices and under the moss on the ground, and there hibernate. When spring returns they leave their winter quarters and again ascend the trees and recommence feeding. They continue thus occupied until June or July, when they change their skin for the last time and pass into the pupa state. The pupa is about an inch long, and of a dark grey colour in front and dark brown behind, and lies in an oval yellowish web, which is suspended on the bark and bare twigs

of low bushes and trees. They remain there for about three weeks, when the moth emerges.

The colour of the caterpillar is dark grey above with whitish and brown stripes and lozenge-shaped spots along the back and sides. As it gets older the white predominates more and more; it is pubescent or downy, and, besides, bears long tufts of hair on each segment, thickest on the last, varying in colour from reddish or brown to grey. The head is yellowish-brown, and two bluish stripes are displayed lying between the two first segments when the caterpillar bends down its head. The underside is orange-yellow with brown spots.

The colour of the moth is very variable, the chief tints, however, being grey with rusty bands and a brown patch surrounding a white spot on the disk on the upper wings, and reddish-brown under wings. The upper figure in the woodcut represents the male, the lower one the female, both of the natural size. It will be seen that the upper wings are divided transversely by three or four jagged bars. The inner and middle ones are reddish-brown, the outer ones grey. The underside is brownish-grey; the depth and hue of colour varying, however, so much that a long series of specimens is necessary to show its range. It runs from deep claret or rust-coloured red to pale ashy grey.

The special food of the caterpillar is the Scotch fir—Kollar says it confines itself entirely to it and the Austrian pine; but Loudon mentions its attacking the Weymouth pine, and Ratzburg says he has observed it also on the larch and on the spruce. Fortunately, it has a goodly proportion of enemies and parasites that serve to keep down its numbers by attacking it in every stage—egg, larva, pupa, and perfect insect. The eggs are pierced by the *Ichneumon ovulorum*; the caterpillar is attacked by *Microgaster globatus*, the eggs of numbers of which are deposited in its body by the parent flies, and these gradually consume the interior of the caterpillar, carefully abstaining at first from the more vital parts (which are doubtless avoided as being tougher, less juicy, or less palatable), but at last they attack them too, when they and their "host" are nearly mature. The caterpillar then succumbs, and the larvæ of the *Microgaster* emerge from the body of their victim and spin their cocoons, and pass into the pupa state on the field of battle, that is, on the body, or, we should rather say, empty skin of the caterpillar. Our figure shows them so clustered

Pupæ of *Microgaster globatus* on the Caterpillar of *Bombyx ipni*.

round the theatre of their labours or scene of their past life, and will give the reader some idea of the numbers which attack and pass the first stage of their existence in a single individual. Various other ichneumons perform a similar task, as *Pimpla mussii*, *P. graminellæ*, &c. The pupa is in a like manner attacked by *Anomalon circumflexus*, *Pimpla instigator*, *Ichneumon puparum*, &c., and from the moths, in like manner, proceed *Tachina bimaculata*, *Musca stabulans*, *M. 5-vittata*, and others. It has been said that when this *Bombyx* increases so much as to become seriously injurious, the mischief usually lasts for three years, and that it is then stopped by the parasitic flies of which we have been speaking, they increasing with the increase of the *Bombyx*, which supplies them with food until they outstrip its progress and in turn almost extirpate it in about that time.

The plans adopted by man to control its numbers are the usual ones of collecting and destroying the insect in its various stages. The stage in which it is most easily dealt with is while in the pupa state, for, preferring to place its cocoon on low twigs, it is easy to supply such a decoy trap, and the twigs can then be brought together and burnt with the pupæ upon them.

A. M.

LONDON TO THE FORE.

THERE are various indications, says the *Saturday Review*, that a change has of late been coming over the spirit of London. For the present, Paris is clearly out of favour, and the throng of travellers and pleasure-seekers is accordingly directed to this side of the Channel. There are whole quarters of London which the invaders seem to have taken by storm. An American will meet almost as many known faces in Bond Street as in Broadway. There were some weeks lately when Americans were arriving in hundreds at a time. And from all parts of our own country the rush to town is more universal than ever. If Dives comes for the season, Lazarus contrives to snatch a few days by a cheap excursion. Everybody who makes money comes to London to spend it. During the season just ending, it was impossible not to be struck by a certain brightness and glow of colour in the western parts of the town; masses of flowers in the windows and balconies, trellis-work with festoons of *Wistaria*, *Clematis*, or *Virginian creeper*; gossamer lace looped up with silken bands of cerise or purple, gay verandahs and striped awnings, and occasionally the line of glistening snow-white houses broken by a red brick wall in the old fashion, picked out with white. Mr. Ayrton's friends the gardeners must be practically reversing the story of the fairy gold that turned to leaves, and qualifying rapidly for residence in the mansions they adorn. At an evening party the exotics will sometimes cost, it is said, several hundred pounds, and the hanging gardens of Belgravia and South Kensington, renewed from week to week, must represent a handsome revenue. We have a notion that not very long ago the display of flowers outside a house was regarded as the height, or rather the depth, of vulgarity, a kind of flaunting, unabashed Cockneyism which wanted only a linnet or canary in a cage to make it complete. The mignonette boxes have given place to fine majolica troughs, overflowing with the most brilliant blossoms. The old English love of colour would seem to be reviving. The red brick houses coming, or returning, into fashion are one sign of it, the rainbow hues of the ladies' dresses another. The *teints dégradés* of Paris have been almost blushed down this summer by the full-bodied, ripe colours of native choice. At the Academy the ladies make the walls look dull. The sea of colours at a fashionable wedding or garden party, or at the morning promenade of the Row towards Ascot time, is dazzling in its chromatic boldness and variety. Altogether out-of-door life is becoming more brilliant and demonstrative. The Marquis of Westminster's experiment with Ebury Square, which is to be converted into a public flower garden, will probably help to bring more colour into the streets. If the experiment is successful, we shall no doubt before long see other oases planted in the weary desert of bricks and mortar. Some day the poor little orange trees in big tubs, which with the other humours of Trafalgar Square—the elaborate squirting of the fountains, and Nelson mast-headed for his victories—afford so much innocent amusement to our foreign guests, may give place to more ambitious horticulture, and a cool umbrageous garden may be substituted for the burning waste of dingy asphalt. Mr. Ayrton might make amends for his exuberance of savage virtue by taking up this idea, and asking Dr. Hooker to carry it out for him; and the reconciliation might be commemorated by a majolica fountain or a piece of sculpture representing the Edile and the Doctor clasped in a fond embrace. One can imagine the scornful incredulity of the Parisians on hearing that the city of fogs and rain, of spleen and suicide, has any pretensions to be considered a city of pleasure, and it may be admitted that London will have plenty to do before in some respects it makes itself as pleasant and attractive to strangers as Paris is. It is naturally out of door life with which visitors are most concerned, and it is difficult to imagine anything more wearisome and exhausting than the perambulation of our streets under present circumstances. Tourists are only creatures of flesh and blood like the rest of us, and the noblest architecture fails to satisfy the cravings of their animal nature. Opportunities for repose and refreshment form a considerable element in their ideas of enjoyment. But the unhappy stranger who has turned his back on Charing Cross or Regent Street; and is on his way westward, soon finds to his dismay that he has got altogether beyond the range of cafés and restaurants. There are, it is true, a few benches on one side of Piccadilly, and of course there are plenty of seats in the Park on which he can rest his weary limbs; but if, in addition to rest, he happens to desire some slight refreshment, a biscuit and glass of wine or cooling draught of seltzer, he is doomed to disappointment and despair. He has no chance of obtaining anything except at the reeking bar of a public-house, in a throng of grooms and stable boys. At some of the park lodges what is supposed to be curds-and-whey and some other remarkable delicacies are on sale; but we should expect to be told that the British Constitution would suddenly tumble to pieces, or that something equally dreadful would happen, if any place were to be established in Hyde Park where an ice or a glass of wine could be obtained on a hot day.

COTTAGE GARDENS IN IRELAND.

BY NOEL HUMPHREYS.

ONE of the many characteristics which a traveller notices on arriving in Ireland by the route of Holyhead and Kingstown, is the comparative absence of flowers in the cottage gardens, and even in those of most of the villas. The gay masses of geraniums, calceolarias, and verbenas which one has left behind at Bangor, and all the pretty sea-coast towns of North Wales, no longer greet the eye in such profusion after crossing the sixty miles of sea that separates us from the coast of Ireland. The windows of Irish cabins, if windows there be, are seldom graced by a flower, not even a solitary fuchsia, nor that old favourite geranium with variegated foliage, which is so seldom absent from an English cottage, however humble.

Of course there are exceptions to these somewhat sweeping remarks; yet, as a rule, it is plainly evident that there is but small love of flowers among the Irish peasantry. How is it that the civilising influence of flower culture has never taken root among the masses of the Irish people? It cannot be that the pure Celtic race has no instinctive taste for inanimate beauty; yet the fact remains, that Ireland is not a land of flower culture. The bit of potato ground is never decorated with so much as a tuft of marigolds, or a rose bush, or a patch of gay *Eschscholtzia*, near to the house; and one never sees the homely everlasting pea, or the starry-flowered jessamine clustering about a cottage door, to say nothing of a China rose, or a sweet scented Clematis, all of which, in their turn, are so universally to be found trained about the entrances of the humblest cottages of our English peasantry. Even the abodes of the wealthy in Ireland often exhibit an absence of floral display of any kind, where in England they may be said never to be absent, as, for instance, about the entrance lodges of country seats, which with us are generally made so gay and attractive with a pretty little flower garden, in which the lodge-keeper takes especial pride, and in which, during all the summer months, mignonette and sweet peas, and the trailing honey-suckle about the trellised porch, greet the visitor on his first entrance with such delightful minglings of the sweetest odours—while about the entrance lodges of the country seats and best suburban villas of the Irish gentry there is, on the contrary, with few exceptions, a total absence of flowers, which gives them an aspect of coldness and desolation that is very discouraging. And yet it is not because flowers and flowering shrubs will not grow—for here, where I am writing, in the coast village of Rosscarberry, in the south-west, I noticed plants of old fuchsias growing to a height of ten or twelve feet, and flowering profusely; and though instances of the culture of ornamental shrubs of any kind, either here or elsewhere, are few and far between, yet they are sufficient to prove that the climate is highly favourable to the growth of flowers and flowering shrubs; as is, indeed, made evident also by those interesting relics of the accomplished Sir Walter Raleigh's love of gardens and flowers, namely, the myrtles which he planted at Youghal after his return from Spain, and which are still flourishing—their ancient trunks having attained dimensions as thick as those of small forest trees.

Encouragement might do much to foster a greater love of flowers; but I have not as yet met with a single announcement of a cottage flower show, with prizes for the most successful cultivator, since I arrived in this country some weeks ago. Absenteeism may have something to do with the absence of the encouragement alluded to—the cultivated classes being so many of them away in London, or on the Continent just at the season of flowers. These arrangements of the London season, which take people from the country just at the time when it is the most beautiful, seem very absurd, but the power of the great blind giant, Routine, seems irresistible; and there is also the ready answer that fashionable life in London would be intolerable at any other time. The French, however, manage matters better; country magnates with their families flock to Paris in November, when the leaves have fallen, and the flowers are faded, and the pleasures of the harvest are over; and they enjoy the gaieties of Paris at a time when they lose comparatively little of the beauties of the country—rushing back, as they do, to the "vie de château" with the first sunny days of April or

May. But to return to the absence of flower-love in Ireland. I may observe that throughout the holdings of the small tenantry of a large estate, not very far to the east of the exquisite scenery of Bantry Bay, I did not find the windows of a single cot or cabin made gay by the presence of a flower; nor in any one of the bits of potato and cabbage ground, with which most of them are surrounded, did I find any instance of the embellishment of the strip of garden with a few flowers. No tiny flower border beneath the window, to send sweetness into the room which serves as "parlour and kitchen and all," and too often as pigstye likewise. Nothing, in short, was attempted in the way of gardening, but the hard, rude struggle to produce cabbages and potatoes sufficient to secure a scanty supply of vegetable food to carry the family, generally a pretty numerous one, through the winter. So far, indeed, their gardening operations are tolerably successful, for the soil is good, and the climate beautiful, but the ornamental—even in the smallest degree—is utterly ignored.

One would think that the beautiful wild flowers which abound in every field and on every rock, and that do not disdain the scanty earth lodged in the crevices of the rude stone walls, would necessarily awaken the dormant instincts which exist in every human organisation for the appreciation and love of the beautiful things of nature. But the awakening does not take place here. The beautiful lesser scabious, that fringes the tops of the rugged walls with azure, makes the barbarous masonry beautiful, in vain. The glories of the orange chrysanthemum that sparkles among the corn, and is well worthy of a place in any garden, the soft turquoise tone of the greater scabious, the bright hues of the purple heather, and the pink, and crimson, and white of the ericas, with the many varieties of hypericum, and the bright yellow masses of the ragwort (which grows so finely in Ireland), none of these appear to attract a passing thought, so all-absorbing is the struggle to obtain a sufficiency of the bare necessities of life, and if by stint and self-denial a little surplus can be realised, the dream is, not of flowers, but of emigration to America. So that flower culture as a national taste has at present but little chance of becoming a characteristic of the Irish people, at all events on this side of the Atlantic.

THE INDOOR GARDEN.

ALLAMANDAS.

THESE beautiful plants, which produce a profusion of yellow flowers, are commonly grown in pots and trained on trellises; but this mode of training them, unless for exhibition, is a very objectionable one. Nothing repays a little care better than the Allamandas, and anyone seeing them grown to perfection as climbers would never think of growing them on low trellises. They will grow freely under almost any circumstances if they receive a little heat to start with and a free supply of water at the root and overhead when growing. The finest plant of *A. grandiflora* I ever saw was grown in a house used in spring for starting plants that had been at rest during the winter. The house had side shelves all round and a broad bed in the centre, with a good depth of cocoa-nut fibre for plunging material heated by hot-water pipes. This bed served also as a propagating pit, and at each end was placed a box about two feet broad and the same in depth; the bottoms of these were covered with four inches or so of brickbats and crocks, and over these a layer of rough turf was placed. In these boxes the Allamandas were planted—at one end was a plant of *A. grandiflora*, and at the other one of *A. Hendersonii*.

Throughout the winter they were kept rather dry, but not absolutely so, and in early spring, when the bottom heat was applied to the beds, they were gradually supplied with a greater amount of moisture. The syringe was freely applied to the breaking wood where it could be done with impunity to the subjects underneath, and after a short time they made rapid and satisfactory progress, breaking equally all over. No stimulants were applied for the first two years after planting until the flowers were set; but in the spring of the third year, the roots becoming rather confined, it was found necessary to top-dress the boxes with good loam and well-rotted manure, which was applied in large rough lumps, and removed in the winter to be renewed again the next spring.

In the summer-time no bottom heat was maintained; but for the sake of Camellias, Azaleas, Oranges, &c., that were grown under their shade for the production of young wood, a little extra heat was

always kept up. It is difficult to imagine the beauty of these plants from May until late in the autumn, for they not only grew vigorously, but as they grew they produced a great profusion of bloom. It required a good deal of work to keep the shoots tied and thinned, for although it is not customary to have to thin out their shoots, here it was quite necessary, for so thickly did they annually overlap each other that leaving them alone would have brought destruction to the blooms. After they had gone to rest they were cut back a good deal, but not completely so, for a little more than was absolutely necessary was left to be cut away in spring, when the fresh start was made, as then it was more certain work. In this condition *A. grandiflora* quite outstripped *A. Hendersonii*, for the latter, being a stronger grower, was not so compact in appearance, nor did it produce such a mass of flowers; yet I never saw a finer specimen of either, nor yet a greater quantity of bloom produced on any one plant than these two plants produced individually. Throughout all their blooming season they were liberally supplied with manure water, which was discontinued some time prior to their being dried off. W. F.

CULTURE OF ACHIMENES.

NEARLY all the varieties of *Achimenes* deserve to be ranked with the most beautiful and useful ornamental plants which our glass houses possess. Their flowers, which are of many delicate and pleasing shades of colour, are produced in great abundance for months in succession, and the plants themselves are by no means difficult to cultivate. While in a growing state they require the assistance of a rather warm and moist atmosphere, but during their flowering season they may be removed to a cooler and drier situation, such as a close greenhouse or conservatory, where they may be said to be indispensable during the summer and autumn months. As all *Achimenes* increase rapidly by means of their scaly tubers, artificial propagation is almost unnecessary, except in nurseries, where it is perfectly understood. I shall, therefore, merely state that cuttings of the young wood, treated in the ordinary way and placed in a brisk bottom heat, will root freely. Taking it for granted that in early spring there is a supply of tubers at hand, they should be separated from the soil in which they have been wintered, and planted in shallow pots or pans (the latter are preferable) well drained, and filled with light sandy soil to within two inches of the top. The tubers should be laid rather thickly and regularly upon the surface, and covered with mould to the depth of an inch, or as much more as the pan will hold. Water should be sparingly applied, only just sufficient should be given to keep the soil in a moist state. If active growth is desired, without loss of time, plunge the pots or pans in a gentle bottom heat. When the plants are about three inches high they should be carefully lifted from the soil and potted in seven-inch pots, placing twelve or more plants in a pot, according to the sized specimens that may be wanted. After potting, place them in a close and rather warm atmosphere till they have become fairly established; a temperature of about 60° at night, allowing it to rise 10° or 15° with sun-heat in the daytime, will be found the most congenial to the plants at this stage of their growth. As soon as they have become established in their pots, air should be freely admitted on all favourable occasions, and the plants kept near the glass. If all goes on well they will soon fill the pots with roots, when a final shift will be necessary. The size of the pots for this shift should be regulated by the size which it is desirable the plants should attain; ten-inch pots will be sufficiently large where moderate-sized specimens only are required; but for very large masses, twelve or thirteen inch pots may be used.

Some first-rate cultivators prefer deep pans for *Achimenes*, but these are better suited for plants to be flowered in a moist warm house, than for those intended to be removed to the greenhouse or conservatory during the flowering season. About twelve plants may be placed in a ten-inch pot. It will be necessary to maintain a moist atmosphere, and keep the house rather close till the plants can lay hold of the soil, and water must be carefully supplied during this time, but the syringe may be used freely if the weather happens to be bright. As soon as the plants start into free growth after potting, air may be more freely admitted, and a slight shade during the forenoon of sunny days will be found beneficial. Varieties of the habit of the old pedunculata should be stopped as soon as they have become established in their flowering pots; and if it is intended to train them in a formal manner all the kinds should be staked before the shoots have become entangled. The stakes should be cut off at the height to which the variety is likely to attain; they should be so arranged as to form the framework of a handsome specimen, and the shoots should be kept carefully tied as they advance in growth. When it is supposed that the pots are filled with roots, an occasional watering with clear manure-water may be given. Indeed, I regularly

water my *Achimenes* with weak manure-water from the time they are well established in their flowering pots till the blooming season is over, and I think the plants are greatly benefited by this treatment. If it is intended to remove the plants to cooler quarters while they are in flower, they should be judiciously and carefully prepared for the change by giving more air, and gradually lowering the night temperature as much as circumstances will allow. When removed they should be placed in the warmest part of the house to which they have been transferred, and guarded from currents of cold air; but if they can be kept in an intermediate house, the flowers will be larger and the blooming season will be prolonged; still, a close kept conservatory will supply a suitable temperature, at least during summer and early autumn.

When they have done flowering, such as are not wanted may be thrown away, merely preserving about two pots of each variety for stock; these should be kept sparingly supplied with water, and if they can be removed to a warm dry house, the ripening of the tubers will be better secured than under other circumstances. Water must be altogether withheld as soon as the leaves assume a sickly appearance, and when the tops die down the pots may be removed to any dry situation, where they will be free from frost, and where they may remain till the tubers are wanted for starting next spring.

For soil, take light sandy turfy loam, peat, leaf-soil, and thoroughly decomposed cow-dung, in about equal proportions, to which add as much sharp sand as will insure a free percolation of water through all of the materials. The loam and peat should be used in a rather rough state; the dung should be broken up and intimately mixed with the sand before it is added to the compost. All the *Achimenes* are very impatient of stagnant moisture at their roots; therefore secure perfect drainage by using plenty of potsherds or lumps of charcoal; indeed, when pots are used, they may be one-third filled with draining materials.—*J. Smith.*

SOIL FOR A WINTER GARDEN.

Nor long since we saw a winter garden of novel construction, the central compartment of which had been planted with much skill. The structure was not large enough to allow of the formation of a winter garden in the natural style, such as we have described in recent numbers, but the grouping of the plants was harmonious, and the vegetation especially was of extraordinary beauty. The secret was evidently in the preparation of the soil. Knowing this, we inquired of the author the means which he had employed, and we desire to call attention to the following reply which we received from him:—"When I am about to plant a winter garden, I first trace out the walks. I then remove the soil from the flower beds to the depth of from 2½ to 3¼ feet, and put in a layer of faggots, rushes, or heath from twenty to twenty-four inches deep, well trodden down. I then fill up with the following compost, on the top of which I put ten or twelve inches deep of soil to compensate for the subsidence which ensues:—One-third good peat soil, one-third leaf-mould, one-third good alluvial soil which has fermented. To the above, I add seventeen pints of dried night-soil to the cubic yard, or the same quantity of manure *de la Mènière*. The peat soil should not be broken up too small, nor should the alluvial soil be sifted. After the planting is finished, I remove the soil from the walks to the same depth, and fill up with coarse vegetable refuse for the purpose of securing good drainage, and in order that those plants which require much nutriment may be able to push their roots in all directions, without starving the young plants and tender subjects near them."—*Illustration Horticole.*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Dracena Fraseri.—This is one of the most striking of fine-leaved stove plants. Many of your readers are doubtless familiar with *D. regina*, which has broad leaves striped with green and white. *D. Fraseri* somewhat resembles *regina*, but instead of the leaves being green and white, they are fiery red and deep copper coloured. As a companion to *D. regina*, no plant could be more suitable or more effective.—*F.*

Trichinium Manglesii.—A neighbour, whom I visited a few days ago, had a lovely little plant of this *Trichinium* growing in a pot in a cool house. He told me that it was rather difficult to grow, and that, although generally treated as a greenhouse plant, in some places it does well out of doors. Its pretty terminal heads of pink flowers, however, make it a useful plant for indoor decoration. Perhaps some of your correspondents may kindly furnish a hint or two as to the best way in which it should be grown.—*W.*

***Primula japonica* Seed.**—Has any one yet succeeded in raising plants from the seeds of this *Primula* offered this spring? and are home-saved seeds of it likely to be so long in vegetating as those imported? or has any one plants from home-saved seeds? Is it not singular that the imported seeds should be so long in vegetating? Most *Primulas* vegetate in a comparatively short time. Is there any structural peculiarity about the seeds of this Japanese variety to hinder its vegetation? Two years is a long time to wait for half crowns growing into beautiful *Primroses*, and then if we are disappointed, it will be time, labour, and money lost.—*D.*

THE FLOWER GARDEN.

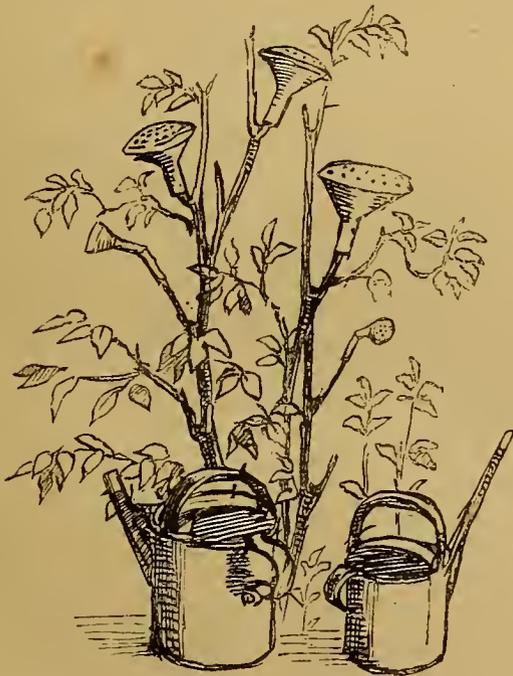

LAMIUM MACULATUM AUREUM.

This is one of the finest of golden-leaved plants for edgings. It does not withstand such full exposure as that which suits the yellow Feverfew, but in sandy or moist soils its peculiar tint is unequalled by that of any other hardy plant in cultivation, and if allowed to flower, its blooms are also very pretty. It does not require to be constantly trimmed like the Feverfew, and when once established it will flourish in the same position for years. In many places it is used for edgings fully a foot in width, and, owing to its deep orange colour and compact habit, nothing could be prettier throughout the winter. It is easily increased by means of cuttings inserted in a cold frame and planted out in March where they are to remain; a matter of some importance, for at that season all the room that can be had is required for plants of a tender character. Some of the other Lamiums form good mixed border plants, as they frequently sport into various variegated forms, notably *L. album*, of which I have had many curious varieties. At Marlow, in Bucks, about eighteen months ago, I found one with very double flowers, which promises to be a great acquisition to our stock of rock plants.

WM. ELLIOTT, *Beechmont, Sydenham.*

NEW ROSE—SOUVENIR DE LA CHALEUR (ROBINSON).

We do not usually attempt to represent flowers, "florist" or otherwise, in our illustrations, from the fact that we cannot reproduce their beautiful colours by means of the printing

press; but the variety alluded to in the following notes is so very distinct in form that we do not hesitate to give it in black and white:—

"CAUNTON MANOR, NEWARK, July 26, 1872.

"DEAR MR. ROBINSON,—Here is a portrait of a rose (on which this torrid weather has no power, and which makes its own rose-water), sent to me by a friend, with the following note.

"Yours truly, "S. REYNOLDS HOLE."

"WARGRAVE HILL, HENLEY-ON-THAMES, July 24, 1872.

"DEAR MR. HOLE,—You will, I know, be interested in a new kind of rose tree, which may now be seen in full bloom in the garden here, between the tool-shed and the pump. The sketch will give you some idea of this magnificent addition to the rose garden. It bears a profusion of bright scarlet blooms, some of which exceed six inches in diameter, while all are symmetrical and firm in character. I believe it was first introduced by those well-known nursery firms the Waterers.—Yours very truly, "HERBERT JEKYL."

THE EVENING PRIMROSES, OR CENOTHERAS.

THESE beautiful flowers are now in full perfection, opening out their large lovely sweet-scented blooms at or about sunset, and lasting, in almost undiminished beauty, till noon the next day. They are almost all of them of easy cultivation, and the humblest cottager can succeed as well with them as the wealthiest millionaire, if he will only try. The gem of the lot is the magnificent and comparatively new *C. marginata*, for the introduction of which we are, I believe, indebted to Mr. Thompson, of Ipswich. I have a large bed of it under my window, which nightly displays some forty immense white blooms, larger than the top of a tumbler, making the whole air sweet with their fragrance. Dotted about in the bed I have plants of *C. taraxacifolia*, also white and *C. macrocarpa*, yellow, with but little smaller flowers; and *C. cæspitosa* and *C. triloba*, with respectively white and yellow flowers, about the size of half-a-crown. These are all low-growing, creeping perennials, as is the smaller-flowered but very gay *C. prostrata*, most useful as an edging plant; and the still smaller but very pretty little *C. pumila*. If you want something a little higher, there is the beautiful annual *C. tetraptera*, with its large pure white flowers; and the perennial *C. speciosa* and *C. fruticosa*, the one with big blooms of snowy whiteness and the other cuffed with gold. Taller still are the biennial *C. biennis*, *odorata*, and *salicifolia*, the two former naturalised as British plants; whilst tallest of all towers up the magnificent *C. Lamarckiana*, its stem thick with blooms often as large as those of *C. marginata*, and only to be beaten, I hear, by the still grander *C. gigantea*, which I have never seen. These last five species are all yellow. Then there is the pretty little annual *C. rosea*, with flowers much resembling those of *Epilobium hirsutum*, and the white flowered *C. acaulis* and *anisoloba*, the former belonging to the *cæspitosa* and the latter to the *speciosa* type, which I shall be glad to receive in the form of cuttings or seed from any kind friend who will send them to me; and the yellow-flowered and rather tender biennial *C. canariensis*, much resembling *C. odorata*. There are other very beautiful and desirable species, about which, perhaps, some one who knows them better than I do will write.

H. HARPER CREWE.

The Rectory, Drayton-Beauchamp, Tring.

OLD-FASHIONED FLOWER GARDENING.

I WISH to arrange my garden in the old-fashioned way, with sweet-smelling and showy flowers that do not require taking up annually. Will you kindly tell me what plants I should require for this purpose? I want a great variety, as my garden is large and particularly effective. There are twelve or more straight borders, varying in width from half a yard, to one yard and a half, besides beds and very wide borders.—Yok.

[For spring flowering, take such plants as *Adonis vernalis*, *Alyssum saxatile*, *Auemone apennina*, *coronaria*, and *silvestris*, *Arabis alba*, *Asperula odorata*, *Aubrietias*, *Bulbocodium vernum*, *Wallflowers*, including *Cheiranthus Marshallii*, various kinds of *Crocus*, *Lily of the Valley*, *Dicentra eximia* and *spectabilis*, *Erica carnea*, *Erysimum ochroleucum*, *Ficaria grandiflora*, *Hepaticas*, different kinds of *Iberis*, *Iris nudicaulis*, *pumila*, and *reticulata*, *Snowdrops*, *Lithospermum prostratum*, *Myosotis dissitiflora* and *sylvatica*, *Orobis vernus*, *Daffodils*, *Phlox reptans* and *subulata*, *Ranunculus monspeliacus*, *montanus*, and the double blossomed *aconitifolius*, *Sweet Rocket*, *Scilla bifolia* and *sibirica*, *Triteleia uniflora*, *Tulips*, and *Violets*. For summer, the following are all good and ornamental, viz., *Acanthus latifolius*, *Achillea Eupatorium*, *Parmica pl.* and *Millefolium rosea*, *Aconitum japonicum* and *variegatum*. *Alstroemeria aurea*, *Anchusa italica*, *Antirrhinum*, *Aquilegia glandulosa*, *cærulea*, and *truncata*, *Aster pyrenæus*, *Baptisia australis*, *Betonica grandiflora*, the double-blossomed *Calystegia pubescens*, *Campanulas* of various kinds, *Catananche cærulea*, *Centranthus ruber*, *Coreopsis lanceolata* and *tenuifolia*, *Corydalis lutea*, different kinds of *Larkspurs*, *Dracopetalum Ruyschianum*, *Dictamnus Fraxinella* and *albus*, *Erigeron speciosus*, *Erodium Manescavi*, *Eryngium amethystinum*, *Funkia Sieboldii*, *Galega officinalis*, *Gentiana asclepiadea*, *Geranium ibericum* and *sanguineum*, *Helianthus rigidus*, numerous species and varieties of the *Flag (Iris)*, *Everlasting Pea*, *Lilies* of various kinds, *Linaria dalmatica*, *Lychnis chalcidonica* and *Viscaria plena*, *Lythrum Salicaria roseum*, *Lavatera unguiculata* and *thuringiaca*, *Lupines* *Malva Alcea* and *moschata*, *Monarda didyma*, *Cenothera fruticosa*, *macrocarpa*, *riparia*, *marginata*, *speciosa*, *Platycodon grandiflorum*, *Phlomis Russelliana*, *Herba-venti*, herbaceous and other *Phloxes*, *Pyrethrum carneum*, *Rudbeckia speciosa*, *Salvia argentea*, *Spiræa Aruncus*, *palmata*, and *venusta*, *Statice latifolia*, and *tatarica*, *Symphandra pendula*, *Symphytum bohemicum*, *Tradescantia virginica* and vars., *Trolliuses*, *Tropæolum polyphyllum*, *Veronicas*, and *Verbascum Chaixii*. Plants for autumn blooming might consist

of *Acis autumnalis*, Hollyhocks, *Aconitum autumnale*, *Anemone japonica* and vars.; *Arundo conspicua*, *Asters*, *Astilbe rivularis*, *Chrysanthemums*, *Eupatorium purpureum*, *Gaura Lindheimeri*, *Merendera Bulbocodium*, *Platycodon autumnale*, *Pyrethrum serotinum*, *Polygonum cuspidatum* and *vaccinifolium*, *Sparaxis pulcherrima*, *Sternbergia lutea*, *Stevia purpurea*, *Tritoma Uvaria*, and others. The following perennial plants have fragrant flowers, viz., *Adenophora liliifolia*, *Allium fragrans* and *odorum*, *Asclepias Cornuti*, *speciosa*, *Douglasi*, *Calamintha glabella*, *Clematis Flammula*, *Crambe cordifolia*, *Crinum capense*, *Daphne Cneorum*, *Pinks*, *Dietamnus Fraxinella*, *Funkia Sieboldii*, several species of *Iris*, *Lavender*, *Leucojum vernum*, different sorts of *Lilies*, *Lupinus polyphyllus*, *Malva moschata*, *Mirabilis Jalapa*, *Muscari moschatum*, *Narcissus major* and *Jouquila*, *Pantracium maritimum*, *Tussilago fragrans*, *Viola odorata*, *Wallflowers*, and, though not a perennial, *Mignonette*. In your narrowest borders such things as *House-leeks*, *Stoncroops*, and *Saxifrages* would do well, and among them might be planted dwarf bulbous plants, such as *Crocuses* and *Squills*.]

FOLIAGE v. FLOWERING PLANTS.

THE recent heavy rains and the almost total absence of sunshine have seriously marred the beauty of all flower gardens in this district; and especially is this the case where dependence has been placed on flowering plants alone for display. In spite of wind and storm, however, the masses of dwarf foliage plants stand out bright and distinct, apparently none the worse, beyond a little exuberance of growth, for the drenchings they have received. In our changeable climate the employment of fine-leaved plants might, I think, be extended with advantage; for where anything like permanent effect is desired, it can be secured more easily by masses of foliage than by depending altogether upon flowering plants. I have never seen such foliage plants as *Colens Verschaffelti*, and its variety *marmorata*, *Iresine Lindeni*, *Golden Feather*, *Abutilon Thompsoni*, &c., do better than they have done this season. Of course, it is easy to make a garden too sombre-looking by using too much dark foliage; but plenty of lighter tints are to be found among *Centaureas*, *Cerastiums*, *Guaphaliums*, *Lamiums*, *Euonymus*, *Santolina incana*, *Stachys lanata*, *Dactylis glomerata variegata*, and the almost endless varieties of variegated *Geraniums*, not forgetting the large family of *Succulents*, and the beautiful *Maple*, *Acer Negundo variegatum*, and several beautiful *Ivies*, *Vincas*, *Yuccas*, &c. There is one description of flowering plants that has passed through this season's watery ordeal unscathed, and that is the *Viola cornuta* and *Imperial Blue*. Amongst *Verbenas*, the old hardy *venosa* is undamaged, and amongst scarlet bedding *Geraniums* *Tom Thumb* in a season like the present is still a "General." Amongst annuals for bedding I may mention *Balsams* as worthy of more frequent planting, both as masses in the centres of large beds, and as single plants in prominent positions. When planted out in good soil they are not like the puny things often seen in pots, but frequently attain a height of three or more feet, and nearly as much in diameter. Where cut flowers are in demand, double *Zinnias*, of various shades of colour, are exceedingly beautiful, and will last a considerable time, and do not drop their petals like many other flowers.

E. HOBDAY.

Whence come the Finest Roses?—I cannot at all agree with the Rev. Mr. Reynolds Hole that "as a rule the roses from the briar are the best." Those shown by that veteran rose-grower Mr. Keynes, at Hereford, this year were all grown on the *Manetti*, and yet they won for him all the first prizes in the leading classes, and that too against such distinguished growers as Mr. George Paul, Mr. Cant, and Mr. Cranston; surely, that says a great deal in favour of the *Manetti*; but there are still many other reasons why I like the *Manetti* as a stock: in the first place, a rose worked on the *Manetti* will give three times as much bloom as it would if worked on a briar; again, a bed of roses on the *Manetti* has surely a much prettier effect than a bed of roses on the briar; and, as a last recommendation and certainly not the least, the *Manetti* will thrive and do well on any soil, whilst the briar unless planted in a very deep rich loam, is of little or no use. With regard to the maiden blooms from the briar, I believe that they are better than the maiden blooms from the *Manetti*, but I think that the second year's bloom from the *Manetti* will beat them all. I hope some other rose-growers will kindly give us the benefit of their experience in this matter.—ROBT. N. G. BAKER, *Heavitree*.

Double Scabious.—A few years ago some very handsome and very double forms of *Scabiosa nana flore-pleno* originated with one of our leading German seedsmen, or at least were distributed by him. As decorative plants for the garden they were great improvements on the tall-growing *Scabiosa atropurpurea*, so well known in our

borders, and wherever their cultivation has been taken in hand they have to a great extent superseded the older type. I saw a collection of seven varieties of *Scabiosa nana* in flower last summer, and made a note of the different colours at the time, because so attractive. The palest was a lilac-coloured flower; then came a pale pink, each floret having a thin edging of white; next an orange-red, very showy; then a bright crimson, then a deep claret-coloured flower, and then a shaded purplish maroon. Such were the ascending shades or hues of colour, from the palest up to the darkest. All the varieties to which I have just alluded had a branching, bush-like habit of growth, each plant bearing many flowers. Apart from their undoubted value as decorative plants in the garden, they well deserve cultivation in places where large quantities of cut flowers are required during the summer months. Each plant supplies a good number of ranuncululike flowers, that last a considerable time after being cut, and are therefore more durable than many other flowers grown for this purpose. They can be planted in the herbaceous border, or on any convenient spot; they do not require any special mode of cultivation, though the more generous the soil in which they are planted, the finer will be their flowers. Collections of seed of these dwarf varieties of the *Scabious*, saved in colours, are easily obtainable.

Moræa iridioides.—This lovely and distinct-looking plant has proved quite hardy at Glasnevin, where it is now in bloom, as it has been throughout the summer. It used to be grown in pots in the houses but, placed out in a peat border in front of them, it has thriven apace, attaining a height of about three feet. The rich yellow flower is iris-like, but with the parts disposed in nearly one plane and with rich black spots towards the centre. It never bloomed when grown in pots. We recommend the plant to every lover of hardy subjects. It is suited for association with the finer *Iris*es and *Lilies*, or for placing here and there in beds of choice American or other shrubs.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Virginia Creeper.—Can any of your correspondents tell me from experience the age to which this creeper is likely to attain?—CALVICERS.

Clerodendron foetidum.—This is a perfectly hardy herbaceous plant in my garden, and is now opening its showy blossoms on my warm border. It thrives best in rich deep soil, well drained.—D. F. R.

Saxifraga ciliata.—I find this the handsomest in foliage of the large-leaved *Saxifrages*. It is, however, rather tender, and requires a warm sheltered position and rich light soil.—F. F., *North Devon*.

Helleborus argutifolius.—This is one of the most effective foliageed plants, and, moreover, quite distinct in aspect from anything we have. It, however, requires a warm and sheltered position to do well.—CLIFTON.

Anomatheca cruenta.—The flowers of this little bulb now swarm and sparkle everywhere in my mixed border (mostly composed of peat and leaf mould), and are much admired by every visitor to my garden.—S. WEXFORD.

Yucca stricta.—This fine and bold habited species is now in vigorous health in the Dublin Botanic Garden, where it has proved quite hardy during a trial of ten years' duration.

Richardia maculata.—This we do not remember to have seen used in the flower gardens about London. It forms the centre of a bed at Glasnevin, and looks very attractive. The habit is bold and novel, the marking of the foliage pleasing, and there it makes a free growth in the open air.

Malva mauritanica.—Permit me to call the attention of lovers of ornamental perennials to the merits of this fine kind. With me it forms a mass of clear rose-coloured flowers four to five feet high, and is a noble ornament of the mixed border in autumn.—J. S. W.

Variegated New Zealand Flax.—This, in good specimens, is perhaps the most striking flower-garden ornament recently introduced. No doubt in the southern and milder districts it will, like the green kind, prove hardy, but it will be even more useful where it must be kept indoors in winter. Housed in the conservatory at that season, it will prove one of its highest ornaments.

Cerithe minor.—This is a singular plant, belonging to the order *Boraginaceae*. Its height is scarcely two feet, its growth is curved and branching, the flower-stems arching over considerably, so much so that the delicate yellow tube-shaped bloom is entirely hidden at the apex of the stem by the long and closely-inbricated pale green leaves with which the stem is furnished. I should like to see it grown in a suspended basket, when one might see its flowers, while its foliage would contrast with that of many other plants.—W. T.

Rudbeckia californica.—I am glad to see that this vigorous herbaceous perennial is beginning to occupy a place in good collections. It is the best, so far as I have seen, of the yellow-flowered species of *Rudbeckia*, its large golden yellow flowers, many of which are about five inches across, being produced in abundance, and it has a conspicuous brownish conical disk two inches or more in length, which adds to their interest. This plant should have a place in all large mixed borders; it would also form a capital subject for planting in shrubberies.—S.

Platycodon (Campanula) grandiflorum.—This fine herbaceous perennial is flowering freely in several establishments this season, and owing to the beauty of its large cup-shaped deep blue flowers, and the freedom with which they are produced, I wonder that it is not more planted than it is, as it generally thrives in sandy loam, and is a conspicuous border plant. I have also noticed the following varieties of it, viz.: single and double white, double blue, and a light blue double and single, all of which are equally worthy of culture. At the Wellington Road nurseries there is a form which seemed quite distinct in habit from the common kind: it has a somewhat trailing habit, whereas the common kind has an erect habit. This latter variety struck me as likely to be a good subject for hanging over rocks, &c., but for the flower border it is not at all equal to the common form.—T. S.

THE ARBORETUM.

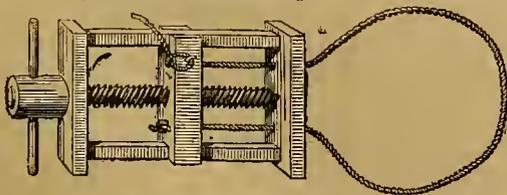

A HANDY MODE OF TRANSPLANTING.

THERE is a very good method for the transplantation of small trees, specimen conifers, evergreens, and like subjects, sometimes employed on the Continent, which deserves to be better known with us. Round each tree a circular trench is opened large enough for a man to move about in it at his ease. The depth should be equal to that of the deepest large roots, and a ball of earth large enough to insure the safe removal of the tree should be left. All the smaller roots found in the trench should be carefully preserved. The ball is shaped into the form of a truncated cone, with its smallest portion below. It is next surrounded with light deal boards, separated from each other by the distance of three-quarters of an inch or so, like the staves of

Small Machine for Lifting Specimen Shrubs and Conifers.

a barrel. They are next secured temporarily by a suitable rope. A man then descends into the hole and fixes the rope by means of the screw apparatus shown in our figure, so as to press the planks firmly against the soil of the ball. The press is then removed and the same thing done higher up, within say four inches of the top, an ordinary cask hoop being first nailed round the planks before the screw is unfixed. The ball being firmly fixed in its proper position, it is hove over so as to get to its underneath part. The bottom of a cask

Screw used in preparing specimens for removal.

having its boards fastened together with a circular piece of sheet iron rather larger than itself is passed under, the iron being pierced with two or three holes and turned up so that it may be nailed against the planks. In some cases the stem of the tree should be fixed by iron wire to the sides of the improvised cask. When it reaches its destination it is gently inclined to one side and the bottom boards

removed. The hoops are next unfastened, the boards removed, and the roots carefully arranged in their natural position.

The apparatus costs a mere trifle, as will be seen from the following estimate. A press made of oak and beech, with the rope included, only costs about eighteen shillings; if it were made of iron it would possibly cost less. For a ball six or seven feet in circumference and eighteen to twenty inches high, the boards, hoops, cask bottom, sheet of iron, and nails would cost less than a couple of shillings. If still greater economy is desirable, what are known as Yankee flour barrels may be used, if they are cut in two and taken to pieces. With these simple appliances two men can prepare five trees a day ready for hoisting on to the cart or other conveyance intended to receive them.

MARKS ON TREES.

MARKS cut on trees are permanent if cut into the wood; if only into the bark they become gradually obliterated. Incisions made in the true woody substance become filled up with the new wood that is formed in annual layers, and are never more seen unless the wood be longitudinally severed so as to expose them again. My grandfather had given to him many years ago a bit of oak with a Roman I, and some other letter with a perpendicular stroke—possibly an R—but partly destroyed by a chop of an axe. It has the following note pasted on the back:—"This piece of wood was found in an oak tree fifteen inches below the bark, and contained the initials of King John, who died at Newark 600 years ago." This may be one of the identical "brands" mentioned in the guide books.—J. T. F., *Hatfield Hall, Durham.*

The following quotation from the late Mr. J. R. Walbran's "Guide to Redcar" is interesting in connection with this subject. The author is speaking of Kirkleatham:—"There is, too [in the museum], a portion of a tree grown in Newbrough Park, near Thirsk, and sent here by Lord Fanconberg, which, on being cut down and split up for billet-wood, was found to bear the following inscription, graven in rude Roman capitals about five or six inches high, on a bole or core of about twelve inches in diameter, which came out entire from an outer rind of about four inches in thickness:—

' This tre lovng time witnes beare
Of tow Lovres that did walk here. ' "

The letters encircle the tree in nine spiral lines, occupying a space of about five feet, and are impressed both on the bole in which they have been "originally committed, and on the rind by which they have been subsequently enveloped. Two hearts, each transfixed with an arrow, after the usual and approved fashion, are introduced in the third line, and in one of them may be traced the letter B. The other is uninscribed."—*Edward Peacock, in "Notes and Queries."*

TAPERING TREES.

ESSENTIAL as are the trees that drop their shoots toward earth to the planter who wishes to realize to the full the beauty of the tree flora of our gardens, they are scarcely so much so as those of which every branchlet points skyward—those of the tapering tree, from the stately Lombardy poplar to the slim Irish juniper. We have round towers as well as fountains of verdant life; the leaf-builders raise spires as well as castles. There is no tree yet discovered more effective in the landscape than the Lombardy poplar towering above our numerous round-headed trees. This is what may be considered the queen of our pointed trees; it is as familiar to all as any tree can be, and abundantly planted. But there are other tapering trees to which we wish now to advert.

One of the trees next in value to the Lombardy poplar is the pyramidal acacia. Everybody knows the common Robinia or acacia—which, if it never answered the expectations which Mr. Cobbett placed in it, is nevertheless a welcome ornament in our pleasure grounds, and is one of the best of all trees for garden or street planting in cities, as it retains its verdure for months after the common lime has become as rusty as an old carpet bag. Every form of this tree has indeed, "the verdure of ten meadows in its gracefully cut leaves." The pointed form of such a tree must be valuable, and this is one that is easily procured, and should be planted everywhere. It grows as compactly and is as distinctly tapering as the Lombardy poplar, and has all the charms of the species as regards verdure. Good specimens may be seen on the borders near the west end of the flower-walk in Kensington Gardens, where, however, they are half hidden among other trees, and no doubt often escape notice from the passer-by. It is almost useless to plant such trees, or any trees, where, from being crowded up with other subjects or badly placed, their peculiar character is half obscured. Not growing so tall as the Lombardy poplar, or not so vigorously, this should be associated chiefly with medium-sized trees and vigorous shrubs. It is also a capital plan when dealing

with a subject of any character like this, instead of putting it in the centre of a group of low trees or as the centre to a company of vigorous shrubs, to boldly place it on the very margin of the mass. For isolation such subjects are peculiarly suitable.

A lovely tapering tree is the cypress (*Cupressus sempervirens*), as all know who have observed it in mild districts where it is much planted. We have noticed it thrive most commonly in districts under the influence of the sea, but the best specimens we have ever seen are at White Knights, near Reading, in the part of that place now belonging to Mr. Waterhouse, the father of the well-known architect. And a fine, old, healthy upright cypress is one of the most charming trees to be seen in this world. The fact that it grows with us into such specimens as those at Reading proves that it is not only those who live round the basin of the Mediterranean, or in sunny Italy, that may enjoy it in their gardens.

Lawson's erect cypress (*C. Lawsoniana erecta viridis*) is likely to form one of the most valuable of all tapering trees. The normal form of Lawson's cypress, found wild in Northern California and Oregon, is naturally one of the most graceful of all trees, attaining a height of a hundred feet in its native wilds, and quite hardy everywhere in these islands. The erect variety is to the normal form what the Florence Court yew is to the common yew. It is very erect and dense in habit, and of a light rich vivid green, not glaucous like the species. There are other erect forms of the same species, but none of them have the peculiar and very desirable green hue of this, although in other respects they are very desirable. From its thorough hardiness, this tree may be used in districts where the upright cypress would perish from cold; in fact it is likely to be everywhere useful. As the species to which it belongs naturally attains a great height, it may be expected to form a stately tree. This should be borne in mind in planting it, as it will doubtless prove effective in many positions in which the medium and smaller sized tapering tree would not be suitable.

The red or Virginian Cedar (*Juniperus virginiana*).—Sometimes in our rich and well-sheltered pleasure grounds the Virginian cedar resembles common spiral or fir-headed trees; but almost everywhere one sees it in the Eastern States it is as decidedly tapering as the upright cypress, as anyone may tell who has travelled by rail from New York to Philadelphia. Along many parts of the line the red cedar is common—a close, tapering, low green tree, with from four to ten feet of the base of the stem quite bare and weather-beaten. On the mountains near Newburgh, on the Hudson river, the wild specimens and groups of this species seeded in the distance upright cypresses planted by man, so effective did they appear in the landscape, and so diverse were they in aspect from any tree common in natural woods. The red cedar grows over a vast area, inhabiting some of the coldest as well as the warmest regions, and is quite hardy in this country. Considering this and its peculiar habit, the tree is a neglected one, and far more worthy of the attention of planters than many of the half-hardy kinds sold at high rates.

The Irish Yew (*Taxus baccata fastigiata*).—This beautiful variety of the common yew is so well known and so frequently planted that it need only be mentioned here. It is very likely that we shall soon have a variety of variegated forms of the same type, as, apart from varieties already announced and sent out, others of a decidedly tapering form have sprung up in several different nurseries.

The pyramidal variety of the common London plane should prove attractive to every planter, and particularly to every city planter, as, where there would not be room for the great arms of the common plane to spread forth, this might find a place. We have, however, not seen specimens of it sufficiently developed to say anything of its character as a tapering tree; but young specimens promise well. There can be no doubt, however, as to its deserving a place in the front rank of our noblest trees.

There is a tapering form of the common oak (*Quercus pedunculata fastigiata*) which deserves attention from the planter, not only from its interest as a very remarkable variety of the British oak, but also from its distinct and picturesque port. The best specimens I have seen were in central France; but doubtless there are many good ones in various parts of England. It is to be regretted, however, that trees of this character so rarely show themselves in our pleasure grounds, as this proves that they are either not planted at all, or so badly placed that they are either unnoticed or hidden. *Q. fastigiata viridis* is another variety of oak with a tapering habit, also well worthy a of place in our collections.

Betula fastigiata must be classed among tapering trees, and judging from small examples of it seen in Messrs. Osborn's nursery, it promises to be very ornamental. It was received quite accidentally along with some other plants from Germany. Amongst the varieties of the common hawthorn may be found a good type of a pyramidal tree in the form of *Cratægus oxyacantha* called *stricta*. This differs but little from the common May in anything but habit, which is erect and tapering, its branches being almost perpendicular. Q.

Varieties of *Cytisus purpureus*.—M. Louis Leroy, of Angers, has lately sent us some flowering branches of three varieties of *Cytisus*, which, notwithstanding their beauty, are seldom met with in gardens, and are little known even to many horticulturalists. They are:—*Cytisus p. elongatus*, which has very long pendent branches and broad, handsome, purplish-violet flowers; leaves small and smooth; it is much more vigorous than the type;—*C. p. albo-purpureus*, allied to the white variety, but having the flowers dashed with violet; the tree is not so vigorous, and has slender branches and smooth small leaves;—*C. p. incarnatus* major, leaves small and downy; flowers large, long stalked, in long branching clusters; standard and petals violet-rose and violet; a handsome plant. These three varieties are multiplied, like the type (*C. purpureus*) by grafting on *C. Laburnum*. We would suggest that they should be grafted not only on tall standards and half standards, as is usually done, but also on dwarf stocks, when they would form excellent subjects for covering rockwork with their long, elegant, and flower-laden branches.—*Illustration Horticole*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Quercus glabra.—This noble evergreen oak has this year made shoots one foot long in my garden at Queenstown, where it promises to become one of our handsomest evergreens.—G., *Queenstown*.

Viburnum macrocephalum.—This noble flowering shrub has been in flower against the sunny wall of my greenhouse since April, and is even yet opening a few of its large masses of blossoms.—F. LEWIS.

Cytisus nubigenis.—Let me recommend this to all who desire to add to their collections of flowering shrubs. Its flowers are whitish pink, and it is agreeably distinguished by a fine odour.—M.

Magnolia Campbellii.—This new and very remarkable ornamental tree is, we are informed by Mr. Gumbleton, thriving so well and growing so rapidly in Mr. Crawford's garden at Cork, that it may soon be expected to flower there.

Abutilon vitifolium.—I am surprised this really noble shrub is not better known. With me, its large delicate marve-coloured flowers are now about to open, and it will for many weeks remain one of the most striking objects in a large collection of flowering shrubs. It thrives both as a wall plant and a shrub. My garden is near the sea-shore, but sheltered.—ARBOR.

Desfontainea spinosa.—My bush of this is now the object of much admiration—a holly-like bush, with gloriously brilliant short tubular blossoms. One wishes it would thrive everywhere in the open air, but is it not better worthy of pot-culture than many things we highly esteem for the greenhouse? Will any of your readers say in what positions they find it thrive best—shady or sunny?—H., *Exmouth*.

Curiously-shaped Elder Tree.—In Canonbury Laue, Islington, is an elder of a very unusual form. As nearly as I can estimate, from a glance while passing it in a cab, the stem is about twenty feet high, at which elevation its first branches appear, and then spread horizontally and dependently. The result is a tree with a globular head of some ten feet in diameter, the total height of the tree being about twenty-five feet.—W. T.

MEAN TEMPERATURE OF EVERY DAY IN THE YEAR 1871.

From Mr. Glaisher's *Reduction of the Meteorological Observations*, published as a Supplement to Vol. II of the *Journal of the Royal Horticultural Society of London*, new series.

PROFESSOR OWEN'S GARDEN, SHEEN LODGE,
RICHMOND PARK.

The most attractive gardens are by no means the largest. Indeed, the most beautiful in England are comparatively small ones. Professor Owen's garden is one of the simplest and most unpretending, but withal one of the most charming in the neighbourhood of London. Many a visitor to Richmond Park enjoys the look of his cottage, as it nestles on the margin of the noble sweep of undulating ground near the Sheen Gate, but it is from the other or the garden side that the picture is most beautiful. A lawn, unbroken by geometrical twirlings, stretches from near the windows to the boundary, and it is fringed with numerous hardy trees. Here and there are masses of flowering shrubs, and an odd bed of lilies, while numerous herbaceous plants peep from among the roses and rhododendrons. Quite near the house stands a noble specimen of *Gleditsia triacanthos*, graceful in foliage as any inhabitant of the fernery, yet stately

old specimens of the weeping beech, which displays such an uncontrolled variety of picturesque branching.

There is in the main part of the garden only one walk, and this takes one round the whole place, and does not needlessly intrude itself, as it glides behind the outside of the groups which fringe the sweet little lawn. Instead of this walk coming quite close to the house it is cut off from it by a deep border of rhododendrons, intermingled with lilies and the finer herbaceous plants. These, in consequence, look into the windows. Instead of looking out, as usual, on a bare gravel walk, the eye is arrested by rhododendrons or *Spiræas*, with here and there a lily, a foxglove, or a tall evening primrose, according to the season. Beyond these, at a distance of twelve feet or so, is a broad, convenient walk; the effect of the border from the other side of the garden is quite charming, inasmuch as it makes the already beautiful creeper-covered cottage seem to spring out of a bank of flowers. Therefore, I think that the

Gleditsia, in Professor Owen's Garden.

and picturesque in the highest sense. Of this Professor Owen writes, in reply to a query of mine respecting this tree:—

“It was planted by my predecessor, about 1812; its present height is between seventy and eighty feet; it has lost two large boughs by gales, when in full sail of foliage, with a wet sheet (*i.e.*, with rain accompanying the storm), in the last ten years, and I have had a chain put round the three remaining chief divisions, which tower aloft from the main trunk, by way of precaution. But the best days of the tree have passed. I supply a botanical friend during his lectures at one of our medical schools, with the branched thorns from the trunk, especially when any exhibit the metamorphosis into the ‘leaf.’ The specimen at Kew exhibits the decrepitude of age; that at Fulham, in the bishop's garden, if it still lives, is an older specimen. Few deciduous trees, if any, are more ornamental in their prime.”

And so would our readers say if they saw it in full beauty, its long lower arms stretching far out near the turf, laden with their fern-like leaves, and the whole surface of the tree, for eighty feet upwards, broken up in the boldest and most picturesque manner. In fact we know of no tree, except perhaps

placing of a wide border, richly embellished with evergreens, near the house, is a variation from the ordinary mode of laying out villa and cottage gardens which it would be desirable to adopt occasionally. Another agreeable feature of Professor Owen's garden is the grass walks, which ramble through a thick and shady plantation. Even in our coolest summers there is many a day on which such shady, cool walks, with a carpet of grass, are the most enjoyable retreats one can find. Besides, their margins form a capital situation for naturalising many beautiful hardy plants, which are seen to great advantage in such positions, as, for example, daffodils, hardy ferns, scillas, the forget-me-not tribe, the harebells, and numerous other plants.

W. R.

Prussian Gardens.—In visiting these, nothing strikes an Englishman so much as the want of evergreens; the winter is too severe for anything except a few conifers. It is astonishing, too, the amount of labour that is expended in keeping the turf fresh and green. What would they not give for an English lawn? Many Prussian gardens are thrown open two days a week in summer on payment of sixpence, the money thus obtained being divided among the poor in winter.—*Viator*.

ART *v.* NATURE.

BY NOEL HUMPHREYS.

THE following is a true and verbatim report of a case recently brought before a high court of Taste. Art, through the agency of the topiarist, was at issue with Dame Nature, the defendant in this case. Two leading pleaders, Cutbush and Freegrove, were engaged, at enormous fees, on either side, as a very serious and artistic horticultural question was at issue. The defendant, a certain Dame Nature, had insisted that a certain bear, and a certain hunter, and a certain dog, the work of a certain disciple of Art, by name Topiarius, should be allowed to sprout freely into the form of a wild Yew tree, as she, Dame Nature, the defendant, had originally intended; Topiarius, claiming that such liberty would be an infringement of his vested rights.

The eloquent and rapidly rising counsel, Shearington Cutbush, Q.C.,* opened the case with his usual eloquence and skill, at once taking the bull by the horns, or rather the bear by the paw, which he shook in very friendly fashion, declaring that he would stand by him, and trusted that the gentlemen of the jury, after they had listened to what he had to say, would do the same, and give an unanimous verdict in favour of his client.

He said that a faction had arisen under the *wild* auspices (hear, hear) of Dame Nature, a very respectable, and very influential, and very important personage, against whose general character he had not one word to say (hear, hear). But there was a power, which, in the interests of civilization and progress, he, Cutbush, considered co-equal and co-important with that of Dame Nature—he alluded to that all-accomplished personage, Art, the plaintiff in this case. Dame Nature, he said, was all very well in her way (oh, oh, from the defendant's supporters). He did not wish for a moment to depreciate the character of defendant (hear, hear); she was a highly necessary adjunct (oh); but when she assumed the power of dictating tyrannically to his client (hear, hear, from the plaintiff)—when she insisted that provinces which had been legitimately conquered by the refinements and accomplishments of the plaintiff, Art, should relapse into the wild domain of Dame Nature (hear, hear)—then he took his stand on the grounds of justice and progress, and insisted that the high court of Taste and Art should interfere, in order to protect that same cause of progress and civilization (hear, hear, from plaintiff's supporters) from a wild overgrowth (hear, hear, from the same part of the court) of Nature's many-branching legions, who are ever on the watch to disfigure the endeavours of his client, Art, to evolve beauty and symmetry and regularity (hear, hear) from formlessness (hear) and irregularity. He would make bold to say that, where Nature had produced only a wilderness, his client, Art, had stepped in and made—(cries of "a bear garden, a bear garden")—he must call upon the court for protection—that, at least, need not become a bear garden—(hear, hear, from plaintiff's party, and silence, silence! from the clerk of the court). Bowing to the Judge, Mr. Councillor Cutbush proceeded. "In a place," he said, "where adverse opinions were professed by a small but noisy faction, it might be better for him to confine himself to generalities and avoid details, with which view he would appeal to the honest convictions of anyone present, whether, if a human being, wandering in the tangled fastnesses of a wild forest, came suddenly upon a part which was cropped trimly into shape, and where the rank grass was mown down to a velvet surface, the wanderer would not build his dwelling there, in preference to erecting it in the depths of the uncultured wild? (hear, hear). He thanked his friends for that cheer, they acknowledged thereby the truth of a great principle—the fanatical advocates for mere nature were not aware of the depth of the wild chasm into which they were plunging. They might as well prefer the rude mass of the Pentelic rock to the masterpieces wrought from it by the gifted hands of Phidias—of Scopas—of Lysippus (hear, hear). They might as well prefer the rough lump of ochre, or of chalk, to the works which a Raphael or a Rubens had produced by their means (hear, hear). In short, they might as well prefer the wild incongruities of chaos to the exquisite orderings and the

regular and beautiful results produced by the inspired supervision of artistic genius. And he therefore called upon the jury to give him a verdict in favour of the preservation of those interesting works of art which it was sought by the defendant and her supporters ruthlessly to destroy." The learned counsel sat down in the midst of reiterated cheers; and cries of "Long live the disciple of art! long live Topiarius!" resounded through the court, till silenced by command of the impartial judge.

When the turmoil and uproar caused by the eloquent pleading for the plaintiff had partially subsided, Brother Freegrove stood up, in no way daunted by the eloquent and ingenious oration to which he had listened with as much admiration as the supporters of his opponent had done. He smiled at the judge—to gain time—and hitched up his black silk gown, to gain a little more. He then rustled his brief into shape for perusal, and, silence being at length re-established, he commenced his defence as follows:—

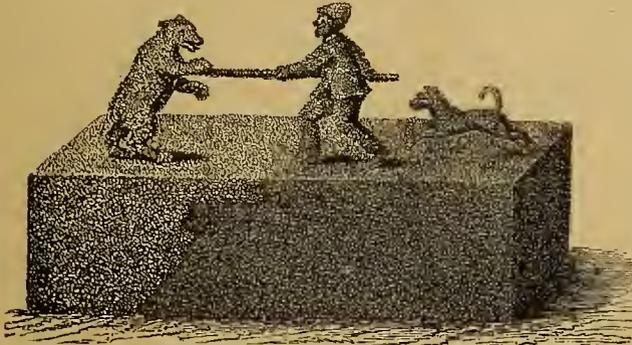

"My lord, and gentlemen of the jury,—I believe I shall be able to prove to you that, however eloquent my learned Brother Cutbush may have proved himself on the present occasion, he has not been strictly logical, either in his premises or in his deductions (oh! oh! from plaintiff's supporters). He would, however, endeavour to follow him in the flood of eloquence which he had poured out before them. His learned friend had admitted that the defendant in this case was a very important personage. He thanked Brother Cutbush for that frank admission, and he would add that, in his opinion, and he hoped to have the court and the jury with him, the defendant was a personage that must not be trifled with (oh! oh!), especially in the manner in which the pretended disciple of Art, Topiarius, who was the real plaintiff in this case, had trifled with her. Art, he would observe, who was, as stated by his opponent, a most respectable and accomplished individual, was merely the ostensible plaintiff, placed in that position for reasons which must be obvious to all present. Art had many (so called) disciples, whose vocation was, however, mechanical rather than artistic. That of Topiarius, for instance, who did for the vegetable domains what his co-disciple Tonsor did for the animal world. Tonsor cut off the beards of men and made them look as much like women as it was possible to make the ruder beauty of men approach the more exquisite perfection which that quality attains to in women." (Great rustling of silks and satins in that part of the court in which the ladies were accommodated with seats.)

Brother Freegrove paused—he saw that he had created a favourable impression in the quarter towards which his last shaft had been directed. He hitched his gown higher on the shoulder, and continued—"Tonsor—the indefatigable Tonsor—armed with his ever-active razor, would have gone into the 'wild and tangled' forest, as his brother had termed it, and have shaved off the *wild* tawny mane of the forest lord, if he had ever mustered the pluck to come up to the scratch—which he luckily had not" (laughter and cries of shame, order, silence). After a brief contending uproar of applause and disapproval, Brother Freegrove proceeded. "Now Topiarius had ventured, he must admit, farther than Tonsor—his brother shaver—for he had actually cropped and sheared, if not a lion, at all events a bear—the very bear in question—which was, however, a bear which it was very safe to crop (shame, hear, go on), for as all knew full well, it was not a natural bear, though yet a living bear (hear, order). When he said it was an unnatural bear, he did not mean to say that it was a blue bear, such as they had often seen swinging over the door of an ancient hostelry, nor yet a red bear, nor a golden bear; but none could deny that it was a *green bear*" (hear, hear! order), and therefore a sham bear.

"Its creation was altogether an unnatural act on the part of Topiarius—a cruel act—he had hunted him up with his shears till he had fairly 'tree'd him' (laughter), which in bear hunting was considered equivalent to destroying him—the tree'd bear was, proverbially, 'a gone coon' (order, order)—well, he would say no more upon that point, if it was so painful to the feelings of Topiarius, the real plaintiff in this case, but rather confine his remarks to Topiarius himself, who had not only falsified the bear tribe, but had 'played the very bear' with the noble yew by the action of his cruel shears (order,

* Q.C., in the department of the ancient court in which Cutbush practises is said by antiquarians to be the initials of Queer Cutter.

order). He would, therefore, call upon the jury to return a verdict for Dame Nature, the defendant, and also for the maltreated yew tree, which had been tortured from its natural form, like the Chinawoman's foot strapped into the unyielding wooden slipper (hear, hear! no, no! yes, yes! order, order). In conclusion he must beg leave to notice his learned friend's illogical use of Pentelic marble and the chisels of Phidias and Co. There was not the slightest analogy between them and the topiarian disfigurer of the yew tree. The Pentelic rock lay inert and incapable of any further development of its own, and so did the chalk and ochre, all three of which were legitimate materials for the creative genius of man to work upon; but the yew tree had a development of its own to perfect. Its dark majesty in its own grand and peculiar forms of development was one of the glories and wonders of

Example of Yew-clipping. (After P. Launberg, 1654.)

the woods. To curtail the welcome shade which its great far-reaching arms were destined to afford was at once a horticultural crime and an æsthetic blunder, which should be justly punished by the high court of Taste and Horticulture."

Brother Freegrove sat down amidst a storm such as has seldom been heard in a Court of Taste; but the verdict was for Dame Nature, and for the restoration of its invaded liberty to the noble yew, which had been so cruelly "cribbed, cabined, and confined" by Topiarins, under the false pretence of his being a true disciple of Art, in whose august name the action was ostensibly brought.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 124.)

PREPARATION OF THE SEED FOR SOWING.

UNDER this heading we intend to speak of those means which are employed to excite vitality in the seeds before sowing them, and by which a speedy germination is secured after they are sown, and also to preserve vitality in seeds until they are sown. They may be put in practice either immediately before sowing the seeds, or they may be continued until the natural time of germination. Simple means are, according to our experience, the best in this matter, and the more so the nearer they approach the course of nature. These means are soaking and layering.

SOAKING AND LAYERING.

In soaking, the seeds are steeped for twenty-four hours in lukewarm soft water which does not contain any mineral substance in solution, and then sown. If this operation, when practised with fast-germinating seeds, causes them to sprout, they should, after the lapse of twenty-four hours, be subjected to the free influence of the air. If the quantity of seeds is small, the water should be poured off at the end of the twenty-four hours, and the seeds should be allowed to stand in cups or saucers in a warm room, with only just so much lukewarm water in the bottoms of the vessels as will maintain an equable condition of moisture without covering any of the seeds completely. The cup should also be covered with paper, so as to keep up a moist atmosphere in the inside. Fresh water should be poured in from time to time, when necessary, so as to keep

the bottom of the vessel moist. When the seeds begin to germinate, they should be sown. We have found it much better, instead of steeping the seeds in water, to place them between two layers of sand in shallow pans with drainage holes in the bottom. These are then placed in a warm room, both sand and seeds being thoroughly moistened with lukewarm water, and kept so until the seeds germinate. The pans should be as much as possible exposed to the light, only small pans should be used, and the seed should be placed in a very thin layer. The sand employed should be clean and loose, and when large quantities of seeds are treated in this way, they should be turned over and examined once every day or two to see whether they have begun to germinate or not. This method has the advantage of securing an equable condition of moisture, heat, and air, and of avoiding an excess of water, such as may occur in soaking. The results are consequently more certain, although they may be somewhat slower. A third method resembles that employed in the making of malt. The seeds are laid in heaps on dishes in a warm room and sprinkled daily with lukewarm water, are frequently turned, and covered with a light cloth. In this way large quantities may, with a great saving of trouble, be operated on, especially of such seeds as clover, red beet, &c. But it is more suited for agricultural purposes than for room culture. It is to be remembered that in all these methods the temperature must not be neglected. Seeds of tropical plants should not only be placed in the warmest part of the room, but the pot or pan containing the seeds should also be plunged in another larger one filled with moist sand, and placed on a stove heated to 120° Fahr. Seeds of plants of temperate regions and annuals if placed in the window of a heated room will enjoy the temperature that just suits them. Seeds of trees and perennials which grow in the open air may be sown in a room where the temperature is above freezing-point. A fourth method is that of soaking in hot water. The seeds are placed in a dish and water almost at the boiling point is poured on them. They are then placed in a warm room to cool. The effects of this mode are twofold. In the first place the hot water is in a lighter and more expanded condition, and therefore penetrates sooner and more completely into the interior of the seed, and in the next place it acts as a stimulant, especially in the case of seeds with hard skins or shells, such as those of New Holland Acacias, the Erythrinæ, Canna, Palms, Leguminosa, &c. It is with seeds of this kind that it should be chiefly employed. The seed of the New Zealand spinach (*Tetragonia expansa*), which is very tedious in germinating, should also be treated in this manner. But in the employment of this method care should be used, as the vitality of thin-skinned seeds would be completely destroyed by it. Moreover, too much hot water should not be poured on the seeds, so that they may cool the sooner, or if a large quantity is poured on them, so much of it should be poured off after a few minutes that only half of the seeds may remain covered with water. As soon as the water cools the seeds may be sown or layered until they germinate.

Instead of soaking hard-shelled seeds, they are sometimes cut or filed. But in this operation care should be taken not to injure the germ by cutting or filing quite through the shell. After being cut or filed, the seed is placed in lukewarm water, or layered, or else sown at once. Care should be taken not to make the cutting directly over the natural opening which overlies the germ in every seed. In seeds, especially those which are rather old, the germ lies in a hollow of the albuminous matter (as, for instance, in many Palm-seeds), and when they are cut or filed over this, the germ swells before moisture can reach the rest of the hard albuminous matter. The consequence is, that the young plant detaches itself from the albuminous matter, and is forced out of the seed. But as the albuminous matter contains the nutriment for the young plant in the earlier stages of its growth, when the germ is detached from it, it must perish. The writer has frequently experienced this, especially in the case of *Oreodoxa regia*, one of the Palms of tropical America.

CHEMICAL AIDS TO GERMINATION.

With old seeds, which have arrived at a condition in which it is difficult to excite their germinating powers, and with

others which are very tedious in sprouting, various chemical mixtures have been employed as stimulants. Water mixed with from the 1-400th to the 1-800th part of muriatic acid, sulphuric acid, oxalic acid, and phosphoric acid, has been found very efficacious, and unquestionably these acids, when employed in the above proportions, do promote the speedier entrance of moisture into the interior of the seed, and so produce a more rapid germination. But they, undoubtedly, do not possess the power which has been attributed to them of exciting fresh vitality in seeds which are already dead. The only advantage which the use of these acids possesses over that of soft river water is, that they bring about the germination of the seeds in a shorter time. The experience of the writer leads him to prefer the use of soft river water, as the results, although more tedious, are better and more in accordance with the operations of nature. Layering in sand we recommend as the best of all the methods even for old seeds. In special cases, hot water or cutting and filing may be employed, but experience is required to know when these should be used. Old seeds are mostly either quite dead, and so past recovery, or they are only very much dried up but still alive, as frequently occurs when they are brought from great distances, or when they are kept in dry warm rooms. In this case the germ of the seed is in much the same condition as a fully developed plant which is nearly dead from over dryness. If the latter is plentifully watered while in such a condition it is almost sure to die, while if it is gently and gradually watered, it stands a fair chance of recovery. In the same way the rapid entrance of water into dry seeds has a similarly injurious effect, and in their case the treatment with hot water, acids, cutting and filing, &c., should be avoided, and the more natural mode of layering in sand, by which moisture is gradually but effectually imparted, should be preferred. In fine, the only case in which hot water, acids, and cutting or filing should be employed is that of fresh, sound, hard-shelled seeds. Among the acids, oxalic acid is said to have a very powerful effect on old seeds. This is recommended not to be diluted, but the seeds are to be placed in the pure acid and allowed to remain there until they germinate. The miracles, however, which have been thus wrought on old seeds have, unfortunately, not been confirmed. In the seeds of conifers it frequently happens that they are covered with resin, which exudes from the skin and scales, and hinders the water from penetrating into the interior. These should be soaked in water to which some spirit of sal-ammoniac has been added, which will dissolve the resinous matter. We have before observed that there are many seeds of plants from cold regions which germinate with much greater certainty, when, after the water is poured off, they are exposed to a temperature below the freezing point. Such seeds, which have completed their ripening after being gathered in autumn, and have been kept dry through the winter, we recommend to be sown in snow. The same may be done with seeds of many of our finest rock-plants, as Gentians, Aretias, and other plants from the higher Alps. Snow should be gathered in a basin or saucer, and the seed sprinkled on the surface. The vessel is then either placed for some days in the open air, if the weather is frosty, or else put in some cool place where the snow will continue for some days in an unmelted state. After the lapse of from three to eight days, the snow may be allowed to melt under a temperature of 36° Fahr. The seeds are left to stand in the snow-water for twenty-four hours, and then sown. The seeds of many forest trees and perennials only germinate when, after falling in autumn, they drop into moist soil in which they pass the winter under a low temperature. These seeds should be similarly treated in cultivation, as all the previously-named modes of exciting germination are of no avail with them. The simplest plan is to sow them in pots in autumn as soon as they are ripe. The pots should then be exposed to the cold on a window-sill or balcony in the open air, and in winter placed in a cellar in a moist place, where the mice cannot get at them. If the cellar is dry, they should be kept moderately watered. In April they should be placed in a cool room on the window-sill and again watered. Germination will soon follow. Should they show any signs of germinating while in the cellar they should be removed into a well-lighted room, where the temperature is above the freezing-point. This

plan is recommended for the Liliaceæ and Umbelliferous plants among the perennials, and for the Pomaceæ, Amygdalaceæ, Rosaceæ, and Aceraceæ among the trees. As the amateur himself gathers but few of the seeds which he sows, but procures most of them in the course of the winter from the seed-shops, when it is too late for an autumn sowing, he should, immediately on receiving the seeds, layer them in moist sand, which is the best way to expedite their germination in the following spring. The vessel containing the layered seeds should be placed in a cellar, having been previously exposed to a temperature of from 28° to 20° Fahr. It should be in a position where the seeds will be safe from mice, and they should be turned once every three or four weeks, and in April should receive somewhat more water. As soon as some of the seeds are perceived to be germinating, the vessel should be removed from the cellar and the seeds should be sown. Seeds of crataegus, pears, apples, cherries, plums, &c., are best sown in nursery beds. For room culture we recommend this treatment in the case of lilies, and the amateur may also employ it in the case of single specimens of ornamental trees or shrubs which he may wish to raise.—*Dr. Regel.*

(To be continued.)

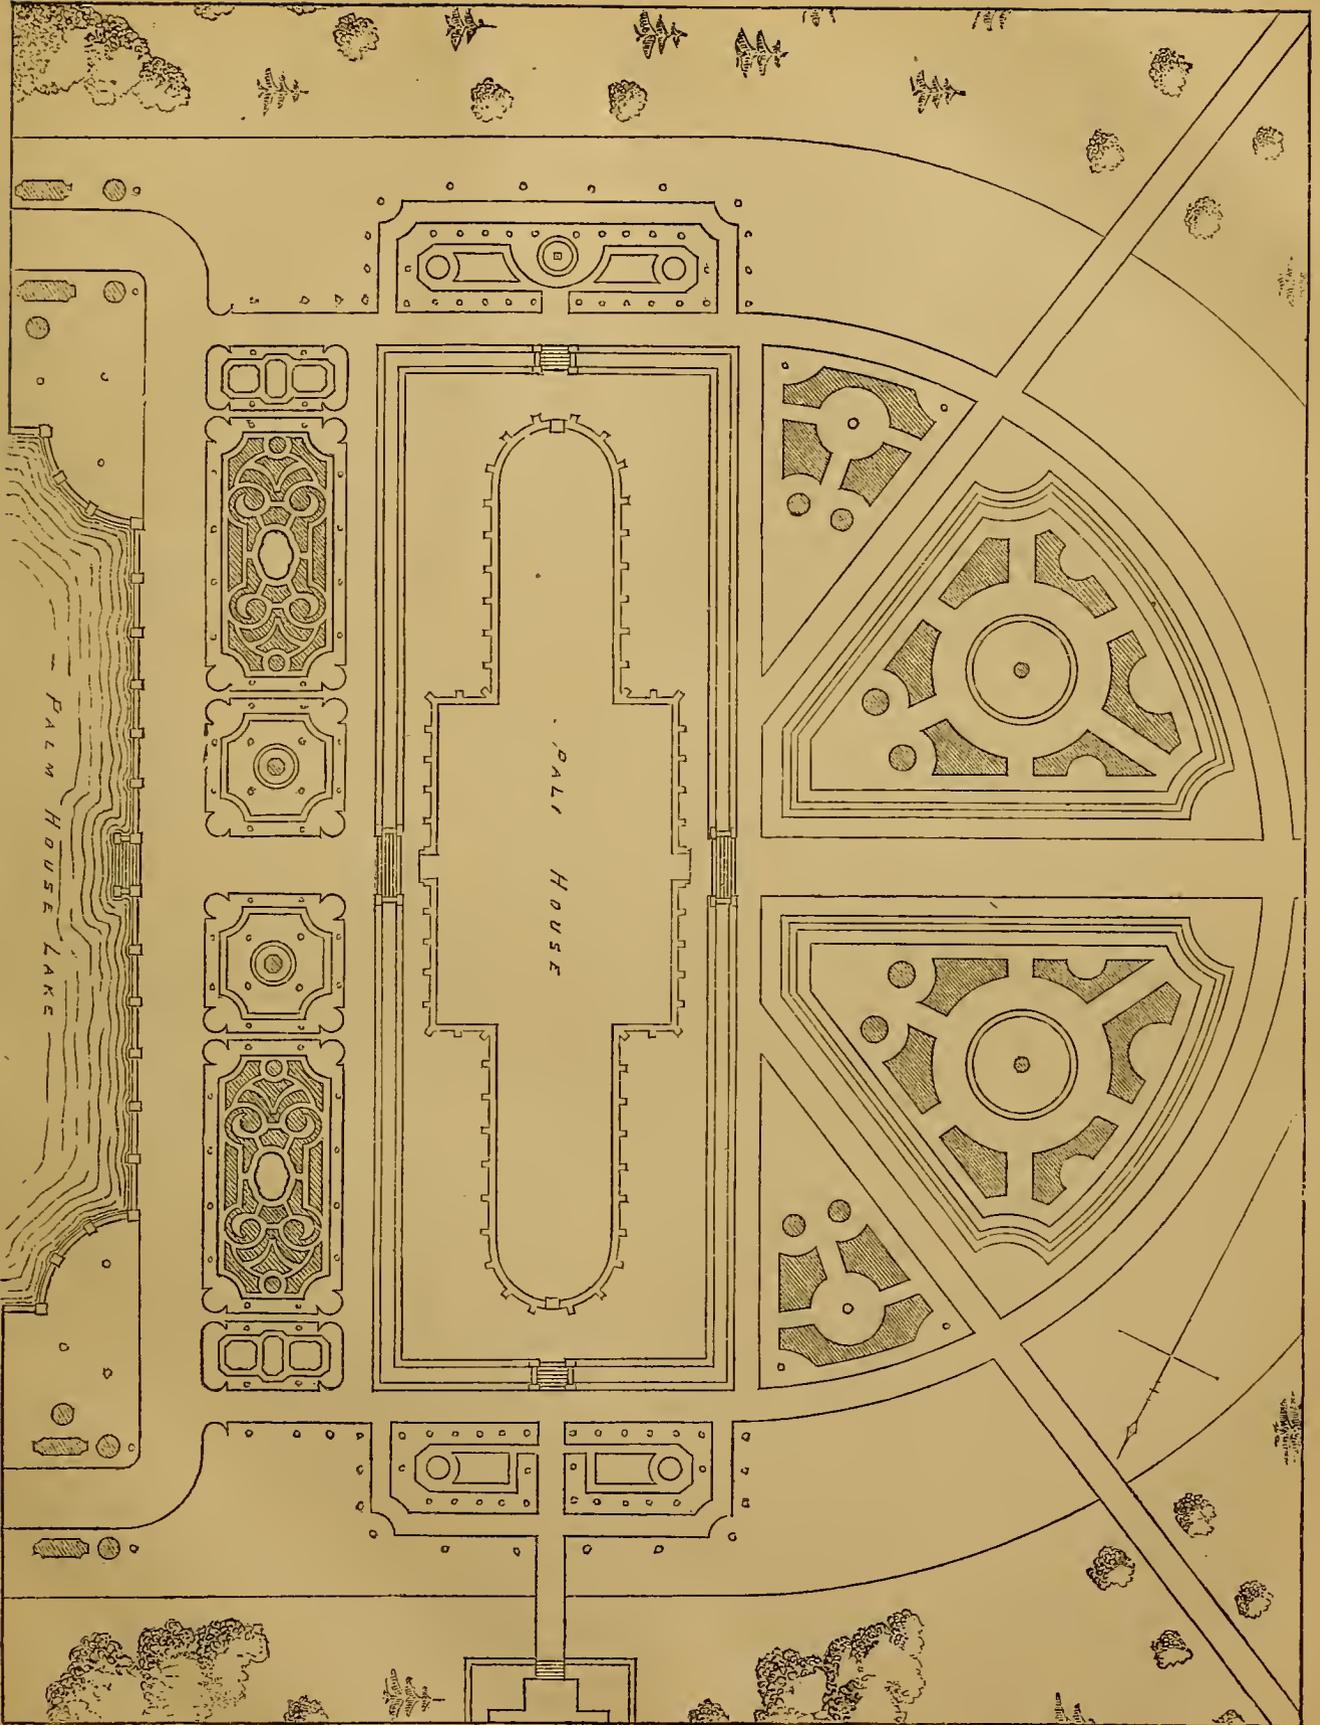

FLOWER GARDENS ROUND LONDON.

KEW.

For many years Kew has ranked among the most celebrated gardens about London for its summer decoration, though "bedding out" is not perhaps a very desirable feature of a botanic garden. The directors of the establishment have, however, been wise in ruling that this charm should not be lost to the thousands who visit Kew. We think that it is a most pernicious and foolish notion which supposes that a botanic garden should not be ornamental in the highest sense. This idea has, unfortunately, been so actively propagated in botanic gardens themselves, that now it is quite common to hear people speak as if the botanic garden proper were legitimately a sort of mummy chamber of the vegetable kingdom. It is "a mere botanical garden," you hear people say of one of our provincial public gardens, as if that statement were sufficient to prevent people expecting any high attraction in a gardening way. But this is an unnatural and unsatisfactory state of things, resulting mainly from the system of planting the subjects in their "orders" over the main surface of the garden. There is no possibility of a perfectly good arrangement so long as this is persevered in. At Kew, however, this particular fault is not at all apparent. The great service our botanic gardens, as distinguished from ordinary flower gardens, can render us, is to show the beauties of little-known plants. A grand field is open for them in this way. The great bar to progress in the way of variety in the private garden is a want of knowledge of good and varied plants, and the want of the plants themselves. But the botanical gardener both knows and has the plants, and, therefore, it is he who should lead the advance, not only in merely collecting plants of the most ornamental character, but also in showing the public how they may be arranged in the most tasteful way. In this way we think Kew might take a decided step in advance by, in addition to the mere bedders, taking up such comparatively neglected subjects as the Yuccas, Lilies, Irises, or grasses, and showing us what they are capable of effecting in the flower garden. So much for what might be; let us turn to what is.

It will be seen by our illustration that between the Palm House and the lake there is a little flower garden. This is usually very dressy, and, when seen from the Palm House terrace in the height of its beauty, it has a pleasing effect. The bedding plants employed here this season look very well, for, the ground being naturally light, this summer's moisture has caused them to start away and grow vigorously. The divisions to the right and left of the central squares are planted alike, or nearly so. In the central bed of each division is placed a vase filled with Geraniums, a few Lobelias and Tropæolums. From the base of these vases the beds are divided into four angular sections, by means of single lines of Centaurea, and each two opposite ones are filled alike, the whole bed being edged with blue Lobelia. The smaller beds contain no

FLOWER GARDENS ROUND THE PALM HOUSE AT KEW.

new feature, either in style of planting or in the plants used. The prevailing brilliance of scarlet too often found in gardens is, however, considerably relieved here by shades of pink and white Geraniums, the dwarf Ageratum, Lobelias, Verbenas, and some other plants more remarkable for foliage than flowers. Amongst the latter are *Centaurea ragusina* and *Coleus Verschaffeltii*, two plants which, when used in broad bands or masses, produce about the finest contrast that can be obtained in flower beds. Several other dark-leaved *Coleuses* are used, but none equal in effect to that just referred to. Another fine dark-leaved plant to be found in these beds is the *Iresine Lindeni*, which is in as good condition here as we ever saw it. It is used as an edging, and becoming too tall for that purpose is pegged down, thus forming a dense dwarf ribbon of a dark copper colour. Golden *Feverfew*, so useful for many purposes, is not used so lavishly here as we sometimes find it. Amongst flowering plants, Purple *Verbenas* seem to thrive admirably this season; owing to the dryness of the soil at Kew in warm weather, these do not give great satisfaction; they continue flowering most profusely for a while after being planted, but towards August their beauty is over. This year, however, they are making good growth, throwing up great numbers of flower spikes, clearly showing that a moist season suits them best.

In front of this little flower garden, along the side of the lake, are numbers of vases filled with *Geraniums*, *Lobelias*, *Nasturtiums*, and similar plants, put in early in the season in tin vessels corresponding with the size of the basin of the vases. When planting-out time arrives, after being properly hardened off, these plants, tins and all, are set in the vases, which at once become well furnished, and the plants employed receive no check.

Between the Palm House and Aquarium are some flower beds. In the centre of some very small ones standard *Roses* have been placed, and around their bases *Geraniums*, one kind only occupying each bed. Last year the larger beds were filled with *Cannas*, *Solanums*, &c., but this season the carpet system of bedding is adopted, the subjects used being *Golden Feverfew*, several kinds of *Alternantheras*, *Lobelias*, &c. With these an attempt has been made to represent a crown, or something of that kind, but it has resulted in a ridiculous failure.

The beds at the other end of the Palm House are mostly filled, but not very artistically, with succulents.

Let us now advert to the semi-circular part at the back of the Palm House. Here all the beds indicated in our illustration are filled with dwarf shrubs, excepting the central circles. In outside corners *Phloxes*, *Pentstemons*, *Gladioli*, and similar plants, infuse into these somewhat sombre-looking clumps a little floral beauty. On both sides of the walk that surrounds this half-circle, are long rectangular-shaped flower-beds, which are not seen on our plan, but which are filled as it were with "make-shift" plants. Some contain dwarf *Dahlias*, edged with *Golden Japanese Honeysuckle*; others *Hollyhocks*, edged with *Phalaris arundinacea variegata*; tall *Phloxes*, *Delphiniums*, &c., compose the bulk of the other beds, which are edged with different forms of *Viola*, and a few other dwarf plants. There are also a few sub-tropical plants in some, such as *Wigandias*, various sorts of *Solanum*, *Castor-oil* plants, *Cannas*, &c. Along the side of the Sion vista are a few beds filled with *Roses*, intermixed with dwarf *Dahlias* and *Mignonette*. Two rectangular beds on each side of the walk beside the steps coming down from the Palm House are edged with strong plants of *Centaurea*, the middle being dark red *Clove Carnations*. The *Centaurea* has grown with surprising vigour, so much so indeed that the *Carnations* are, as it were, encircled by a high wall. For such a position, surely, two better matched plants might have been found. The central circles consist of a raised grass terrace, on each of which is set a vase filled with flowering plants. A few curvilinear beds, a little way out from the vase, are edged at back and front with silvery-leaved plants, the main body of the beds being in mixed panel style, the panels consisting of little clumps of *Coleuses* and *Iresine*. The ground colour is scarlet and pink *Geraniums* and yellow *Calceolarias*, each running into the other, in no very definite pattern.

The plan of this flower garden, specially engraved for us, does not show a few of the recent modifications on the Sion side of the Palm house, but these are of no importance. As to the

beds themselves, we have no hesitation in describing them as bad, and this for several reasons. But the main fault is their overcrowding. There is not only no breadth and no peace, but the object of the designers would seem to be deliberately to destroy these. Many of our readers, will, however, be glad to possess a plan of the flower garden at Kew.

THE FRUIT GARDEN.

FRUIT KEEPING.

A cool temperature of 40° to 45°, with as little variation as possible, is the chief point. All sudden changes must be fought against; they induce decomposition. If the temperature of a fruit room falls under 40°, that of the fruit will be considerably less, and much of the water left in the air will be condensed on the fruit. Especially is this the case during changes from frosts to thaws. All such alternate dryings and dewings of the fruit tend to hasten its decomposition, and must be guarded against as much as possible. The only sure antidote is a regular temperature of about 45°. Various suggestions have been offered for insuring this regularity of temperature. Fruit is often stored in dry cellars, which are well adapted for the purpose; though the temperature in these will average 50°, still, being so regular and subject to no surface change, fruit often keeps well in such places. Others prefer lofts almost wholly isolated from the ground; but these, unless the roofs are protected with double ceilings and thatched coverings, are apt to be too warm in summer and too cold in winter. Perhaps the best place of all would be the middle rooms in large buildings—cut off alike from the earth and the air, the windows fitted with double cold-proof shutters, and the walls built hollow to keep out both heat and cold. But as such mild quarters are seldom available for fruit storing, one of the commonest arrangements is to build a double-walled building in a dry cool position facing the north, and to protect the roof with thatch, double ceilings, &c., so as to render it wholly frost-proof, without the aid of fire heat. The latter is most mischievous in fruit rooms, and should never be introduced, unless in the coldest climates. Another plan of making double walls frost-proof is to fill the space between them with dry chaff or sawdust. If these materials are used in a dry state, and they are kept dry afterwards, it is astonishing how much frost four or six inches of such slow conductors will defy. Others prefer an empty cavity between the walls, as confined air is one of the slowest conductors of either heat or cold. Another means of making the walls of fruit rooms heat or cold proof is to thatch the ordinary walls with a thick layer of dry straw, and cover this again with boarding. Such double or treble walls are better—that is, less penetrable—than those of solid brick. All these modes of preventing cold or heat from passing through walls are equally applicable to the roof. Our care will be thrown away if, while the walls are so carefully protected, the sun is allowed to pour his heat, or the frost its cold, in through the roof. Only of secondary importance to this evenness of temperature is freedom from damp. This is one great advantage of forming fruit rooms on the second or third floors of buildings. But it is also possible to get away from damp on the ground. By choosing a dry site, by thorough drainage and impervious concretes, such as a flooring of asphalt, or compounds of tar and cements, the damp may be shut out as well as the cold. These objects gained, all else is simple and easy. Proceed to shut out the light also by the use of thick wooden shutters. Light, like heat, stimulates fruit, hastens maturity, and consequently is favourable to decomposition. Experience proves that fruits keep best and longest in the dark. I would further add, the less ventilation the better. A still pure air is the chief thing needed, and unless our senses reveal its impurity, it may remain for weeks or months unchanged. If it be needful to ventilate fruit stores, the time should be chosen when the external and internal temperatures are nearly alike, and the weather is clear and dry. As to the mechanical arrangements of fruit rooms, as long as they are clean, convenient, ample, and sweet, little more is needed. Cleanliness is essential. Everything without and within should be without spot. Dirt is the fruitful matrix of decomposition. Convenience is a primary consideration in places that are visited daily. I have seen fruit huddled into almost inaccessible shelves, and placed well-nigh beyond reach. The shelves are often too wide, and packed too closely together. In a room, say ten feet wide, there is no better arrangement than a path of four feet wide down the centre, and the sides arranged in shelves three feet wide and twenty-eight inches or two feet from one to another. The most distant fruits are thus placed within easy reach, and selection or examination presents no difficulty. Another point is amplitude of space. All the best fruit should be displayed singly. To

heap one, two, or three layers on to each other is deterioration or ruin to superior fruit. Common kitchen fruits destined for immediate consumption have often to be heaped together in seasons of plenty, but no superior apples or pears expected to keep should ever be so treated. The old mode of sweating fruit to improve its quality was a practice in direct league with rottenness, and is now generally abandoned. Even the packing of fruits into jars, in drawers, in paper, or other non-conductors is not to be commended. In suitable storehouses, display the fruit in single layers, without squeezing or overcrowding, and it will keep its full time in the best possible condition. Finally, the fruit must lie on a flavourless bed; straw, hay, moss, paper, wadding even, are better dispensed with. There is no bed equal on the whole to clean, smooth-planed, white deal, unpainted. Poplar also forms a flavourless bed, but after a few years' use its softness invites the attacks of fungi. White, and as far as possible knotless, resinless deal, forms the best fruit shelves. Perhaps the best form is in scantlings two inches wide, with one inch space between them. The fruits then rest on the deal, and are well-nigh enveloped with the air of the room. Glazed earthenware and glass likewise make good fruit shelves. Having thus stored our fruits in a place of safety, all that is needed is a weekly examination. As soon as a speck of rottenness appears, out with that fruit; and if by any oversight a fruit should go on rotting unseen, lift it out with the utmost care, for fear of sowing the spores broadcast over others. Beyond this care let the fruit alone. The less it is handled or moved the better it will keep. D. T.

OUR FRUIT CROPS.

ADDITIONAL REPORTS.

Sion House, Brentford, Middlesex.—In this neighbourhood outdoor fruit crops are very unsatisfactory. Of Peaches and Nectarines we have scarcely any. Apricots, none. Apples, very few. Pears, moderate; some trees having a fair crop, others none. Plums, almost a failure. Cherries, a medium crop. Strawberries, Raspberries, and black Currants, plentiful. Red Currants and Gooseberries, very thin.—J. WOODBRIDGE.

Chirk Castle, Cheshire.—The failure of the fruit crop is general throughout this neighbourhood, owing to the severe frost we had in the end of May. Of Apples, we have none. Pears, a fair crop on walls only. Plums and Apricots, a failure. Peaches, Nectarines, and Strawberries, fair crops. Raspberries, a failure. Cherries, a fair crop on walls only. Currants, a failure. Gooseberries, a fair crop. Filberts, a failure.—W. ROSE.

Wiley, Broseley, Shropshire.—With me Apricots are very thin, but good in quality; Peaches, moderate; Nectarines, good in some places; Apples, very good in some places, none in others, but with me early ones are very good; Pears, abundance generally; Plums scarce; Cherries good; Filberts and nuts very scarce; Damsons are good in sheltered situations, none in others. In this immediate neighbourhood, where local report says the Prune Damson originated (Brittian's Lane), they are plentiful. All bush fruits, Gooseberries, Currants, Raspberries, and Strawberries, were plentiful with me, but scarce and much blighted in the neighbourhood.—Wm. WELCH.

Belvoir Castle, Leicestershire.—Stimulated to action at an early period of the year by weather of unusual mildness, fruit trees were more than usually susceptible to the ungenial influences of cold, gloomy, and frosty weather which occurred at the critical period of blooming. Root action paralysed and the flow of sap arrested are consequences that result from ground chilled and soddened by wet. The healthy progress of fruit trees was checked by influences that affected both the root and blossom, and the unhappy results have been not only a failure in fruit crops, but a wretchedly unhealthy and blighted condition of the trees during the spring and early summer. The Apple Crop is the worst I have known for several years, and a portion of the Apples scantily found on the more sheltered and best situated trees is more or less deformed. Pear trees, trained to walls and growing in well-drained well-tilled borders have produced good crops. I gathered Jolimont on an unsheltered wall on the 18th July; Jargonelle is hearing well, Marie Louise abundantly, and we have full crops of Bon Chrétien, Crassane, Winter Nolis, Orpheline d'Enghein, Bergamotte Esperen, and others. Standard trees have generally failed. The Apricot crop has failed completely. Plums, with the exception of a few Victoria trees on walls, bearing partial crops, have failed. Morello Cherries have borne well on north walls, but were much affected by black aphid. Currants, Gooseberries, and Raspberries, scarcely half crops. Strawberries very abundant and fine, but destroyed by heavy and incessant rains in July. Walnuts and Filberts have failed.—W. INGRAM.

Shardeloes Gardens, Amersham, Bucks.—The outdoor fruit crop in this neighbourhood is a failure generally. Apples, scarcely any. Pears, half a crop. Plums and Apricots, none. Peaches and Nectarines, very few. Currants and Gooseberries, one-third of a crop. Strawberries and Raspberries, good. Figs and Nuts, a few. Walnuts, none. Morello Cherries, half a crop; other sorts, a third of a crop. Damsons, half a crop.—THOMAS BAILEY.

Wortley, Yorkshire.—With the exception of Strawberries, Raspberries, and Cherries, which have been an abundant crop, and other small fruits which have been moderately good, this has been the worst year for outdoor fruits here I have ever known. Apples, Pears, Plums, and Apricots are a failure. Heavy falls of snow about the middle of May, and frosts and unkindly weather for some time afterwards, destroyed our prospects of a crop, which up to that date was most promising, especially Apples. Aphides and other insects have been more destructive than usual, particularly after cold weather set in in May. Owing to the sultry weather in June and July, the growth of trees and shrubs has been much more luxuriant than usual. The rainfall up to this date, August 6th, is 36 inches, or about 3,636 tons of water to the acre, and most of that has fallen lately.—J. SIMPSON.

Wolverston Park, Ipswich, Suffolk.—I never saw greater promise of an abundant crop of outdoor fruits than the trees presented this year. Cherries, Pears, and Apples were literally loaded with bloom. The latter was nearly all cut off by the late spring frosts and the trees much crippled, and they have since been badly infested with caterpillars. Cherries appeared to set well, but the fruit was frost-bitten and became deformed, and a large portion of the crop fell. Peaches are a very thin crop; the young leaves became sadly blistered, owing to the sudden transition from cold frosty nights to bright sunny days. The blistered foliage was picked off, and advantage taken of warm afternoons to give a gentle syringing, and the trees have made fair wood and are tolerably healthy. Pears set wonderfully well, so much so, that in many cases we have had to remove quite half the crop; but many are deformed and spotted. Plums are a fair crop on west walls, but thin on other aspects. Apricots are almost a failure, but the trees look well, and appear to have suffered less than Peaches and Nectarines, and are tolerably free from gum. Early varieties of Strawberries, such as Keens', were a full crop; Queens were thin, deformed, and small. Raspberries have been a heavy crop, but those early in bloom were small and deformed. Currants were thin, owing to the attacks of aphides on the bushes last season, denuding them of leaves in July. Gooseberries rather thin; Figs the same. Nuts abundant.—JAMES SHEPPARD.

THE FINCHLEY VINE.

ONE of the finest vines in the country is now in full bearing in Kaye's nursery at Finchley. It is not so large as either the Hampton Court or Cumberland Lodge vines, much smaller, in fact; but in point of size of bunch neither of these, nor any other vines we are acquainted with, approach it. The Cumberland Lodge vine is considerably finer than the Hampton Court, and bears about two thousand bunches, looking meanwhile as if cribbed and confined for room, as the shoots reach the extremity of the great house, and are there cut off, just as we are obliged to do in small vineries; but one of the Finchley bunches is as large as two of those at Hampton Court and Cumberland Lodge. The curious part of the matter is that no unusual pains were spent upon the making of the border in which this fine vine grows. It is made on a hard clay bottom, a considerable quantity of brick rubbish being placed on that part, with a slope to a drain at the front of the border, which is about fifteen feet wide. It is not quite raised above the level of the surrounding ground, as most borders are with our great growers. The soil of the border is not that choice kind of loam recommended by most writers on the vine, but just the top spit which had been cleared off building ground in various parts of the district—now and then very sandy, occasionally of a stiff and unctuous clayey texture, with here and there a lot of brick rubbish, in short a mixture of the better kinds of earth and rubbish which are so easily obtained in a suburban or other district where much building is going on. The border is about four feet in depth. No manure is mixed with its ingredients, except what little may descend from the remains of the annual winter covering of stable manure with which it is protected during the winter and early spring months. The house is eighty-nine feet long by eighteen feet wide, span-roofed, and heated by hot-water.

The vine enters at the middle of one side, and goes across the roof, making five equal breaks, or, in other words, sending five fine opposite branches to each end of the house. The base of the main stem is of great thickness. It quite fills the house, and would no doubt furnish three times the superficies it now does if the house and border were sufficiently extended. It bears four hundred bunches of grapes, weighing from 1½ to 2 lbs. each. The attainment of the result we have mentioned by simple means is well worthy of record. It surely proves that vine culture of the highest character is a much more simple affair than amateurs and many practical horticulturists believe it to be. If the amateur, instead of building a few distinct small houses, would erect a good roomy one, and cover the roof with vines, it would give much more satisfaction than is often attained by those who have not much time or attention to devote to glass houses. A large span-roofed vinery of the sort might be made to afford a very agreeable promenade in winter, a home for considerable quantities of greenhouse and bedding plants, shelves for early-potted strawberries on each side, room for a fine bloom of chrysanthemums in autumn, and not a few other things for which special structures are often provided. In summer, when the fruit would be ripening and the foliage occupying the roof, we care very little for the indoor garden, and are usually too glad to leave it, while the plants we have named must for the most part be out of doors or in frames. We recommend vine-growers, who have the opportunity, to see the Finchley Vine during the ensuing fortnight.

Wiring Garden Walls.—The French system of placing wires over walls, or in any position in which it may be desired to have neatly trained fruit or other trees, having become now of frequent use in England, and as the *raidisseur* used to tighten the wire often cuts or breaks it, I think the following plan preferable and cheaper. At the extremities of the wall nail pieces of wood similar to garden sticks about an inch square, and drive eyed nails or hooks about ten feet apart in the wall; fasten the wire to a small staple driven into the wood at one end of the wall, pass it through the eyed nails, and secure and tighten it at the other end by a common joiner's iron screw about an inch and a half long, through which a hole has been previously drilled near the top end to receive the wire and hold it in its place whilst the screw is driven fast into the wood in the usual manner. By this means the wire can be made as tight or slack as you choose; whilst with the *raidisseur* another turn is perhaps necessary, and as the wire cannot bear the strain, it breaks.—C. POCKLINGTON, *West Skirbeck*.

Vine Budding in August and September.—In this operation the bark of the vine stock should be cut clean off, according to the size of the bud to be put on, inserting the lower end of the bud in a slit, so as to keep it firm. I have practised this kind of budding on the laterals of old vines for five years, but the results were not satisfactory, until I discovered that the last week in August or first week in September was the best time to perform the operation, and also that each bud must be protected from the drying influences of the atmosphere by bandages of cotton wool or other similar material, which have to be kept constantly wet for three weeks. Unless this is done, budding of vines will not be satisfactory, and people who profess to have budded vines never have done them satisfactorily. I do not call successful budding that which gives you only one "take" in half a dozen, or perhaps more, and no fruit even from that; but if budding in September is managed properly, every eye will take, and show fruit just as freely as the natural buds of the vine. The wood should be in a half-ripe state, and pliable, so as to bend uniformly upon the cut that it is to cover.—Z.

Pinching the Shoots of Fruit Trees.—The principal rule to bear in mind is this—pinch the strongest shoots first, and only those which are near the top of the tree; a week afterwards take those lower down, and so on in succession until all have been done. Never denude the tree of much foliage at once. Pinch the most vigorous portions of the tree most, and allow the weaker to grow a little longer. Thus the shoots at the top of a pear tree on a wall should be pinched to three or four eyes, while at the bottom of the wall they should be allowed five or six.

Manuring Fruit Trees.—Don't manure your fruit borders, is frequently the advice given to inquirers; under certain circumstances the advice is good, such as in newly-made borders of rich turf, strong soils, and in low situations; but to follow such advice on light sandy soils or porous gravelly subsoils and high localities, would be wrong, and would lead to nothing but disappointment. Under these circumstances, good rotten manure I will not say *may* be used to advantage, but *should* be used liberally for fruit trees of every kind, and especially for peach trees.—F.

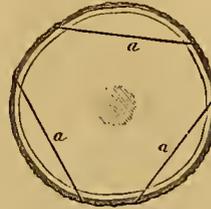

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from p. 106.)

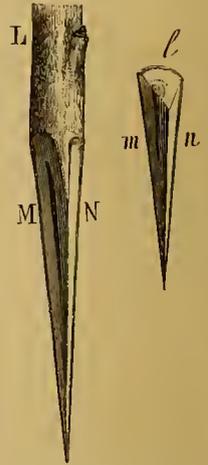

OBLIQUE CLEFT-GRAFTING.

LOOKING to its future development, a stock that is already pretty strong may be furnished with more than two grafts; but as we can place only two in one transverse cleft, we should have to make other clefts across the centre, the result

Section of the stock.

of which would be to enfeeble the stock. To avoid this we can employ a method which will leave intact the heart of the tree, and at the same time allow us to augment the number of the grafts. The stock having been sawn across and smoothed down with the pruning-knife, we make several clefts at the side (*a, a, a*), which, to speak geometrically, are, with reference to the section of the cutting, chords in the circle, and not radii or diameters. In order that the scion (*L*) may be adapted to the incision in the stock, it must be cut obliquely, so that while only one of its sides (*m*) slants towards the centre, the other (*n*) will only have the bark removed as far as the albumen. In the other methods of ordinary cleft-grafting those scions which have too much pith may always be cut in this way: in that case the stock is cleft obliquely and not diametrically, in order to spare the central part.

Mode of Cutting the Scion for Oblique Cleft-grafting.

SEASONS FOR ORDINARY AND OBLIQUE CLEFT-GRAFTING.

The principal seasons for cleft-grafting are spring and the end of summer. In the south of France, where the winters are very mild, it is practised with success from the month of December. Towards the north they seldom commence before March or April. In those districts where growth is prolonged, the summer-grafting is very often done in the autumn. Thus there are two distinct seasons, known in practice under the names of spring grafting and autumn grafting.

SPRING GRAFTING.—March and April are the usual times for the first cleft-grafting. In warm countries it may begin earlier as it may in the case of subjects of very early growth. The scion-branches, cut beforehand, are to be placed in soil, or in a vessel full of sand, and deposited at the north side of a building, or in the shade of a tree or bush. They may also be removed from the parent-tree at the time of grafting, provided the sap has not yet begun to flow in them. The stock should be headed down on the day of grafting. When this is done sooner, the cut has to be renewed, in order that the scions may be inserted upon a healthy and fresh surface. If there is any difference in the state of the sap of the two parts, the scion should not be so advanced as the stock. After grafting, should there be a continuance of great heat, the graft must be covered with moss, or a piece of paper twisted into a cap placed over and fastened to the stock.

AUTUMN GRAFTING.—Cleft-grafting in autumn or the end of summer is performed in the same way as in spring. Nothing is changed but the season. This period comprises the months of August, September, and October; but the moment should be seized when the sap is on the decline, the branches of the stock well ripened, the buds well formed, and the leaves, although still adhering, are ready to fall. If grafted too soon, the scion might sprout, and this precocity in the end of the season would be fatal to it in winter, as it would be more exposed to the cold than if it had remained dormant. On the other hand, if grafted too late, the scion could no longer unite with the stock, on account of the disappearance of the cambium, and when spring arrives it would be found to be

withered. So we cannot lay down an invariable rule for the time proper for each species or variety; the condition of growth is the point on which success chiefly depends. Two neighbouring subjects of a similar species may demand a difference of three weeks in their autumn grafting. In this matter use is the best guide. Among the subjects grafted in autumn, the plum, and especially the wild cherry, are the better of it in this respect, that, their development in the following April being much earlier than if grafted in spring, they will have less to fear from the vicissitudes of the weather and the attacks of insects. The scions should be cut just before being used, stripped of their leaves at once, and have their ends placed in a vessel of water or in cool sand. In autumn grafting cold mastics have this drawback, that their unctuousness suffers from the action of the frost, which extends itself to the tissues of the grafts. A warm composition which hardens at once should therefore be employed. However, a mastic which is too easily softened or which does not harden sufficiently can always be covered so as to protect it from the frost.—*C. Baltet.*

(To be continued.)

EASY WAY OF STRIKING CUTTINGS.

As it will soon be time to begin striking cuttings to supply young plants for next season, perhaps a few hints on the easiest way of doing so may prove of use to some of your readers. It is a great mistake to leave such work till late in the season; late struck cuttings are never strong or well rooted, and when winter comes on, are liable to die off, whereas those struck early become nice strong young plants. I have begun making mine; I did so at the same time last season, and during the winter I did not lose more than two or three dozen plants out of a large number. I have bedded out nearly two hundred dozen plants this summer that I struck last season. I always strike my Pelargoniums, variegated and all kinds, out in the open border. One is always sure to have some spare spot that can be utilised in this way. Then in the first or second week in September I take them up and pot them, and when the time comes to take them in they will have become well established. My Lobelias, Petunias, &c., I strike in wet sand in common saucers or little shallow pans. These I fill with the sand, wet it, and then I prick in my cuttings. I never let the sand get dry, and in a few days my cuttings are ready to pot off. This is a sure way of striking cuttings, and you can strike them by the hundred—I was going to say, by the thousand—in these little saucers, as they may be pricked in as close as they will stand. By treating cuttings as just directed you will find them to give little trouble, as those out in open borders will not of course require the watering and shading, &c., that they would do if they were in pots in the greenhouse or in a pit, and those in the pans will root so quickly that you will be surprised at the number you can raise in succession in this way. A. H.

Upper Norwood.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.

PRIVATE GARDENS.

Conservatories.—Camellias for early blooming that have completed their growth and set their flower buds too thickly have the weakest of them removed, leaving only as many as the plant can properly carry with advantage. If Camellias are now allowed to suffer from want of water, they may go on apparently all right, and their flower-buds may swell as if nothing had happened, but when the blooming season has arrived, the buds will in many cases drop off. Late-flowering Azaleas are still subjected to a warm genial temperature and free use of the syringe, whereas in the case of those that flowered early, and which have completed their growth and are forming flower-buds, the overhead sprinklings are gradually lessened and the atmospheric temperature lowered. All pinching in of the young shoots of Azaleas, Coronillas, Cytisuses, and similar plants is now discontinued, it being undesirable to cause them to form more young wood this season. The branches of Fuchsias grown on trellises are regulated, and in order to make them produce flowers and wood more freely, the borders are frequently watered with

guano or other manure-water. It is desirable to induce them to produce as much bloom as possible before the end of September; after that time they are gradually cut down, and the borders are kept dry, unless other plants are associated with them. Tritonia aurea is at present one of our gayest conservatory flowers, and it only requires a short stake or two and abundance of water to maintain it in fine condition for a considerable length of time. Coleuses are stopped at every third or fourth joint, in order to keep them bushy, for under even partial shade they are apt to become leggy. Erythrinae done blooming are turned outside and gradually dried off.

Orchids and Ferns.—Orchids which have large pseudo-bulbs require less water than others, but in the case of all kinds the supply of water is now a little diminished. Shading, unless when absolutely necessary, is discontinued. Tree fern stumps on which small Polypodiums, Davallias, and similar ferns are growing are daily syringed in order to insure a sufficient supply of moisture. A fine effect is often produced by covering the trunk of a tree fern with variegated Ivy, intermixed with several little Pterises, Adiantums, and other Ferns, together with Selaginellas of the Martensii section.

The Flower Garden and Shrubbery.—The heavy rains which we have lately had have been detrimental to flower gardens. Verbenas, and similar plants, have speedily covered the beds, and have flowered well, but the blooms are a good deal spoiled. Foliage plants have, however, done well. Iresine Lindenii has seldom been seen so fine as it is this season. Yellow Calceolarias near London have been a complete failure. Geraniums are being propagated, but not in the open border to such an extent as usual, for the late heavy rains have considerably damaged those already put in out of doors. Verbenas and Heliotropes are still being propagated. For these a pit about eighteen inches in depth is made towards the end of June or first of July, and is filled up with half-decayed leaves mixed with litter, the whole being firmly packed together and covered over with light sandy compost, over which is put a thin layer of sand. This induces a gentle bottom heat, and affords a suitable medium for late propagating. Hollyhocks from this year's sowings are being transplanted into well manured deeply worked borders, keeping them about eighteen inches apart, so that they can be lifted safely with good balls for transplanting. Pansies that are rooted are being transplanted into borders or into nursery lines farther apart than the cuttings stood. Wallflowers and Sweet Williams are always most satisfactory when treated as biennials; they are, therefore, now being transplanted from the beds in which they were pricked out to where they are to bloom, or else set farther apart than they formerly were, so that they may be safely transplanted next spring. Annuals are being sown just now for late blooming, and ground is being got ready for such as are intended for spring flowering. Where variegated Kales are used for winter decoration they are being transplanted; it is best to keep them in rather light soil than otherwise, for under such circumstances they become better coloured. Bulbous plants such as Ixias, Tritonias, Sparaxis, &c., are being lifted, but the different tribes of Lilies are left untouched, as they thrive best when left year after year undisturbed.

Indoor Fruit Department.—Vines done fruiting are encouraged to ripen their wood; a steady temperature and moderately dry atmosphere are maintained in houses in which fruit is ripening. For Melons a brisk temperature is maintained, and they are allowed plenty of air and water. A little powdered charcoal is placed around the necks of the plants to prevent rot, which so often attacks them there especially in dull weather. In frames the fruit is placed on pieces of wood, slate, stone, or tiles laid on the beds; those on trellises are supported on pieces of suspended board. Some of the Cucumber frames are having their linings renewed. Figs are divested of all suckers that spring from the root, and which are likely to rob the fruit of its proper nourishment. When crops of Peaches and Nectarines have been gathered, such trees as are in pots are commonly set outside on a well-sheltered border. Some, however, do not turn out their pot plants, but keep them always indoors, giving them as much air as they possibly can. Tomatoes in pots are kept as near the light as possible, and are supplied occasionally with weak manure water. Chillies in fruit-houses and frames are also kept near the glass. To these green-fly is a great enemy; they therefore now and then need a dip into a mixture of diluted tobacco-water in which a little soft soap has been dissolved, or they are laid on their sides in a close frame and fumigated in the evening, removing them next morning and heavily syringing them.

Hardy Fruit and Kitchen Garden.—The shoots of young espaliers are regulated from time to time, so as to keep the trees in proper form. As regards early fruits, do not gather them too early; when that is done they seldom attain their real flavour. On the other hand, they must not be allowed to get over ripe, for that is quite as bad as too early gathering. Avoid, too, harvesting them during the hot or sunny portion of the day. With regard to vegetables

a small sowing of Cauliflowers may be made where the plants can be protected through the winter; but the main sowing should not be made for a few days yet. A sowing of Cabbages was made about the 5th of the month, where ground permitted the seed to be got in; but where it could not be sown then owing to the ground being unworkable, no time must be lost in getting it in. The late crop of Broccoli has, in most places, been planted out about two feet apart each way. A main crop of the prickly Spinach has also just been sown, and to succeed it another will be made about the 20th or 24th of this month. Endive for a late crop has just been sown. Turnips are being thinned. A few of the white turnip-rooted Radishes are sown, and also some of the white and black Spanish kinds for late autumn and early winter use. Chicory is thinned out to three inches apart. Lettuces, as they get strong, are being tied up in order to cause them to heart. Tomatoes planted against walls are kept nailed and stopped, removing all unfruitful laterals, and pinching out the points of the main stems when a sufficiently large crop has been set. Onions for standing the winter and for salading are being sown on well-drained soils.

NURSERIES.

Indoor Department.—Cuttings of Geraniums are being struck in frames or cold pits. The old plants are cut up into as many pieces as will make cuttings, and the finer kinds are inserted singly in small pots. Centaureas are increased under handlights and in frames. Lobelias for seed are kept in cool and airy houses, and the pods gathered as they ripen. The finer kinds of Tropæolums are increased by means of cuttings placed thickly in a four or six inch pot, a size convenient for winter storage. Such Alternantheras as remain after the summer sales, are kept in any odd corner, and partly starved, in order to make them more capable of undergoing the hardships of winter; some consider that these give more satisfaction than young plants, as they winter better and yield a great quantity of cuttings in spring. Daphnes are being grafted in intermediate houses, the plants being placed on their sides in frames within the house, which are kept closely shaded. The operation of grafting Camellias and Epiphyllums is also being carried out. Fern spores are being sown in pots half filled with crocks, over which sandy peat is placed, so as to rise a little above the rim of the pot. When sown, the plants are placed in close moist frames, and are covered over with bell glasses. Young Palms in seed pans are being potted singly into small pots. Young Erythrinias are now placed outside. Eranthemms and Gymnostachyum are being increased by means of cuttings. Sonerilas, lately layered, are now being separated and repotted, using for the purpose a compost of rough peat, sphagnum, and sand. Pitcher-plants are being examined, and any that require it are top-dressed; they like plenty of heat and moisture.

Outdoor Department.—In some cases budding is finished, but in many instances a good deal has yet to be done. The young stocks being in lines about two feet apart, one man goes over them, making an incision and inserting the buds, and another comes after him and ties them up with matting or worsted. The training of young fruit trees occupies a good deal of attention, for where they are thickly planted in the rows every alternate plant is trained along the lines, the others across. Hoeing and weeding occupy also a considerable amount of time, especially amongst seedlings and thickly transplanted lines of young conifers and other shrubs. Herbaceous plants are being increased by means of cuttings or layers. The finer kinds of Periwinkle are being divided into small rooted tufts and planted a few inches asunder in nursery lines twelve inches apart. Phloxes, such as frondosa, Nelsoni, and others of that class, are being divided into little rooted crowns and inserted thickly in lines about nine inches apart. Young Phloxes, belonging to the tall section, are being repotted from the cutting pans into small sixty-sized pots, using a compost of yellow loam, leaf-mould, and a little sharp sand. Pinks and Pansies lately put in under handlights, now that they are fairly rooted, have the lights removed. Bedding Violas are being taken up, divided into as many pieces as will make nice little plants, inserted in lines a few inches apart, and protected for a time with mats supported on hoops or stakes, or are covered with frames in order to throw off drenching rains. Pansies are never planted where the ground is apt to be saturated with stagnant water in winter. Seeds of herbaceous and annual plants are now being carefully harvested.

MARKET GARDENS.

The chief marketable crops just now are Vegetable Marrows, Cucumbers, French Beans, Lettuces, and Onions. During chilly days the pits in which the Cucumbers are grown are shut up a little earlier than in bright weather. Vegetable Marrows are still growing apace, and bearing abundantly; even plantations made late exhibit considerable progress, and are rapidly covering the ground. From Tomatoes in snug corners a few fruits have been obtained, but

as a rule they are not yet ripe; they, however, promise to produce plenty of fine fruits. The Newington Wonder French Bean is still the greatest favourite. What are called Runner Beans are extensively grown for a second main crop; they afford more bloom than the dwarf Bean, and consequently more fruit. These do not grow quite so tall as the Scarlet Runner. The white-flowered kind is grown in preference to the red, as it is said to set better; both are, however, largely planted. They commonly yield, in fine seasons, from six to ten pods on each spike; but if the weather is unfavourable to their setting, they seldom produce more than two. The main late crop of Celery has just been planted in lines five feet apart, forming, as it were, four-foot-wide beds and one-foot alleys, in which the Celery is planted. Between the lines of early planted Celery the intermediate cropping of Lettuces is now being tied up to blanch, and some of them are removed for market, leaving only the line of Cauliflowers along the centre. Ground just cleared of a crop of Cauliflowers is well manured, dug over, and the surface made a little level by means of harrowing it. A portion of this ground was sown the last week of June with early Cabbages, and the other portion the first week of this month with the same. The ground just vacated by the removal of the Potato crop is being planted with Waleheren Broccoli, previous plantings of which are meeting in the rows although two feet apart; these, together with the others being planted, are all expected to yield a crop before the severity of winter sets in. Ground for Spinach sowing is being prepared. A sowing of the prickly was made about the 10th of this month, another will be about the 20th or 24th, and one the second week in September. The first two sowings furnish abundance of leaves throughout the winter, and the last one comes in useful just before the first crop of spring-sown smooth-leaved Spinach is ready. Spring-sown Onions, which still continue to grow, are being pulled and carted to market. All Potatoes are removed for market except such as are required for home consumption and seed. Radishes are being sown as required in cool moist situations; the produce of these sowings is said to be as good as early spring Radishes.

COVENT GARDEN MARKET.—August 16th.

Flowers.—Japan Lilies, now finely in flower, are abundant; as are also bell flowers, more especially Campanula pyramidalis, and Cockscombs. Conspicuous amongst fine-foliaged plants are India-rubber trees, young Palms, and Dracænas. Crotons, singularly enough, one seldom sees, while Screw Pines are seldom absent from the Central Row. Cut flowers, both from hardy and tender plants, are now abundant, especially white and fragrant kinds, which are used in the best bouquets.

Fruit and Vegetables.—Hardy fruits are being largely imported from the Continent, home-grown produce being comparatively scarce. Prices are, therefore, high, compared with what they generally are. Gooseberries and Currants of different kinds still make their appearance; as soon as they arrive, the best fruit is selected for dessert, the rest is sold at low rates for cooking purposes. Among indoor fruits, Grapes are the best. Melons are for the most part inferior in flavour. Pine-apples are good, large, and plentiful. Cucumbers, although supplied in large quantities, are a good deal tinged with yellow; good straight specimens of them realise twice as much as crooked ones. Chillies and Tomatoes are coming in in abundance. Among vegetables the commoner kinds are sufficient for the demand. French Beans and Vegetable Marrows especially are very plentiful. Root crops are also furnished in good condition. Onions present, as yet, little signs of ripening.

THE GARDEN.

“ This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE.”—*Shakespeare.*

THE SIX OF SPADES.

CHAPTER XIX.

Mr. Chiswick on Bedding-out (continued).

ARRIVING, we shall be as surprised and delighted as Cinderella herself,—

“ When tapers shone,
And music breathed,
And beauty led the ball.”

Surprised! Why there is not one in a thousand, even of those who love a garden—nay, there is not one in a hundred of my brother gardeners, who knows the marvellous charms of a spring garden extensively and tastefully arranged; and, had I power and permission, nothing would please me more than to act as a sort of horticultural Mr. Cook, of unbounded benevolence and wealth, to superintend gratuitous excursions of the floral fraternity to Belvoir, Cliveden, Wardie Lodge, and elsewhere, from the middle of March to the end of April. Our vernal flowers have gone gradually, but in many cases entirely, from our gardens. His reverence told us, a few Sundays ago, that people nowadays were quite as fond of telling and hearing new things as ever they were at Athens when St. Paul was there; and this love of novelty and display has been at work in our guild, and induced us to despise and discard the fair and faithful favourites of the past.

Two of the songs with which our old friend Mr. Grundy has occasionally entertained us always remind me of our disgraceful and perfidious misconduct, as gardeners, with reference to hardy flowers. In his “Labourer’s Song,” one rustic complains to another,—

“ Folks thinks still
Nowt’s good now as used to was,
My owd friend Bill.”

And there has been a sad season, not long past, in horticulture in which few cared for that which all could have, and all things old were vile. In another melody he tells us how the proud ploughboy, on his promotion, cruelly cuts his former friends:—

“ And little Nell, I loved so well,
And walked so wi’ o’ Sundays,
Good lor, says I, don’t talk to me,
Ise mon at Mestur Grundy’s!”

So, I fear, it has been in many cases with the gardener. He was promoted to serve in houses of glass; he was introduced to gorgeous company; he was wooed by a more brilliant and aggressive beauty; and he forgot, as he gazed upon Stella’s glowing charms, the sweet little modest Polly-(anthus), whom once he “loved so well.”

But again I say “surprised,” for who can pass from the external gloominess of an English March, the leafless hedges, the brown fallows, the slaty clouds, the flowerless gardens, into a scene of the liveliest loveliest beauty, and not feel surprise? And delight! such a sudden and sweet refreshment! I remember, when I lived near London, being in a crowded omnibus one sultry summer’s day in the Strand, with the large mother of a thirsty babe on the one side and a German Jew, who had not been smoking the sort of tobacco which I like, on the other. I was feeling about as comfortable as a Croton in a coal-pit, and was literally gasping for breath, when the omnibus, having made an unusual progress of nearly eighty yards, drew up just opposite one of those narrow streets which lead from the great thoroughfare to the Thames, and a cool, fresh, delicious breeze from the river blew upon my heated brow! Such a revival to the floral spirit is the first sight of the flowers of spring.

Recall the charming diversity of colour and of form which they, the annuals, perennials, and bulbous plants of spring, present to our admiration. Of form, from the tall imperial *Fritillaria*, having the resemblance of crown and of sceptre also, to the prostrate *Stonecrop*, carpeting the ground beneath.

Of colour, what a range, what a rich variety! All colours, primary and intermediate, brilliant and soft, positive and neutral—colours to harmonise, colours to contrast, the colours which I like, and the colours which you like—all of them are here. Does your eye delight in the glow and brightness of the more vivid tints? Look at that *Anemone*, well-named “fulgens,” all afire in crimson glory! Regard these *Tulips*—General Garibaldi, in his scarlet uniform, or royally named and royally appareled, *rex rubrorum*, the King of the Reds! Gaze upon that *Gentian* (the vernal), luminous, gleaming like the breast of a humming bird with an intense and dazzling blue! Watch that clump of the yellow *Crocus*, as they open to receive the kisses of the sun (if any); and what is there in the stove, or even in the summer garden, in *Orchid*, *Allamanda*, or *Calceolaria*, which can vie with them in their golden sheen?

Or have you what is called a more “quiet taste”? Bend over this bed of *Myosotis dissitiflora*, bluer than the turquoise, blue as the heavens, and you need not ask from the gardener, or search in floral dictionary, a translation of the name, for the flower itself speaks it in your ear and whispers, “Forget-me-not.” Or turn to that patch of the exquisite, dainty, little *Scilla* (“from the Scilly Islands,” I once heard a gentleman, who set up to be a wit, remark to a lady, who promptly set him down by replying, “Did you come over in the same ship?”), or to that sheet of roseate *Silene*, blue mountain *Anemone*, purple *Pansy*, pale yellow *Primrose*, bright yellow *Cheiranthus*, lilac *Aubrietia*, or (yet more appropriate to one who is talking of sheets) to those snow-white masses of *Candytuft* (*Iberis correaefolia* is the fairest of the fair), of *Alyssum*, *Arabis*, *Saxifrage*, *Daisy*, and *Snowdrop*.

Now glance at the combinations; at that bed of golden *Feverfew*, dotted here and there with the purple *Crocus*; of white *Candytuft*, from which at intervals the bright red *Hyacinths* rise; or of *Cerastium*, with small circular patches of *Scarlet Anemone* or *Cliveden Pansy*, or of *Erica carnea*, with the golden *Arabis* intermixed; or of *Sedum acre aureum*, with white and red *Tulips* inserted à la pincushion. Would you have something more striking and effective even than these? Copy two beds, which I first saw at Belvoir and shall never forget; the one of

“ *Daffodils*,
Which come before the swallow dars, and take
The winds of March with beauty;”

intermixed with purple *Hyacinths*; and the other of *Aucuba japonica*, which was blended with the many-coloured *Kale*. So impressed was I with the latter combination, that Mr. Ingram, a gardener worthy of that princely place, and one who, like the Castle by which he dwells, “hath a pleasant air” and, like a true artist, a kind brotherly sympathy with all who love his art, noticed my interest and gave me some seed. This was sown at once, came up, was transplanted, and finally placed, in the autumn, in a bright bed of healthy young *Aucubas*, selected for the purpose. Alas, alas! one moonlight February night, that footman, whom I never could admire, although his calves were grand, left the gate between the park and the pleasure-ground open; and when I went to take a last look at my fires, the cattle were on my flower-beds chewing their cuds, and their cuds were composed of my variegated *Kale*, which they had brutishly mistaken for *Cow Cabbage*!

I have no time to speak of harmonies and gradations in colour, of rings, ribbons, pyramids, and baskets; but I must say a few words about foliage, because I have heard some folks, who should know better, say that, prate as we may about spring flowers, we can speak nothing in praise of spring foliage. No praise! Why, after admitting a defeat in the darker leafage and sounding a retreat on our *Creeping Bugle* (*Ajuga reptans*) before the *Coleus*, *Amarantus*, *Iresine*, and *Beet*, and after a further concession that we have no single leaf so beautiful as Mrs. Pollock, we advance our whole army for a general engagement, with no fear of the result, and, in the poetical words of *Transatlantic fervour*, “we pounds the univarse smart.” What foliage is so attractive in the summer garden as that of the gold-tipped *Stonecrop* (*Sedum acre aureum*), of the *Daisy*, which has leaflets of green and gold (*Bellis acubæfolia*), or of the exquisite variegated *Thyme*? Is not the golden *Feverfew* brightest in spring? Are not the

variegated Arabis, Euonymus, and Periwinkle, the silvery Cerasium, Centaurea, Gnaphalium, and Santolina, most beautiful in their early growth? When is the Dactylis, or our old friend the Gardener's Garter, so silvery or so graceful as in spring? Stoop now to admire this variegation of white and of gold in *Lamium maculatum aureum*, of green and silver in that charming *Spiræa*. And now regard the manifold varieties of "that rare old plant, the Ivy-green," forming such a natural floor or cincture for the smiling splendour of the spring!

And all the while, what fragrance from Violet and Primrose, from Hyacinth and Wallflower,* from *Daphne Mezereon*, and Thyme! Mr. Ingram plants large beds of his Russian violets near the entrance gate of the Belvoir garden, to breathe a welcome to the visitor, but from all parts of it sweet incense rises heavenward.

I have said nothing of the flowering trees and flowering shrubs, which should form a part of all spring gardens, surrounding them, and here and there forming centres for the beds; the blossoming fruit trees, Peach, Almond, and Cherry; the Laburnums and Syringas, the Rhododendrons and Azaleas, the Weigelas, Ribes, and Berberis. I have passed over hundreds of bonny winsome flowers. Volumes might be written, volumes have been written, about them.

There yet remains to be mentioned, and that with thankful praise, the most gracious and precious attribute of these bright vernal flowers—they can be multiplied quickly and abundantly, and they scarcely need any cultural care. Many of them cover the ground with wonderful rapidity, and send out roots as they spread. Thus they are propagated readily by division, and most of them by cuttings and by seed also. They are just as beautiful and enjoyable in single plants by the cottage door as in masses nigh the mansions of the rich. Like all the best gifts of our merciful Father, *they are for all*. They demand neither money nor time. All they ask is, that we will look on them and love them with

"Pure eyes and Christian hearts."

S. R. H.

(To be continued.)

DANGER IN OUR "DUCK-PONDS."

THE ugly duck-pond-like pieces of artificial water, which so often disfigure our pleasure-grounds, are sometimes the cause of fatal accidents to children. A sad affair of this kind has recently occurred in a private garden in Berkshire, and an acquaintance of our own has lately lost a boy eight years of age in the same way, in Sefton Park. The *Times* very fittingly heads its last report of a case of this kind "Criminal Carelessness." These accidents result chiefly from the ugly and stupid way in which the margins of our artificial waters are made. Instead of the bank gradually sloping into the water, as is usually the case in natural lakes, it is frequentlyhipped in an abrupt manner, leaving the water generally too deep at the margin. All artificial waters near a house, or in any position where there is danger of children falling into them, should be made very shallow at the margin. The bank of turf should slope easily and gradually into the water, never jump abruptly out of it, and the bottom should slope easily and gradually from the margin. So arranged, it is almost impossible that an accident can happen. And it is worthy of notice that the truest art and perfect safety go hand-in-hand in this case, for the common abrupt margin is an eyesore, and wrong in every way.

EVERYTHING about Leicester Square has long been bad enough, but a few months back the wildest imagination would have had some difficulty in realising its present condition. Bands of tumblers entertain audiences of some two or three hundred people, who often completely block up the east side of the square. Yesterday a man was swallowing knives and evolving reels of cotton from his ears, to the infinite amusement of a vast crowd. The ground itself presents the most dilapidated and unsightly appearance, worn into deep ruts, and strewn with blocks of paving stones. The horse is a particoloured of red and white, and covered with placards. Not a policeman is to be seen.

* "Very delightful," as Lord Bacon says, "to be set under a parlour or lower chamber window."

NOTES OF THE WEEK.

— THE playground which the Marquis of Westminster has presented to the children of Pimlico, in Ebury Square, was thrown open to its juvenile possessors on Monday last.

— RECENTLY some Black Country excursionists unlawfully entered the fruit gardens in the Vale of Evesham, consumed great quantities of fruit, and injured the trees a good deal.

— LOVERS of hothouse bulbous plants will be interested to learn that *Crinum McKenii*, a fine new kind from Africa, is now in flower in Mr. Bull's nursery. The flowers are white tinged with pink, and very large in size.

— THERE is, we are informed, a large display of very fine Asters now in perfection in Mr. Chater's Nursery at Cambridge. They are interesting as the result of a peculiar mode of cultivation, on which we hope to say a few words by and by.

— THE finest hardy perennial we have noticed flowering during the week is *Chelone obliqua*, a plant now seldom met with in London gardens. It grows about a yard high, and the flowers are large and of a lovely rosy purple colour.

— THE beautiful "Scarborough Lily" (*Vallota purpurea*), is growing and flowering in one of the sub-tropical beds in Battersea Park. Its stout scapes, well furnished with erect-growing scarlet flowers, distinguish it from its associates, few of which can be compared with it for brilliancy of colour.

— AT the thirty-third annual meeting of the Royal Botanic Society last week, it was reported that the total receipts of the present year amounted to £8,619 15s. 6d., a sum much in excess of the money received last year. The number of new fellows admitted during the year was 104.

— A HANDSOME Everlasting Pea, a seedling, the result of a cross between the rose and white kinds, is now in fine bloom in the Gonville Nurseries, Cambridge. It is named *Lathyrus latifolius*, var. *Chateri*, and is a profuse bloomer, the flowers being white flushed, and delicately striped, Carnation-fashion, with purplish rose; altogether a desirable addition to our Everlasting Peas.

— IN America, as is well known, Indian Corn is eaten at every table in the green state, and a delicious vegetable the "green corn" is. It is used in various ways, but is by preference eaten from the cob or head. A recently arrived Hibernian, who was greatly taken with it, and had greedily bitten off all the sweet soft pea-like grains, called out to the "help," "Waither! come and pnt more pais on my stick."

— LORD EBURY, Sir Francis Lycett, Mr. Thomas Brassey, M.P., Mr. Thomas Baring, M.P., Mr. David Chadwick, M.P., Mr. James Figgins, M.P., Captain Douglas Galton, C.B., Messrs. R. Dudley Baxter, G. L. Banks, Blanchard Jerrold, Hodgson Pratt, and James H. Rigg (Wesleyan Training College), have joined the Lord Mayor's Committee for the purchase of the Alexandra Park, and the development of the property in the interests of the people.

— REFERRING to Mr. Smith's gift of seats for the Thames Embankment, one of our morning contemporaries writes:—"What seems most wanted now is some covered place where people, waiting for the boat, or enjoying the air, might take refuge from rain and snow. If any wealthy citizen seeks for pure glory—and in consequence of constitutional reasons declines to emulate Mr. Stanley in penetrating Africa—we advise him to pnt us up in many parts of London, arcades and shelter-seats like those of Bologna, Hastings, and Milan. We shall forget many great men, but never that noble citizen who does this kindness for wet and windy London."

— A BEAUTIFUL and very distinct species of *Gladiolus* (*purpureo auratus*) is at present flowering in the open border in Mr. William Bull's nursery at Chelsea. The flowers are more cup-shaped than in the ordinary forms of *Gladioli*, and are of a greenish sulphur-yellow colour, the three lower petals having bold and distinct stripes of rich dark violet running along their centres. The spikes are richly clothed with blooms, which, in the case of well established plants, will doubtless be of good size and very effective. The whole character of the plant is, however, less robust than that of our ordinary kinds of *Gladioli*.

— THE Bradford Corporation, who already hold two spacious and beautiful parks—Peel Park and Lister Park—have just purchased Low Close Farm, consisting of more than 17 acres of land at Horton, at a cost of £9,000, with the intention of forming, with the addition of adjoining land, a park of 30 acres in that district of the borough. This will constitute the third park of the Corporation, and it is intended to increase the number of parks for the borough to five, by forming another one in Bowling, by the immediate purchase of land for the purpose, and by converting the waste land of Bradford moor into a recreation ground.

— AMERICANS assure us that a Cabbage-leaf in the crown of the hat is a preventive against sunstroke. The expense is not extravagant.

— ONE of the best hardy shrubs in flower at present is *Clethra Michauxii*, a member of the Heath family. Plants of it may be seen in the pleasure grounds at Kew, producing racemes of fragrant white flowers in abundance. The Kew plants are between four and five feet high.

— THE Lambeth Vestry are endeavouring to prevail upon the Board of Works not to let two pieces of land on the Albert Embankment for building purposes, but to keep them open and plant them ornamentally in a similar manner to those already planted on the Victoria Embankment.

— THE Scammony (*Convolvulus Scammonia*) is this year flowering very freely in the Royal Botanic Gardens, Regent's Park, in the cold clay of which it has lived for a good many winters. The flowers are white with a yellowish tinge, and are produced in such numbers as to render the plant a conspicuous hardy climber.

— GREAT destruction has been caused by a cyclone to the clove plantations of Zanzibar. This island, lately brought into notoriety as the place whence news of the discovery of Livingstone came to the civilized world, seems to have been devoted almost wholly to the cultivation of cloves. But this industry, as, indeed, all others, has been prostrated by the completely destructive tornado in question. Cloves, in consequence, have increased in price.

— A LARGE number of Australian, Californian, and English fruit trees has been introduced into different parts of India; the Neilgherry Hills, in particular, bid fair to become a nursery of trees. English Oak has been reared at Ramikhet (the new military cantonment on the Kamaon hills); indeed, the rearing of fruit and forest trees is becoming a favourite recreation, and will probably prove a lucrative employment.

— ONE of the finest specimens of *Nepenthes Rafflesiana* that ever graced a London flower show, was exhibited last Wednesday at a meeting of the Royal Horticultural Society, South Kensington, by Mr. T. Baines, of Southgate. The plant was set on a pedestal, around which clustered some five dozen pitchers, which, as regards size, were more like pint jugs than the pitchers one usually sees on such plants. This fine plant excited, as well it might, the admiration of all who saw it.

— LOVERS of Phloxes and Pentstemons would now be repaid by a visit to the Lea Bridge Road Nurseries, where splendid collections of all the finest varieties of these fine families are now in blossom. There are also now in flower in the same nursery some new German Verbenas, which are particularly noticeable for the brightness of their colours and for their fragrance. They are likewise, owing to their robust habit and profusion of blooms, well adapted for bedding purposes.

— BY an Act of Parliament which has just received the Royal assent twenty-four acres of Crown land, lying on the north-east and south sides of Victoria Park, have been rescued from the encroachment of bricks and mortar, and in consideration of the payment of £20,450 by the Metropolitan Board of Works, have been transferred from the Commissioners of Her Majesty's Woods, Forests, and Land Revenues to Her Majesty's Commissioners of Works, to be by them laid out as a recreation ground for the people for ever.

— THE first of the public drinking-fountains erected at Paris by the munificence of Sir Richard Wallace has been recently inaugurated on the Boulevard de la Villette. In form it is a small square monument, ornamented with four statuettes at the foot, sustaining a dragon-scale dome, and it is provided with two goblets fastened by a chain. This is the type for isolated fountains in squares and avenues. The other type designed for attachment to walls is of oval form and less ornamental.

— THE spread of the Potato disease is unfortunately becoming general. Concerning the crop in Lincolnshire, Mr. John Algernon Clarke says:—"Around Long Sutton I found that already three-fourths of the tubers (by weight) are diseased. The testimony of many is that scarcely any sound Potatoes can be discovered, and the general anxiety is to know, not what may be the probable amount of 'ware' for market, but whether produce enough will be forthcoming as 'seed' for next year. The same condition of the crop prevails over the entire tract of Potato country between Boston and Wisbeach, where the yield will be doubtless little more than a return of the seed planted. If the saleable produce of the entire Potato crop of the British Isles is all but destroyed, the loss means something like 1,630,000 acres (besides gardens) at, say, $4\frac{1}{2}$ tons per acre, amounting to 7,335,000 tons, which, at £4 per ton, comes to £29,340,000." Let us hope, however, that the result may not be quite so disastrous as that the entire crop should be lost.

THE HOUSEHOLD.

MODES OF COOKING COMMON MUSHROOMS.

THE peasants of a great portion of Europe eat mushrooms raw, with salt and dry bread, and wholesome and good they are. The true flavour of mushrooms, nevertheless, is greatly heightened by cooking; and cook them how you may—a broil, a stew, or a fry, with the simple addition of butter, salt, and pepper, and they are excellent. There is one rule that should always be observed in whatever mode they are cooked, and that is that they should be served up quickly and hot. The following modes of cooking mushrooms may prove useful at this season of the year:—

TO STEW MUSHROOMS.—Trim and rub clean half a pint of large button mushrooms; put into a stew-pan two ounces of butter, shake it over the fire till thoroughly melted; put in the mushrooms, a teaspoonful of salt, half as much pepper, and a small piece of mace pounded; stew till the mushrooms are tender, then serve them on a hot dish. They are usually sent in as a breakfast dish, thus prepared in butter.

MUSHROOMS À LA CRÈME.—Trim and rub half a pint of button mushrooms, dissolve two ounces of butter rolled in flour in a stew-pan; then put in the mushrooms, a bunch of parsley, a teaspoonful of salt, half a teaspoonful each of white pepper and of powdered sugar, shake the pan round for ten minutes, then beat up the yolks of two eggs, with two table-spoonfuls of cream, and add by degrees to the mushrooms; in two or three minutes you can serve them in the sauce.

MUSHROOMS ON TOAST.—Put a pint of mushrooms into a stew-pan, with two ounces of butter rolled in flour; add a teaspoonful of salt, half a teaspoonful of white pepper, a blade of mace powdered, and half a teaspoonful of grated lemon; stew till the butter is all absorbed, then add as much white *roux* as will moisten the mushrooms; fry a slice of bread in butter, to fit the dish, and as soon as the mushrooms are tender serve them on the toast.

CURRIED MUSHROOMS.—Peel and remove the stems from a dish of full-grown mushrooms, sprinkle with salt, and add a very little butter; stew them gently in a little good gravy or stock. Add four table-spoonfuls of cream, and one teaspoonful of curry powder, previously well mixed with two teaspoonfuls of wheat flour; mix carefully, and serve on a hot dish, with hot toast and hot plates attendaut. Mind the "curry stuff" is good, says an Indian friend, and not too much of it. The word "curry," by itself, it seems, being merely the Tamil word for "meat." The large horse mushroom, when half or three parts grown, and curried in this fashion, will be found to be delicious.

TO POT MUSHROOMS.—The small open mushrooms suit best for potting. Trim and rub them; put into a stew-pan a quart of mushrooms, three ounces of butter, two teaspoonfuls of salt, and half a teaspoonful of Cayenne and mace mixed, and stew for ten or fifteen minutes, or till the mushrooms are tender; take them carefully out and drain them perfectly on a sloping dish, and when cold press them into small pots, and pour clarified butter over them, in which state they will keep for a week or two. If required to be longer preserved, put writing paper over the butter, and over that melted suet, which will effectually preserve them for many weeks, if kept in a dry, cool place.

TO PICKLE MUSHROOMS.—Select a number of small, sound, pasture mushrooms as nearly as possible alike in size; throw them for a few minutes into cold water; then drain them; cut off the stalks, and gently rub off the outer skin with a moist flannel dipped in salt; then boil the vinegar, adding to each quart two ounces of salt, half a nutmeg sliced, a drachm of mace, and an ounce of white pepper-corns; put the mushrooms into the vinegar for ten minutes over the fire; then pour the whole into small jars, taking care that the spices are equally divided; let them stand a day, then cover them.

ANOTHER METHOD.—In pickling mushrooms, take the buttons only, and while they are quite close, cut the stem off even with the gills, and rub them quite clean. Lay them in salt and water for forty-eight hours, and then add pepper, and vinegar in which black pepper and a little mace have been boiled.

The vinegar must be applied cold. So pickled they will keep for years.

MUSHROOMS EN RAGOÛT.—Put into a stew-pan a little stock, a small quantity of vinegar, parsley, and green onions chopped up, salt, and spices. When this is about to boil, the mushrooms being cleaned, put them in. When done, remove them from the fire, and thicken with yolks of eggs.

MUSHROOMS AND TOAST.—Peel the mushrooms, and take out the stems. Fry them over a quick fire. When the butter is melted take off the pan. Squeeze the juice of a lemon into it. Let the mushrooms fry again for some minutes. Add salt, pepper, spices, and a spoonful of water, in which a clove of garlic, having been cut into pieces, has soaked for half an hour; let it stew. When the mushrooms are done make a thickening of yolks of eggs. Pour the mushrooms on bread fried in butter, and laid in the dish ready for them.

MUSHROOMS EN CAISSE.—Peel the mushrooms lightly, and cut them into pieces. Put them into cases of buttered paper, with a bit of butter, parsley, green onions, and shalots chopped up, salt and pepper. Dress them on the gridiron over a gentle fire, and serve in the cases.

MUSHROOMS À LA PROVENCALE.—Take mushrooms of good size. Remove the stems, and soak them in olive oil. Cut up the stems with a clove of garlic and some parsley. Add meat of sausages, and two yolks of eggs to unite them. Dish the mushrooms, and garnish them with the forcemeat. Sprinkle them with fine oil, and dress them in an oven, or in a *four de campagne*.

BAKED MUSHROOMS.—Peel the tops of twenty mushrooms; cut off a portion of the stalks, and wipe them carefully with a piece of flannel dipped in salt. Lay the mushrooms in a tin dish, put a small piece of butter on the top of each, and season them with pepper and salt. Set the dish in the oven, and bake them from twenty minutes to half an hour. When done, arrange them high in the centre of a very hot dish, pour the sauce round them, and serve quickly, and as hot as you possibly can.

MUSHROOMS AU GRATIN.—Take twelve large mushrooms about two inches in diameter, pare the stalks, wash, and drain the mushrooms on a cloth; cut off and chop the stalks. Put in a quart stew-pan an ounce of butter and half an ounce of flour stir over the fire for two minutes; then add one pint of broth; stir till reduced to half the quantity. Drain the chopped stalks of the mushrooms thoroughly in a cloth; put them in the sauce with three table-spoonfuls of chopped and washed parsley, one table-spoonful of chopped and washed shalot, two pinches of salt, a small pinch of pepper; reduce on a brisk fire for eight minutes, put two table-spoonfuls of oil in a *sauté* pan; set the mushrooms in, the hollow part upwards; fill them with the fine herbs, and sprinkle over them lightly a table-spoonful of raspings; put in a brisk oven for ten minutes, and serve.

MUSHROOM SOUP.—Take a good quantity of mushrooms, cut off the earthy end, and pick and wash them. Stew them with some butter, pepper, and salt in a little good stock till tender; take them out, and chop them up quite small; prepare a good stock as for any other soup, and add it to the mushrooms and the liquor they have been stewed in. Boil all together, and serve. If white soup be desired, use the white button mushrooms and a good veal stock, adding a spoonful of cream or a little milk, as the colour may require.

BREAKFAST MUSHROOMS.—Clean a dozen or so of medium-sized, place two or three ounces of nice clean beef-dripping in the frying pan, and with it a table-spoonful or more of nice beef gravy. Set the pan on a gentle fire, and as the dripping melts place in the mushrooms, adding salt and pepper to taste. In a few minutes they will be cooked, and being soaked in the gravy and served upon a hot plate, will form a capital dish. In the absence of gravy, a *souppçon* of "extractum carnis" may be substituted.

MUSHROOMS WITH BACON.—Take some full-grown mushrooms, and having cleaned them, procure a few rashers of nice streaky bacon, and fry it in the usual manner. When nearly done, add a dozen or so of mushrooms, and fry them

slowly until they are cooked. In this process they will absorb all the fat of the bacon, and with the addition of a little salt and pepper, will form a most appetising breakfast relish.

MUSHROOM STEMS, if young and fresh, make a capital dish when the supply of mushrooms is limited. Rub them quite clean, and after washing them in salt and water, slice them to the thickness of a shilling, then place them in a saucepan with sufficient milk to stew them tender; throw in a piece of butter and some flour for thickening, and salt and pepper to taste. Serve upon a toast of bread, in a hot dish, and add sippets of toasted bread. This makes a light and very delicate supper dish, and is not bad sauce to a boiled fowl.

Lemon Peel.—Many persons may not be aware that the scent and flavour which constitute the use and value of lemon peel reside in minute cells, close to the surface of the fruit, and that by slicing it thin they will cut through these innumerable cells, and thus obtain double the quantity of the essential oil that could be procured by any one careless or ignorant of this circumstance. The cells being cut through, it necessarily follows that a great part of the oil remains on the white of the lemon. This is easily abstracted by means of rubbing a lump of sugar over it. The process of rubbing the *unwounded* peel is a tedious process, which may be facilitated by the thin cuttings above named. A slice of peel cut into the white is of little use, as the cells, being entire, retain the oil.

Macedoine des Fruits.—Take whatever fruit is at hand of the softer kinds—Currants (red, white, and black), Strawberries, Raspberries, Cherries, Grapes, whichever are in season, and in as great variety as possible, for it is the mixture of flavours that, as in the case of the salad, makes the *macedoine*; strip and pick it all carefully, and mix it together in a salad bowl or any other deep vessel, strew over the whole finely powdered loaf sugar, and over this a very small quantity of claret, sherry, or even water. This must be done an hour or two before the *macedoine* is to be eaten; give the fruit a careful stir so as to disseminate the syrup equally over all, and the lover of fruit will find a new enjoyment; the syrup will have crept into every corner of the luscious flesh. Eaten alone the *macedoine* is a delicious dessert; with a fresh roll it makes a capital *entremét*. Small stone fruit, such as greengages, apricots, and peaches, may be added to a *macedoine*, being first halved and the stones taken out.

Blackberry Wine.—The following is an American recipe for making blackberry wine: Crush the berries with a wooden pestle in a wooden tub or bucket; draw off all the juice, and add to it an equal quantity of water and two pounds of refined sugar for each gallon of the mixture. Keep in jars till fermentation is complete, and then bottle and cork it up. A second fermentation will take place in the ensuing spring, during which another pound of sugar should be added to each gallon. The wine thus prepared will keep well, and improve with age.

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM AUGUST 15TH TO AUGUST 21ST, INCLUSIVE.)

BY OUR OWN REPORTERS.

Achnatherum	Centranthus	Hydrocotyle	Passiflora
Calamagrostis	macrosiphon	bonariensis	racemosa
Adenophora	Chelone	Hydrangea	Pezomum
stylosa	obliqua	hortensis	Hammala
Allium	Chrysocoma	japonica	Penstemon
declinatum	latifolia	Hypericum	campanulatus
Amaryllis	Cirena	zygoticum	cordifolius
Belladonna	alpina	oblongifolium	Polygonum
Aralia	Clematis	Iberis	cuspidatum
nudicaulis	tabulosa	linifolia	viviparum
Arctotis	Coreopsis	Lavatera	Potentilla
breviscapa	longipes	mauritanica	dahurica
Artemisia	triplex	Linnaea	Pycnanthemum
rupestris	Cornus	borealis	linifolium
Aster	albus	Linum	Salpiglossis
casubicus	Epilobium	maritimum	sinuata
obliquus	Hallerii	Lobelia	Sedum
Richardsonii	Eragrostis	cardinalis	dentatum
Atriplex	Purshii	Melica	Selschianum
hortensis	Eupatorium	altissima	stenopetalum
Bromus	verticillatum	ciliata	Solidago
pendulinus	Francoa	Ophiopogon	Riddellii
Calamitha	rupestris	japonicus	Thalictrum
glabella	Galatella	Origanum	microphyllum
grandiflora	discoidea	sipyleum	Tricyrtis
Callirhoe	Glycyrrhiza	Oxalis	pilosa
involverata	fetida	purpurata	Valeriana
Campanula	Hebenstreitia	Paronychia	officinalis
floribunda	linifolia	serpyllifolia	

Plants in this list are almost without exception such as have come into bloom during the past week.

THE FLOWER GARDEN.

THE HERBACEOUS SPIRÆAS.

THIS extensive genus includes several species characterised by the beauty of their foliage and the airy grace of their flowers. Of the larger herbaceous kinds, none perhaps is more striking than *S. Aruncus* (Goat's-beard), a vigorous perennial which grows from three to five feet high and flowers in summer, producing its numerous small white flowers in long spikes forming a terminal panicle. The leaves are tripinnate, the leaflets being in three or four pairs, oblong, acute, serrated, about two inches long and one inch broad, with a terminal one of ovate shape and usually larger than the others. It is found in various parts of Europe, Asia, and America, and is a valuable subject for grouping with other fine-foliaged herbaceous plants, thriving in ordinary soil, and easily multiplied by division of the tufts.

A rather common but very pleasing British species is *S. Filipendula* (Dropwort), which grows from one to two feet

Spiraea Aruncus.

high, and has yellowish-white flowers (often tipped with red) in loose terminal corymbs. The leaves of this plant are mostly radical, or on the lower part of the stem, and are pinnate, with oblong-linear deeply-toothed segments. When the flower-stems are pinched off, it forms a very effective edging-plant, the fern-like aspect of its foliage rendering it very distinct from many other plants which are used for this purpose. The double variety *S. Filipendula* fl. pl. will be found useful in the mixed border. It thrives in ordinary soil, and is multiplied by division of the tufts.

Perhaps the handsomest of the hardy *Spiræas* is the American species known as *S. venusta*. It grows from one and a half to three feet high, and has deep rosy-carmine flowers in large terminal compound cymes. The leaves are pinnate, with palmate-lobed leaflets, the lobes of which are pointed and irre-

gularly toothed. It does best in sandy loam, and is valuable for the mixed border or for planting on the margins of shrubberies, or in beds among groups of the finer perennials.

Another new and handsome kind, somewhat resembling the last-named, but dwarfier, is the Japanese species *S. palmata*, which grows from one and a half to two feet high, and has crimson flowers in a many-branched terminal panicle. The leaves are palmate in shape, with from five to seven smooth, veined, reticulated lobes. Suited for the same positions and soil as the last-named kind.

The common British Meadow-sweet (*S. Ulmaria*) would, no doubt, be considered a plant of high merit were it only an exotic. It is seldom seen in gardens, but there are often worse things to be found in our borders. As it is too well known to need any description here, we shall merely say that it deserves a place, if only for the sake of variety, in the mixed border, on the margins of shrubberies, or in the rougher parts of pleasure-grounds, where it may be advantageously planted with other subjects which do not require much looking after. Almost any soil will suit it; if moist, so much the better.

MR. PEARSON'S GERANIUMS.

BY QUINTIN READ, PLEASLEY, MANSFIELD.

It is well known that for many years Mr. Pearson, of Chilwell, has devoted unremitting attention to the raising of new Geraniums, and that neither money, nor labour, nor house room has been spared to accomplish his purpose. As an instance of the pains taken to enable him to arrive at a just estimate of their merits, I may mention that on his lawn, near his residence, I saw the other day no fewer than seventy circular beds, each planted with one separate sort in sufficient quantity to give a good mass of colour, and to test their adaptability for the flower garden. Besides these some four thousand seedlings have been planted out in his trial grounds, the result of crosses made by Mr. Pearson's own hands. A house one hundred feet long is also filled with such a glowing mass of dazzling beauty that I am afraid to attempt a description of it. All of us know how effective conservatories are during the Azalea and Camellia season, but even when at their best they could not surpass in brilliancy the rich varied tints of this house of Geraniums. Let us take them in separate colours, and in the first place we will begin with pinks.

In this class *Amaranth* possesses perhaps the deepest shade of blue of any Geranium yet in cultivation. It is a good bedding variety of the style and habit of *Christine*, with plain leaves, the truss compact, with a deep blue-tinted rose colour; altogether an excellent variety. *Rose Bradwardine* is also a valuable variety, which produces a profusion of lovely rosy pink flowers; its habit is compact and its trusses of bloom are very large. *Rose Peach* is a deep glowing pink, dwarf in habit, and highly attractive, altogether a most interesting variety. *Lady Louisa Egerton* is a bold pale pink with a light centre, truss very large, and the individual flowers also bold and conspicuous, habit good. *Mrs. Lowe* is another beautiful kind with a dwarf habit; it is half a *Nosegay*, and has a wonderfully fine truss; it will prove a valuable bedding variety, owing to its compact habit of growth, and the profusion of rich flowers which it produces. A bed of it in the trial grounds proved its adaptability for flower garden purposes. *Florence Durand* is a rosy pink with a deep shade of purple; we have it in bloom in our conservatory, and it stands pre-eminent as an indoor plant; its great substance of petal and freedom of bloom make it also equally good for outdoor embellishment. *Mrs. F. Burnaby*, a kind with a pretty shade of pink, produces fine large trusses, and flowers perfect in form and shape; it has a good compact habit, and is a most effective pot plant. *Amy Robsart*, dark pink, merging into the softest rose, has a fine habit and truss. The Hon. Mrs. Eden is a gem in its way. It is a half *Nosegay* with plain leaves and pink flowers shaded with violet; in habit it is dwarf and compact; a first-class bedding variety. These include most of the pinks already sent out.

Among scarlets the most useful both for conservatories and for the embellishment of the flower garden, is *Corsair*. It is a rich scarlet, of perfect form, and so prolific in bloom, so fine in habit, substance, and truss, and so wonderfully good in all

respects, that Lord Derby and all others of that class are completely put in the background. Mrs. Hetley is a fine bold scarlet with a very large truss, and succeeds well out-of-doors; it is certainly one of the best either for in or outdoor purposes. Chunder Sen belongs to the same class of bright fiery scarlets, though more dwarf in habit; I think it will be an acquisition for outdoor decoration. Lord Belper, dark scarlet shaded with crimson, has a very large truss, and is one of the best for bedding purposes. Miss Stubbs, Mrs. Sibray, and Miss Sanders are all fine dark crimson flowers, with hold trusses and good habit. Thomas Adams is a finely shaped flower, red, shaded with salmon; also Charles Burrows, which is much in the same way, only a deeper red. Col. Holden is a rich rosy crimson, of faultless shape, good in substance, truss, and habit. Rev. T. F. Fenn, Mary Flower, Smeaton, and Samuel Bennett, have rich deep crimson well-shaped flowers and large trusses. These are all desirable varieties. Mrs. Hole is also a useful introduction, with deep magenta flowers; in habit it resembles Violet Hill Nosegay. Then come three other varieties, viz., Mrs. Vincent Fenn, Red Dwarf, and Shakespeare. These are likely to prove the most useful of all others for bedding purposes; all of them have the habit and freedom of bloom of Violet Hill with a deeper dash of scarlet in their flowers, a circumstance which greatly enhances their beauty. Violet Hill, though one of the very best of all bedding Geraniums, looks pale by the side of the three last named sorts.

Among golden tricolors Mrs. Docksey is one of the brightest and most attractive I have ever seen; Lady Manvers is also good, the colours being bright and pure; even Mrs. Pollock growing near it looked inferior to it. Wm. Sandy is one of Mr. Pearson's best tricolors. I had it growing in a pit during the spring months mixed up with other sorts, and it was always picked out as the best tricolor we had, even by the uninitiated. There were others in this class, all superior kinds, such as Abram Bass, Miss Locker, and Monsieur Durand, but the above are considered to be the best.

In the silver variegated section Pearl is an old favourite; it has a broad pure white leaf margin, with dark zone, and the flowers, a pretty shade of pink, contrast beautifully with the foliage. While on the silver-edged section I may mention three gems which will not be sent out for want of stock for some time to come, viz., Mrs. Bishop, Mrs. Wm. Hollins, and Miss Minna Hollins. These are more perfect and free from fault than anything I have ever met with in their way, and there is such a sweetness and softness in the flowers, and such chasteness in the foliage, that both flowers and foliage contribute to set each other off to advantage; Mrs. Bishop has lilac pink flowers, and Miss Minna Hollins soft delicate pink.

I must now advert to a few zonales that will be sent out next season. Some of them were planted out in the trial grounds in a mass, so that there was every chance of testing them both for outdoor and for indoor purposes. Rosinia May is excellent in the open garden; a splendid shade of pink, with a fine bold truss. Contessa Quarto is bright and beautiful, with dark pink trusses of bloom. Mrs. Holden and Mrs. Miles are also very good, with fine pink flower trusses. Matilda appeared to be one of the best for conservatory decoration; it resembles a finely-grown Hydrangea, for I noticed on a small plant in a small pot seven or eight trusses of bloom of immense size. Mrs. A. Bass is darker than some in this section; but among this class of Geraniums Mrs. Musters is the finest and best. I was curious enough to measure one truss of this sort, and I found it nearly seven inches across. Mrs. Young and Miss Skipworth, however, are also without a fault, the trusses being fine and symmetrical, but not so large as those of Mrs. Musters.

These varieties of Geranium are all of sterling merit. I cannot close my remarks without adding that the pot Vines at Chilwell are in excellent health; in a large house of seedling Vines were several that promised to reward Mr. Pearson for his care and labour bestowed in that direction. The fruit trees in the orchard houses were a great success, and whether in pots or planted out they were loaded with fine fruit. I was delighted with the system of growing Figs in pots plunged in the open border; the trees are vigorous and healthy and covered with an abundance of large fine Figs. La Madeleine is among the best and earliest Figs in the collection.

HERBACEOUS PLANTS.

A SUGGESTION RESPECTING THEM.

TRIAL by jury is one of the most distinct features of our legal code. Without question it has merits of a very high order, and, in comparison with the single judge system, its findings are, in a large majority of instances, much more satisfactory. Indeed, in a plain case, with twelve good men and true, their finding is as near perfection as it is possible to get it. Aware of this fact, editors of horticultural papers, instead of pronouncing "judgmentally" on every occasion on which their advice is asked, have, for some time, pressed the good old English jury system into the service, and now, if you ask them to hand you the names of the best twelve Pears, six Cabbages, three Onions, twelve Peaches, three Cucumbers, or whatever it may be, you do not get the usual editorial dictum, but you get the result of the last jury trial, when some twenty of the best gardeners in the country gave their practical opinion on the several merits of the various fruits and vegetables grown in our gardens. Now, my suggestion is, could not you shift the jury (or empanel a new one) on to the herbaceous department, and get their candid and well-weighed opinion as to the best flowering one hundred, fifty, or twelve sorts for the border; then the same in regard to foliage plants; then say the best fifty, twelve, or six for exhibition; then you might put the hardy shrubs, both flowering and foliage kinds, in the "dock;" and, if time permitted, even the stove and greenhouse plants might also be overtaken. To ensure accuracy, nurserymen and gardeners might both give their awards, which might be separately published. The above would be sure to clear away much of the mist that at present hangs over the best in these sections, particularly the herbaceous, and would certainly be an admirable guide for amateurs and others who desire to buy, and nurserymen who require to propagate such things. It would also save the former much more than useless expense in acquiring, and the latter in propagating, the mass of rubbishy plants that constantly obscure the merits of the section, and the many most truly deserving subjects to be found in it. I therefore trust you will give effect to the suggestion which I have just made.

W. W.

[We shall be very glad to do so, and, now that most kinds of herbaceous plants are in full beauty, hope to receive from different quarters lists of such kinds as are found to give the greatest satisfaction, both in point of ornamental effect and duration of bloom.]

GLADIOLI.

ENGLISH *v.* FRENCH SEEDLINGS.

At the Devon and Exeter Flower Show, which took place the other day, Messrs. Kelway & Sons, of Langport, exhibited a stand of seedling Gladioli, which surpassed anything I have ever seen. Near them were some continental seedlings of the same flower, which could not be compared with those of Messrs. Kelway. Knowing how many growers think that no English seedlings are to be compared with those we receive from abroad, I think it may interest some of your readers to know that this is not always so. I subjoin a list of the seedlings exhibited by Messrs. Kelway, naming those to which first-class certificates were awarded.

* Batavus—crimson and marone, violet stripe on lower divisions.

Larina—purple crimson, large white blotch on each petal.

Rosea alba—white, with rose blotches.

* Maria—pure white, lilac blotch on lower divisions.

Yellow King—pale yellow, flaked with lake.

* Ustica—white flaked lilac.

* Adrius—scarlet crimson flaked marone.

* Artacia—salmon rose flaked crimson.

Garnet—rose flaked purple.

Adela—white yellow, with violet stripe on lower divisions.

Those marked with an asterisk (*) are those to which first-class certificates were awarded. JOHN B. M. CAMM.

[The following are the names of the thirty-six sorts with which Messrs. Kelway won the silver cup as first prize at Dublin last week:—

* Ate—crimson flaked marone, large white centre.

Antigone—tender rose, largely flushed with carminate red.

Distinction—orange rose flaked carmine, purple centre.

Sesia—white flaked rose, yellow centre.

Eva—pale lilac flaked purple, large purple centre.

Abula—rosy red, white centre, purple on lower divisions.

Homerus—white, lilac centre.

Miss Warren—cerise white throat, violet on lower divisions.

Battus—light rose, lilac on lower divisions.

Rossini—dark amaranth red, livid, and stained with white.

A. Brongniart—rose ground, slightly tinged with orange, flushed with red, large white stain.

Amelia—lilac purple, large ivory centre.

Augens—cerise flaked lake, large ivory centre.
 Horsa—dark salmon veined marone, purple on lower divisions.
 *Ball of Fire—brilliant scarlet, black on lower divisions.
 Ababa—cerise, large white centre.
 Orphe—rose, flushed with carmine, fine stain of carminate purple on lower divisions.
 Albia—salmon flamed carmine, purple on lower divisions.
 Amor—large cerise, white centre, veined purple.
 *Egyptian King—marone flaked crimson, white centre, violet stripe.
 Alice—white, yellow centre, violet striped.
 Brutus—mauve, flaked purple, orange centre.
 Melud—salmon, purple on lower divisions.
 Mrs. Reynolds—white, flaked lilac.
 Veronica—white, tinged lilac, violet on lower divisions.
 Rutuba—red, blue centre.
 Hesperia—orange scarlet, lilac on lower divisions.
 Ophelia—red, flaked carmine, violet centre.
 Cleonica—plum, flaked purple, yellow on lower divisions.
 Herbert—scarlet, white centre.
 Accua—white, flaked purple, violet striped.
 Leonica—dark crimson, violet striped.
 Baltia—cerise, flaked scarlet, orange centre.
 Tetrica—salmon rose, purple on lower divisions.
 Shakespeare—white, slightly flushed with carminate rose.
 Peronia—fine rose, carmine on lower divisions.
 In the class of twenty-four sorts the first prize was awarded to the following :—
 Candia—blush flaked carmine, yellow centre.
 Velia—mauve, white centre, white line on each petal.
 Abazea—crimson flaked black, large ivory centre.
 Madame Desportes, pure white, slightly striped with violet on lower divisions.
 Mr. Glasecock—lilac flaked purple, lilac on lower divisions.
 Batavus—carmine flaked marone, violet stripe on lower divisions.
 Uramia—pure white, largely flushed with carminate bright rose.
 Hortensia—rose veined purple on lower divisions.
 *Beauty of England—pure white, yellow blotch on lower divisions.
 Clupea—white, lightly flaked rose.
 Voluba—ivory-white, orange centre, flaked purple.
 Adolphe Brongniart—rose ground, slightly tinged with orange, flushed with red, large white stain.
 Cillaha—flesh, feathered red, purple on lower divisions.
 Madame de Vetry—white, slightly sulphurish, stained with purplish carmine.
 Orphe—rose, flushed with carmine, fine stain of carminate purple on lower divisions.
 Olbia—purple rose, white blotch on lower divisions, violet throat.
 Ustica—white, slightly flaked lilac, striped with rose on lower divisions.
 Herbita—scarlet, large yellow centre, carmine stripe.
 Corduba—white, purple on lower divisions.
 Le Gouver—bright red, white line in the centre of superior divisions, white spots on the lower divisions.
 Julia—pink, flaked rosy crimson, purple throat.
 Abrota—white, lilac on lower divisions.
 Ancyra—sulphur.
 Parsonii—flesh, flaked red, purple centre.
 To the following twelve a first prize was also awarded at the same exhibition :—
 Prince Arthur—white, flaked lilac purple, large carmine centre.
 Tribune—lilac rose, purple on lower divisions, flaked red.
 A. Brongniart—rose ground, slightly tinged with orange, flushed with red, large white stain.
 Anaphi—white flamed rose, lilac on lower divisions.
 Hecuba—crimson, violet centre.
 Sophia—light plum, flaked purple on lower divisions.
 Orphe—rose flushed with carmine, fine stains of carminate purple on lower divisions.
 Rossini—dark amaranth red, lined and stained with white.
 *Miss Phillis Stuckey—salmon flaked carmine, light centre.
 Elisa—salmon rose, purple on lower divisions.
 Shakespeare—white, slightly flushed with carminate rose.
 Brennus—crimson flaked marone, white centre, purple stripe.

Ugly Examples of Bedding Out.—A friend of ours is collecting illustrations of bad examples of bedding, and will be glad to receive any sketch or plan, no matter how rudely coloured, showing hideous designs. He proposes publishing a small illustrated work on the subject.

Dahlia coccinea.—Two years ago Sir Charles Isham gave me a root of this very beautiful tuberous perennial. It was a dwarf mass of brilliant scarlet bloom all last summer, and one of the gems of the garden. I grieve to say that my tubers all rotted last winter. Sir C. Isham has also, he tells me, lost it. Can any one replace my loss? for it is one I feel much.—H. H. CREWE, *The Rectory, Drayton-Beauchamp, Tring.*

Orisia coccinea.—At Messrs. Rollissons, at Tooting, this fine plant is found to luxuriate under the treatment given to ordinary alpine plants; plants of it stood outdoors the whole of last winter plunged in sand, and this season they have grown and flowered as well as those that were wintered in a cold frame. The soil used for them is about two-thirds mellow loam, the remaining portion being well decomposed leaf mould and some sharp sand. I have not noticed this plant at any other of our London nurseries; will any of your readers favour me with their experience in regard to its culture, and also as to its hardiness?—ALPHA.

THE FRUIT GARDEN.

THE NORTH AMERICAN VINES.

BY CHARLES V. RILEY, ENTOMOLOGIST TO STATE OF MISSOURI.

In few genera of plants is it more necessary to accumulate abundant material in order to arrive at correct classification than in the genus *Vitis*. The species are with difficulty defined, as they vary in a marked manner in different sections of the country, and the foliage of the same individual vine often varies greatly at different ages and seasons. Preserved leaves are not alone to be trusted to therefore, but every stage of growth must be considered, from the wood to the different leaves, the blossom, bunch, berry, and even the seed, which, in its shape, and especially in the development of its raphe (or cord) furnishes, according to Dr. Engelmann, some of the most permanent distinguishing traits between the species.

It is interesting to know that not a single real species has been added to those belonging to the old territory of the United States, east of the Mississippi river, since the time of Linnaeus and Michaux; though Rafinesque, Le Conte, and perhaps others, have attempted to distinguish a great many more.

The number of Grape vines bearing edible fruit, now considered species by the best botanists, in the territory of the United States is limited to nine. They may be tabulated as follows :—

I. Vines which are of practical importance, as having yielded our different cultivated varieties :—

1. *Vitis Labrusca*, Linn. Northern Fox.
2. „ *estivalis*, Michx. Summer Grape.
3. „ *riparia*, Michx. River Bank Grape.
4. „ *vulpina*, Linn. Southern Fox, or Muscadine.

II. Vines of less importance, and which have thus far given no cultivated varieties :—

5. *Vitis cordifolia*, Michx. Winter, or Frost Grape.
6. „ *Californica*, Benth. Confined to California.
7. „ *Arizonica*, Engelm. Similar to the last.
8. „ *caudicans*, Engelm. Mustang Grape of Texas.
9. „ *rupestris*, Scheele. Bush Grape or Sand Grape.

Of these nine species, only four grow wild in our own State, viz., *estivalis*, *cordifolia*, *riparia*, and *rupestris*.

In stating last year that our cultivated varieties had been referred to four species, including *cordifolia*, and omitting *riparia*, I followed the later editions of "Gray's Manual," in which the latter is considered as a variety of the former. The reasons for adopting a different course will be found in the following synopsis, which has been kindly prepared for me by the author :—

THE TRUE GRAPE VINES OF THE OLD UNITED STATES.

BY DR. GEORGE ENGELMANN, OF ST. LOUIS.

I. Grape-vines with loose bark (at last separating in shreds), climbing by the aid of branched tendrils, or (in No. 4) scarcely climbing at all.

a. Berries small, 3 to 6 or rarely 7 lines in diameter; seeds obtuse, with the raphe (or cord) more or less prominent (except in No. 4) over the top. All the species of this group, just like the European Grape-vine, exhibit, on well-grown shoots, a regular alternation of two leaves, each having a tendril (or its equivalent, an inflorescence) opposite them, and a third leaf without such a tendril.

1. *Vitis cordifolia*, Michaux.—Usually tall, climbing high, trunks not rarely 6 to 9 inches in diameter. Leaves middle-sized, heart-shaped, mostly entire or rarely slightly trilobed, with shallow broad teeth, usually smooth and shining on both sides, the young ones sometimes slightly downy below; berries among the smallest, in large bunches, black without a bloom, maturing late in the fall, usually with only one short and broad seed marked by a prominent raphe. This is a common plant, especially in the river bottoms, and is known under the name of Winter Grape, Frost Grape, or Chicken Grape. It is found from New England to Texas, and westward to the western limits of the wooded part of the Mississippi valley. In this valley at least, the fruit has a strongly and even fetidly aromatic taste. No cultivated varieties of the species are known.

2. *Vitis riparia*, Michaux.—Mostly a smaller plant than the last, but with larger and more or less cut-lobed glabrous shining (or rarely, when young, slightly downy) leaves, the lobes long and pointed; the teeth also more pointed than in *cordifolia*; berries as small as, or usually larger than in the last, mostly with a bloom, in smaller bunches, mostly one or two seeded; seeds with a less prominent raphe. This prefers thickets or rocky soil on river banks, and extends as far west and south as the last, and much farther north, being the only Grape-vine in Lower Canada, where it is found even sixty miles north of Quebec. The northern form, in Canada, Northern New York to Michigan, and Nebraska, has fewer and larger berries in a bunch, and is easily distinguished from *V. cordifolia*

The south-western form, however, approaches more closely to this last species, with which Professor Gray, in the later editions of his "Manual," has united it. The fruit ripens earlier than that of *cordifolia*, and is much pleasanter. In St. Louis a variety found on the rocky river banks is brought to market in July. A number of cultivated varieties are referable to this species, among which the Taylor Bult, the Delaware, and the Clinton are the most prominent.

3. *Vitis æstivalis*, Michaux.—Smaller than the first, climbing over bushes and smaller trees; leaves large, of firmer texture than the preceding ones, entire, or often more or less deeply and obtusely 3 to 5 lobed, with short and shallow broad teeth, when young always very woolly, mostly bright red or rusty, at last smoothish, but dull, and never shining like the preceding ones; berries usually larger than in both the others, and, when well grown, in compact bunches, coated with a distinct bloom; seeds usually two or three, with a very prominent raphe. This is the summer grape common throughout the middle and southern States, usually found on uplands and in dry open woods or thickets, maturing its fruit in September. It is the most variable of our grape-vines, and hence has seduced superficial observers into the establishment of numerous nominal species. A form with large leaves which retain their rusty down at full maturity has often been mistaken for *Labrusca*, which does not grow in our State. Another form, more bushy than climbing, with deeply lobed rusty-downy leaves and very sweet fruit, is *Vitis Liucecumii* of the sandy soil of Louisiana and Texas. This species assumes a peculiar form approaching *V. cordifolia* through its smaller black berries without bloom and in larger bunches, when it gets into shady woods with rich soil. Another form with ashy-white, downy, scarcely lobed leaves, and fruit like the last mentioned, which grows in our bottoms, often climbing high trees, or growing over bushes on the banks of lakes, I have distinguished by the name of *cinerea*. It is not always easy to distinguish such forms from the other species, and perhaps less so to unite them under the single species *æstivalis*, unless the essential characters above enumerated be closely attended to, and the numberless gradual transitions from one form into the other be watched. We cultivate many varieties of this valuable species, the most important of which are the Virginia Seedling, the Cynthiana, and the Herbmont.

4. *Vitis rupestris*, Scheele.—A small bushy plant, often without any tendrils, rarely somewhat climbing; leaves small (2 to 3 inches wide) mostly broader than long, heart-shaped, scarcely ever slightly lobed, with broad coarse teeth, and usually an abruptly elongated point, glabrous, and of a rather light green colour; berries middle-sized, in very small bunches; seeds mostly 3 to 4, obtuse, with a very delicate raphe. This Grape-vine is found only west of the Mississippi, from the Missouri river to Texas, and westward probably to New Mexico. In our State, where it is called Sand Grape, and in Arkansas, it grows on the gravelly banks and over-flowed bars of mountain streams; in Texas also, on rocky plains, whence the Latin name; it is there also known under the name of Sngar Grape. Its luscious fruit ripens with us in August. It is nowhere yet in cultivation, but may in future prove of value.

b. Berries large, 7 to 9, or even 10 lines in diameter; raphe scarcely visible on the more or less deeply notched top of the seed. These plants, on well-grown shoots, bear a tendril opposite each leaf, with only rare and irregular intermissions.

5. *Vitis Labrusca*, Linnæus.—Plants usually not large, climbing over bushes or small trees, though occasionally reaching the tops of the highest trees, with large (4 to 6 inches wide) and thick, entire or sometimes deeply lobed, very slightly dentate leaves, coated, when young, with a thick rusty, or sometimes whitish, wool or down, which, in the wild plant, remains on the lower side, but almost disappears in the mature leaf of some cultivated varieties; berries large, in rather small or middle-sized bunches, bearing two or three, or sometimes, four seeds. Known as the Fox-grape or Northern Fox-grape, it is a native of the eastern slope of the continent from New England to South Carolina, where it prefers wet thickets; it extends into the Alleghany Mountains, and here and there even down their western declivity, but is a stranger to the Mississippi Valley. The most important varieties of this Grape-vine now cultivated in our country (such as the Catawba, Concord, Isabella, Hartford Prolific, and dozens of others), are the offspring of this species; they are all easily recognised by the characters above given, and more readily by the peculiar arrangement of the tendrils as above described.

II. Grape-vines with a firmly adhering bark, which does not scale off; tendrils almost always simple; berries very large (7 to 10 lines in diameter), very few in a bunch; seeds with transverse wrinkles or shallow grooves on both sides.

6. *Vitis vulpina*, Linnæus.—Bushy, or sometimes climbing high, with small (two or at most three inches wide) rounded, heart-shaped, firm and glossy dark-green leaves, smooth or rarely slightly hairy on the under side, with coarse, large or shallow teeth. This southern

species, known under the name of Southern Fox-grape, Bullace, or Bullet-grape, is found along water-courses, not further north than North Carolina and Arkansas, and may possibly straggle into south-eastern Missouri. Some of its cultivated varieties, especially the white Scupper-nong, are highly esteemed in the South but do not perfect fruit in the latitude of St. Louis.

I recognize only three other species of true grape-vine in the territories of the United States. The most remarkable of these is the Mustang grape of Texas, *Vitis candicans*, Engelm. (*V. Mustangensis*, Buckley), with rather large, rounded, almost toothless, rarely deeply-lobed leaves, white and woolly on the under side, bearing large berries, which in its native country are now beginning to be made into wine. *Vitis californica*, Benth., the only wild grape of California, has rounded downy leaves, and small berries, and is not made use of as far as known. *Vitis Arizonica*, Engelm., similar to the last, but glabrous, with middle-sized berries, reported to be of a luscious taste. None of these show a prominent raphe on the seed, so that this character is peculiar only to the first three species here enumerated.

OUR FRUIT CROPS.

Petworth House, Sussex.—Apricots here are a complete failure. Peaches and Nectarines are thin, and trees much injured by late frost. Apples are a very deficient crop. Pears, good, particularly on some young pyramidal trained trees. Plums, none on wall trees, standards thin, but we have a good crop of Damsons. Morello Cherries are a moderate crop, others a failure. Gooseberries have been a good crop. Currants, red and white, half a crop, fruit small; black, good, and the trees are clean and healthy. Raspberries have been a good crop. Strawberries, an average crop. Filberts and Cobnuts, partial; Walnuts, none.—T. JONES.

Wilton House, Salisbury, Wiltshire.—Apples are a complete failure, probably caused by the unripened state of the wood in the previous autumn, owing to the great quantity of rain which fell at that season and during the winter. Apricots, a very poor crop, even where protected by blinds. Cherries, a failure, except on walls, on which there was a partial crop. Currants, partial crop; in wet localities quite a failure. Figs, a poor crop. Gooseberries, a partial crop. Nuts, a fair crop. Peaches and Nectarines, none, only where well protected. Pears, quite a failure, except in elevated positions. Plums, very poor. Raspberries and Strawberries, good. Walnuts, none; young shoots killed back 3 or 4 feet.—T. CHALLIS.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Western Triumph Blackberry.—This new kind is highly spoken of in America. It is very hardy, as good in quality as such older kinds as the Lawton or Wilson, and said to possess a peculiarly rich flavour. Will none of our growers of small fruit see what is the value of these Blackberries in our climate? In America, as we can testify, they are really valuable fruits, as far before the Blackberry known to us as the Ribston Pippin is before a common cider Apple.

How Wine is coloured.—The following pleasant news for wine connoisseurs is contained in a letter from Carlsruhe:—"Just as usual, several cartloads of bilberries are passing through our city en route for Wurtemberg, where they will undergo a process of pressing and be sold to the wine dealers for colouring wines, &c. Many a wine-drinker thinks while he quaffs his red wine, that its tint has been derived from the glowing sun of Bordeaux or the upper Rhine, whereas, in reality, it is indebted for it to the Pine forests of the 'Odenwald.'"

Our Fruit Crops.—I notice two curious peculiarities in reference to these viz.: the unusual quantity of Apples that fall off prematurely this season, and the early maturity of several sorts of fruits—Pears, Plums, Apples, and even the few Peaches that have been left on walls seem to ripen sooner than usual. As to the falling off of unripe fruit, most people would attribute it to spring frosts; but if so, why do not the Pears, which suffered as much or more, not fall off likewise? The premature ripeness is also singular, as upon the whole we have had but little sun.—D. T. FISHER.

Criminal Carelessness.—A gentleman's son was drowned the other day at Sandhurst, Berks, in his father's garden. The unfortunate boy was named Roderick Campbell Johnson, son of Mr. Alexander Robert Campbell Johnson, of Heatherley House, Sandhurst. The inquest was held at Heatherley House, where it transpired that the deceased, who was scarcely six years of age, was in the garden playing with the flowers, under the charge of the head nurse. There was a pond in the garden totally unprotected, and when the woman looked for the child, about one o'clock, to give him his dinner, she could not find him. Captain Palliser, R.N., who was staying at Heatherley House, also went in search of the lad, hearing he was missing. He went to the pond and found the child in it, and pulled it out to all appearance dead. The child was put in a warm bath, and efforts made to restore animation, but without avail.

GARDEN DESTROYERS.

LIPARIS SALICIS—THE SATIN MOTH.

THE passer-by who strolls along any of our country lanes within reach of willows or poplars in the months of July and August, especially if, like an entomologist, he disturbs the foliage of the trees and hedges, may now and then see something white dart out, flit away, and disappear again among the leaves. It is obviously a moth or butterfly, almost as large as the white cabbage butterfly, but he at once sees that it cannot be it. It is far too white, too snowy, too downy. The cabbage butterfly flutters about and lirts from spot to spot, not hurrying out of sight. No doubt its motions are inaudible to us, but they do not look so. They do not suggest the idea of stillness and silence; the insect of which we speak, and which is figured above, does. It reminds one by its purity, its softness, and its impalpable style of motion, of the fall of a flake of snow. The ghost moth is nearly as white, but it floats stationary in the air instead of imperceptibly thawing away out of sight amongst the leaves. Nothing that we have met with has so completely this effect as our present subject and one or two of its allies.

It is a moth called *Liparis salicis* (the Willow *Liparis* or

Satin moth, which latter colloquial name happily expresses its most prominent character). It is pure snowy white, without spot or speckle, and clothed with most delicate silky hair; the body is black, but being also covered with long silky white hairs, appears white like the wings. The antennæ alone form a contrast, for they have short black rays.

The caterpillar is hairy and gaily coloured. It has two black stripes spotted with red tubercles down the sides and along the middle of the back; between the stripes is a snow-white or citron-yellow space or series of spots. The sides are grey, with red tubercles. The hairs with which it is clothed are golden yellow.

The chrysalis is very hairy, and lies in a web spun on the trunks of trees or on the ground. The perfect insects appear in July or August, and sometimes are in such numbers as to mimic a snowstorm by the males flying from one tree to another. The female lays from one hundred and fifty to two hundred eggs in patches on the bark or leaves of the tree. These are not left bare, but are covered by a crust, like a patch of frozen spittle. The eggs are pale grey. The caterpillars are hatched in about a fortnight or three weeks. They do not go into the pupa state until the next year, passing the winter in crevices of the bark and under moss, &c. As is implied by its name, the caterpillar feeds on the leaves of the willow or poplar, although it may not absolutely confine itself to them. It is common in England, and generally throughout Europe, and trees may occasionally be seen presenting the melancholy aspect of winter in summer, being wholly deprived of their foliage by it; and young and weak trees are often killed by it. The caterpillars are very voracious, and clear off the whole leaf, leaving nothing but the stalk and mid-rib.

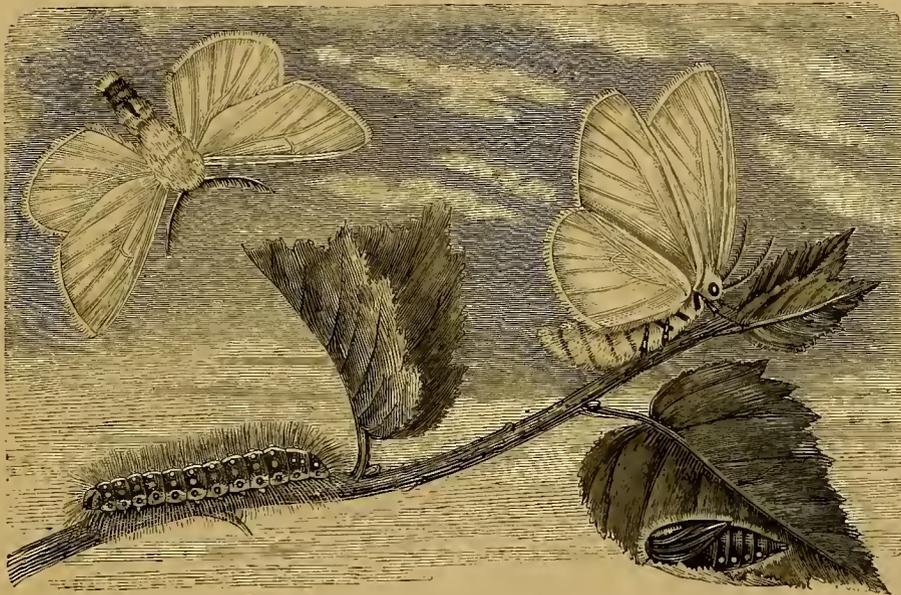

The best mode of dealing with this species is to attack it in

the egg stage. The hard glossy deposit of apparently frozen spittle which covers the eggs can be so easily detected by anyone who has once had it pointed out, and is so easily removed, that it is not difficult to destroy great numbers with small trouble. The patch of eggs is about the size of a shilling, or a little larger, and if it is on the bark, a slice of that part on which it rests can be cut off; if on a leaf the leaf can be pulled. Both sides of the leaves must be looked at, as it does not confine itself to one side. By this means a man may (according to Kollar) examine a whole avenue in one day and destroy many thousand eggs. The great thing, however, is to see that the eggs are really destroyed. If they are only thrown on the ground they might as well have been left alone; all the trouble of gathering them is thrown away.

The gravid female moths may also be sought for on the trunks of the trees in August. Their colour easily betrays them, and being heavy and disinclined for motion, they prefer to sit still on the bark, and are easily caught. Many of the hibernating caterpillars also may be destroyed during the winter by examining the trees they frequent. They are said not to be so much exposed to the attacks of parasites as other caterpillars, which, if true, may perhaps be due to their hair-

ness rendering it more difficult for the ichneumonous to deposit their eggs in them.

A. M.

The Satin Moth. (*Liparis salicis*.)

ness rendering it more difficult for the ichneumonous to deposit their eggs in them.

Economic Entomology.—We are informed that prizes for collections of economic entomology are offered for competition in 1873, and the following rules relating thereto have been issued by the Royal Horticultural Society:—£10 for a collection of British insects injurious to some one order of plant used for food—as Cruciferae, Leguminosae, or corn; the order may be selected by the competitor. £3 for a miscellaneous collection of British insects injurious to plants used as food. £5 for a collection of British beetles injurious to timber and fruit trees, either growing or felled. £2 for a collection of British insects injurious to some one timber or fruit tree. The insects to be exhibited in their various stages of development, accompanied by specimens, models, or drawings of the injuries caused by them. The collections to be sent in addressed to James Richards, Assistant Secretary, Royal Horticultural Society, South Kensington, S.W., on or before November 1st, 1873.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

To Destroy Ants.—Fill small phials two-thirds with water, and add sweet oil to float on the water to within half an inch of the top. Plunge these upright in the ground, leaving only half an inch standing out, near the nest or runs of the ants. The ants will come for a sip, and go home to die. No insect can exist with oil stopping up its spiracles or breathing pores.

To Destroy Black Beetles.—A certain remedy is to procure some bracken, *Pteris aquilina*, or common fern, plentiful on commons, and put it down about the house at night. The black beetles will eat it ravenously and soon die, and their relatives will pick their bones. It is commonly used in the north of England.—*English Mechanic*.

Caterpillars on Cabbages.—One of my friends, a landed proprietor in the Ardennes, informs me that, one day, having observed in the garden of a peasant that the cabbages were covered with froods of the common bracken (*Pteris aquilina*), he inquired the reason, and was told by the owner that it was a certain and easy way to get rid of the caterpillars. My friend made a trial of the remedy himself, and he assures me that in one hour after the bracken-froods were laid on, not a caterpillar was to be seen. Elder leaves are said to be equally efficacious.—E. M., "*Belgique Horticole*."

THE INDOOR GARDEN.

TRITONIA AUREA.

At present this is one of our prettiest conservatory plants, and its easy culture and free-blooming qualities should gain for it a wider range of cultivation than it has hitherto had. It belongs to the Iris family, is nearly allied to the *Ixias*, and has half tuberous roots, by means of which it is readily increased. It requires but little cultural care, for it is very tenacious of life, and will stand the winter if kept dry and covered over with a little straw in a shed or cellar. I once grew a great many for conservatory decoration in July and August, and well did they serve as associates to the Japan Lilies, Balsams, and fine-foliaged plants which play the most prominent part at this season.

In our gardens was a large glass house open at one gable end, which was considered the front, the sides being made of upright deals, each about a fourth of an inch distant from the other, so that although a valuable house for placing flowering plants in in the summer and autumn, it was of no use in this way in the winter months. Throughout the cold winter months, however, we stored in it ladders, garden seats, frame sashes, &c., and amongst other plants the *Tritonias*. These I stored away in a corner, covering the pots with some leaves or litter, so as to prevent the frost touching the roots, for our winters were commonly very severe. In this position they remained untouched till the end of February, receiving no water whatever during that time, yet the soil never became too dry. I then took them into the greenhouse, gave them a little water, and, as soon as time permitted, repotted them, using a compost of three parts good yellow loam, one of rotten manure or leaf-mould, with a good admixture of sharp river sand and finely broken crocks. In potting, I took particular care to have good drainage, and in turning out the plants, to preserve the roots from mutilation. If I wanted to increase my stock, I took off as many joints of the rhizomes as I thought convenient, and potted them. I also found it necessary to reduce the size of the plants sometimes, for unless that is done they get too big for suitable pots, and placing them in pots larger than ten or at most twelve inches in diameter gives them a clumsy appearance, and if their roots are too confined they come up spindly, and the leaves assume a yellow tinge in the autumn sooner than they otherwise would. After potting, I place the pots on stages in an airy house near the glass, in company with the Japan Lilies; I keep them just moderately moist at the first, but as they advance in growth I give them good soakings, and when they are throwing up their flower spikes I find they are greatly benefited by occasional applications of manure water. They need no further care throughout the summer than the support of a neat stake or two at the flowering season. They continue a long time in bloom, and as soon as their beauty begins to fade I cut over the flower spikes about half way down, but allow their base and all the leaves to remain untouched until they naturally decay, when I cut them over a few inches above the pot, and keep the plants a little drier than formerly. As soon as frost was likely to set in, I stored them away in their winter quarters, and treated them as before. The fleshy rhizomes, should the soil become too dry in the winter, are apt to get damaged, but when covered with leaves or litter such is unlikely to take place.

CLEMATISES.

It may not be out of place here to say that in the house above referred to the finer kinds of hybrid Clematises are grown, planted in the borders and trained across the roof. There is no protection whatever given to them in the winter, further than a good mass of litter around the roots, but not touching the stem. In this position they thrive remarkably well, and although in winter often subjected for a week together to 20° of frost, burst forth in spring with surprising vigour. The leaves are never removed until the buds begin to break, then when the dead wood can be distinguished from the living, the leaves and all inanimate portions are cut away. It is also often found necessary to remove a good many of the living shoots, to prevent overcrowding.

This is a beautiful house in the summer, in fact the Clematises

produce such a profusion of bloom that it is almost a pity to have other good plants under them, and unless the dropping flower-leaves are carefully removed every morning, they would certainly be very detrimental to the other plants. All the finer kinds raised prior to six years ago are planted in this house, and most glorious amongst them stands *C. lanuginosa*. The greatest enemy in our northern climate to Clematises and other plants in winter is dampness at the root, and where that can be guarded against, it is surprising what can be kept alive, even through our hardest winters. Beneath each of the Clematises I had a barrowful of rough stones placed and covered over with turf, so that there was no fear of water lying about their roots. In summer, however, the amount of water they get is enormous; but the more they get the stronger they grow, and, consequently, there is the greater need for pruning, tying, and regulating. WM. FALCONER.

TREE FERNS.

WHAT has contributed more to the embellishment of our conservatories, and taken away the monotony which used to prevail in the good old times (when a mass of gaudy flowers, arranged on a stage so as to show the pots well, or set in rows on the beds, was the *beau idéal* of gardeners), than these graceful inhabitants of the damp ravines of Australia, the Cape of Good Hope, and the West Indies? What is more beautiful than a fine *Dicksonia antarctica*, *Cyathea dealbata*, &c., for the centre of a conservatory? or two planted so as to form an arch over a walk leading from that part of the house set apart for flowering-plants to the cool and charming spot where delicate ferns soften the scene and charm the fancy? Most people love ferns, and wish to have representatives of their various modes of growth, but as many do not know what species are best suited for this purpose, I shall name a few of the best, both for greenhouse and stove cultivation.

STOVE OR WARM CONSERVATORY.

CYATHEA ARBOREA (WEST INDIES).—A very distinct and handsome tree fern, of tall and rapid growth, from ten to thirty feet high. It forms a splendid crown of pale-green, gracefully-spreading fronds, from six to twelve feet long, the midrib of which, as well as the stem itself, is densely covered with large white chaffy scales and hairs.

CYATHEA EXCELSA (MAURITIUS).—This is not such a large or rapidly-growing species as the last, its height ranging from twelve to twenty feet. The fronds are tripinnate, of a very dark-green colour, and form a very beautiful, somewhat arching crown. It requires stove heat.—Syn. *C. Cooperii*.

CYATHEA PRINCEPS (MEXICO).—For those who have a space of twenty feet to spare, no nobler fern can be selected than this. It grows rapidly and forms a stout stem, which, as well as the crown of the plant, and the midrib of the fronds, is densely covered with large, light-brown, or white chaffy scales and hairs, which impart a soft, silky appearance. The fronds are tripinnate, of a bright light-green colour, from three to twelve feet in length, and form a beautiful arching crown. This species may also be grown in the cool conservatory.

CIBOTIUM SCHIEDII (MEXICO).—A very elegant and free-growing species, with large, spreading, pendulous, pale-green fronds, from six to fifteen feet long, and rather irregularly disposed. The stem, crown, and midrib of the fronds are densely clothed with long, silky, chestnut-coloured hairs. Planted in a prominent position on a rockwork, in a large house, it presents a very imposing appearance. It may also be grown in the cool conservatory.

The soil best suited for these large tree ferns is turfy loam. The common practice is to use peat, but I have noticed that many imported plants had been taken out of loam, and, in some instances, out of clay. Any one who has seen a well-arranged house, with here and there a tree fern, will never be content without them; but they should not be associated with brick walls, as the ferns make the walls look barbarous, and the walls cause the ferns to look out of place. Many of the *Davallias* and *Polypodiums* may be grown on their stems, thus bidding their bareness and conferring additional beauty.

GREENHOUSE.

ALSOPIHILA CAPENSIS (SOUTH AFRICA).—A very fine evergreen kind, with a stem ten or twelve feet high, and a large handsome crown of bright pale-green fronds, from three to four feet long and somewhat erect in habit. The plants of this genus require an abundant supply of water, both at the root and on the stem, to induce them to form good heads or crowns; they should also be carefully shaded when the fronds are unfolding.

CYATHEA DEALBATA (NEW ZEALAND).—This is a large-growing species, and forms a good companion for *Dicksonia antarctica*. In its native country it attains a height of twenty feet or more, but in our houses seldom exceeds eight or ten feet. The stem is almost black, slender, and branched, and bears a fine crown of broadly-oblong, twice-divided fronds of a dark-green colour above, and of a beautiful silvery white beneath, from which it has obtained in New Zealand the popular name of the "Silver Tree Fern."

CYATHEA MEDULLARIS (NEW ZEALAND).—Another gigantic species, and the largest of the family, the stem attaining a height of upwards of thirty feet, with a noble crown from twelve to twenty feet across. It is only suited for a large house.

DICKSONIA ANTARCTICA (AUSTRALIA).—This, which is one of the noblest, is also perhaps the hardest of the tree ferns.

Dicksonia antarctica.

The trunk varies considerably in thickness, and in its native country attains a height of thirty feet or more, bearing at its summit a magnificent crown of dark-green lance-shaped fronds from six to twenty feet long, beautifully arched, and becoming pendulous with age. The crown itself is frequently ten or twelve feet across, and is evergreen.

DICKSONIA SQUARROSA (NEW ZEALAND).—A very handsome species, with a black, muricated, hirsute, stiff stem, slighter than in the preceding species. The fronds are also more rigid in habit, and not so pendulous, forming a rather flat table-like crown. They vary in length from three to six feet or more, and are of a dark-green colour. The stem has often a branched appearance, from the young plants which are formed at intervals upon it. This is an excellent fern for a small house.

All the foregoing may be placed out-of-doors in summer,

but they should be put in sheltered nooks and dells, not only to protect them from high winds, but because such positions are more naturally appropriate for them than the open ground, and best represent the shady, quiet, and secluded conditions of their native habitats. When placed out thus, care should be taken to keep the stems from getting too dry, by syringing them freely whenever they seem to require it.

J. CROUCHER.

A Vegetable Conservative.—One of the most comical plants I ever had to deal with is the Turk's Cap Melocactus. My specimen came direct from Port-au-Prince by mail steamer a year and a half ago, in a basket of native soil, but neither in that nor in any other has it since exhibited the slightest radical tendency. On arrival the plant was about ten inches wide at the base, and a foot high, with the flowering cap already formed; it had a few bits of stringy root, and I cut off such portions as appeared decayed or injured; after this, despite the trial of all known means of developing root-action, it remained just as it was for nearly a year, only proving its vitality by pushing up an odd flower now and then, which flower may be roughly described as resembling an obovate coral knob, nearly an inch long and about one-third of an inch in diameter near the top. Tired of this want of progress, and wishing for some sign of development of offsets or other means of reproduction, I (thinking to give it a fresh start on a new footing) cut a slice clean off the bottom with a sharp carving-knife, and, after allowing it to dry for a few days, placed the plant on a pot of sandy soil, with a superstratum of pure sand, and put it on a dry shelf, that would have been sunny had there been any sunshine this summer; there it is still, rootless yet unchanged, a very emblem of do-nothingism. What am I to do with this vegetable conservative?—W. TEASDALE, *Headingley, Leeds.*

Oncidium Obyzatum.—Permit me to recommend this as a most valuable decorative plant, and, to those who have to provide large quantities of cut flowers, a most useful one. It is not a very old plant, having only been introduced a very few years since, consequently few have had any experience with it or know what the plant is capable of. I saw, in the select collection of E. Wright, Esq., of Granelly Hill, near Birmingham, a small plant with one lead, which produced last year two very fine spikes, and I thought Mr. Hodges, the gardener, had succeeded in growing the plant to the greatest perfection. I should then have felt very well satisfied if I could have attained like results; but last summer, I had a small plant with one lead which produced two bulbs, and these threw up three spikes and commenced flowering last March. The produce of these three spikes was some hundreds of beautiful flowers, which emitted an agreeable odour. They lasted a long time, and when they had ceased blooming, the spikes immediately commenced to throw out a great number of side shoots, and produced another crop of flowers quite equal to the first. The second crop on two spikes was finished last week, and the third spike is preparing to produce a third crop, which promises to be equal in number and effect to any of them; so that for two months or more yet it will continue to gladden myself and a few friends, who often come to see whatever curious or pretty Orchid may be in flower here.—S. EYRE, *Leck, Staffordshire.*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Jacquemontia violacea.—Let me recommend all lovers of good stove climbers to try this. For light arches, &c., in the warm stove I can find nothing to surpass it, and the sweet blue colour of the delicate cup-like flowers is much admired by all who see them.—P. L.

Grevillea Manglesi.—This is the weeping Willow of the conservatory. All the slender shoots droop like those of a weeping Willow, only even more gracefully. It is seldom seen in our gardens, but there is a good specimen which well shows the habit of the plant in one of the cool houses at Glasnevin.

Wahlenbergia hederacea and Anagallis tenella.—I have a very pleasing way of growing these interesting native plants. It is not in the bog garden, not among alpine plants, not in the hardy fernery, but in the stove. I find they grow freely on the surfaces of pots of soil requiring to be kept in a constantly moist condition, and hang down four to six inches over the edge of the pots in the most graceful manner, flowering abundantly. In many cases where sphagnum is used, a few bits of these placed in it would soon take root and grow quickly. It need scarcely be added that no plants would more agreeably help to hide the red pots that contain our specimen plants.—J. B.

Perpetual Flowering Tree Carnation La Belle.—The flowers of this beautiful variety are of the purest white, and strongly clove-scented. It was shown by Mr. Backley, of Leyton, the raiser of it, at one of the Royal Horticultural Society's meetings last month. The plant, then three years old, was trained in the form of a balloon five feet in height, and nine feet in circumference. It is one of the most free flowering of its class; indeed, so profusely does it bloom, that during all last winter, Mr. Backley cut no fewer than five dozen blossoms every week for market from this one plant. It is now in a small tub, in a compost consisting of sharp sand and decayed turf. Like others of its race, it dislikes heat; 45° in winter is as high a temperature as it can be subjected to with safety. It also flowers best without stimulants, pure water agreeing better with it than anything stronger.

THE GARDEN USES OF LIME.

LIME being a necessary and essential constituent in the food of plants, as well as a useful agent for converting inert substances existing in the soil into available material for promoting vegetation, and also for acting mechanically in lightening the texture of strong obdurate clayey soils, it is somewhat surprising that it is not more generally used for promoting these ends in gardens, more especially when it is further acknowledged that culinary vegetables, and even fruits, are finer in quality, more robust in constitution, and better coloured when grown in soils that have a proper proportion of lime in their composition, than when grown in those where it is very deficient. Yet how frequently do we see gardens, and more especially those of amateurs and cottagers, cropped, and even richly manured, continuously for long periods, without the application of such a necessary ingredient being ever thought of. But although the admixture of lime with the soil is so essentially necessary, both as a manure in itself, and as a stimulant to other manures, its application in the garden is no less beneficial for the destruction of plant-devouring slugs, injurious insects, and the unsightly growth of mosses and lichens; for all of which purposes the late winter and spring months are those in which it can be best and most beneficially applied. The ground being cropped in summer, it cannot be spread and covered in with facility unless in exceptional cases, such as between the clearing away of early and the sowing or planting of succession crops; if deferred till autumn, it becomes diminished in action from being washed and wasted during the immediately succeeding dull and rainy period of the year. Yet, even in early autumn, few would begrudge a good substantial top-dressing of quicklime to their Strawberry plants, if they were aware of the havoc which it makes among the slimy broods of the worst fruit-destroying nuisances of the past Strawberry season.

To check snails and slugs in time, commence soil-liming with the sowing of early seeds, when the days are sunny and the earth sufficiently dry to allow of working among the soil with freedom. Use hot or quick-lime liberally, and merely hoeing, raking or pointing it in on the surface; give good coatings of it also over Strawberry drills, by boxwood edgings, the sides of walls, and on other vermin-harboured places; renewing surface dustings frequently afterwards, when it becomes washed away, saturated, or inert. Nor should the extirpating effects of lime, or lime-water, upon worms pass unheeded, when they disfigure the surfaces of fine grassy lawns and bowling greens with their unsightly earthy outcasts; or when they abound among small recently-planted seedlings to such an extent as to cause their destruction by turning them out of the earth and by drawing them into their holes.

Though hot lime may not extirpate many of the numerous insects which infest fruit trees and bushes, yet it is less or more hurtful to most of them; and the best time and mode of applying it is just before the buds begin to open; then, on the morning of a quiet day that is likely to continue dry and sunny, syringe over all the branches with water, or, better still, with soap-suds, till they are thoroughly wet, then dust on the hot lime till no portion remains unwhitened. Should the weather actually continue dry through the day, and no deluging rain fall immediately after, the lime will adhere for a considerable time, and no renewal of it need be made till next year.

Mosses and lichens, even admitting that they are harmless, are nevertheless unsightly when thickly dispersed, in luxuriant growth, over fruit-tree and bush stems and branches; and we would as soon think of allowing the growth of gross weeds among fine flowers as that of these epiphytes on what are expected to be fruit-laden boughs. They are quickly destroyed by lime applied as in the last case, dry up and crumple into dust, and become dispersed, together with any insects or insect ova that may be associated with them, by the first fanning wind, or by their own gravity, light though they be, so as to leave the bark clean and smooth where before it was foul and rugged. If the application of lime to trees and bushes is made too early, it is liable to be washed off before the sun becomes sufficiently powerful to impart its full share of burning influence; while, if delayed till the young leaves and blossoms begin to protrude, these are liable to get somewhat browned or scorched: hence the propriety of choosing the time before mentioned for applying it. The caustic properties of quick-lime on the hands, and the whitening effects of it upon the clothes, are, we know, sometimes urged against its use by amateurs; but old gloves will obviate the first, and old clothes or an enveloping sheet the last of these objections—both of which are so trivial, that few will ever think of naming them after fully testing the garden uses of lime for accomplishing all, or any, of the purposes for which it is herein recommended.

Kew-rious Coincidence.—It is said that Mr. Ayrton was born at Kew in 1816.

THE PASHIUBA PALM.

AMONG the singular aspects of vegetation which meet the eye of the traveller in tropical regions, none is more striking and remarkable than that presented by the Pashiúba (or Paxiúba) Palm of Brazil (*Iriartea exorrhiza*). The first sight of this tree suggests the idea that some careful hand has been at the trouble of placing round its base a tree-guard to protect the stem, somewhat after the manner in which the trees in our parks are railed and fenced in from cattle. A nearer approach, however, discloses the fact that the supposed tree-guard is neither more nor less than the roots of the tree itself, which are disposed in this strange fashion. These roots are of the kind known as "aërial," and spring from the trunk above the ground, new ones being successively produced from a higher point than the last. They take an oblique or diagonal direction until they reach the ground, into which they descend and root themselves. As fresh ones appear, those underneath decay and die off, leaving the tree supported by a hollow cone of roots, which is sometimes so high that a man may stand in the centre, with the stem of the tree sixty or seventy feet in length, immediately over his head. These roots are densely covered with small, hard, tubercular prickles, and are used by the natives as graters for reducing the inside of the cocoa-nut to a pulpy mass to be boiled with rice and water. Two of these graters were sent some time since by Mr. Wallace to the Museum at Kew. The same peculiar mode of growth is exhibited by *Iriartea ventricosa* and several allied species.

MEMORANDUM OF THE FIRST COMMISSIONER ON THE MANAGEMENT OF KEW GARDENS.

The powers and duties of management in relation to Kew Gardens, in common with other parks and gardens, are by statute vested in the Commissioners of her Majesty's Works and Public Buildings. Anything authorised to be done by the Commissioners may be done by the First Commissioner, subject to the orders of the Treasury. The Commissioners are empowered to appoint, with the approval of the Treasury, the technical officers under the Board, and the Treasury is empowered to appoint the secretary, clerks, messengers, and officers, except the technical officers. The Commissioners are empowered to remove any of the officers of the department. There does not appear to have been at any time any organised code of instructions for the management of Kew Gardens, but it seems that the business has been conducted as follows:—

DEPARTMENTS.

The establishment at Kew, for the purposes of administration, subject to the authority of the Commissioners, has been divided into four branches—Botany, Horticulture, Police, and Works. The department of botany is under the immediate direction and control of the Director of Kew Gardens, assisted by a special staff of officers. It comprises the Botanic Museum and Library, the collection and interchange of botanical specimens, whether for the herbarium or cultivation, and all other matters pertaining to the pursuit of botanical science. The department of horticulture is under the immediate cultivation of the Curator of Kew Gardens, subject to the orders and control of the Director of Kew Gardens, as the responsible head. The Curator carries on the cultivation of the gardens with a large staff of gardeners and workmen. The police comprises park constables and gatekeepers, appointed by the Commissioners, and police constables under the Metropolitan Police Commissioners, assisted by the gardeners at Kew, acting as constables as required. All questions relating to the use of the gardens by the public are determined by the Commissioners on the reports of the Director. The works are carried on under the direction of an assistant surveyor of works, an officer of the Commissioners, who reports to them directly, not through the Director of Kew Gardens. Dr. Hooker having for some years held the office of assistant director, was appointed Director in 1865, by a letter from the First Commissioner, enjoining him to give his whole time to the business of his office, and to observe strictly such orders as he might receive from the First Commissioner. The office of assistant director was then abolished as unnecessary. The present curator of Kew Gardens, Mr. Smith, was appointed on the superannuation of his predecessor in the year 1864.

BOTANY.

With the department of botany, it would seem that the Commissioners have not interfered beyond deciding questions affecting expenditure, of which the following are examples:—On the application of the Director in 1864, the Commissioners communicated to him that the Treasury had sanctioned the publication of the "Flora of

THE FASHUBA PAINT.

Tropical Africa," through the medium of the Stationery Office, in whose estimates the cost was to be charged. In 1868 the first volume was published, and in 1871 the second. It becoming necessary to apply to the Treasury respecting a payment on account of it, their lordships directed that the stock, after deducting the presentation copies, should be transferred to the Stationery Office. This was communicated to Dr. Hooker on the 29th of September 1871. A letter was then received by the Commissioners from the Stationery Office, asking for certain particulars relating to the work, with a view to the sale of the surplus stock. This was referred to Dr. Hooker for report, when he replied on the 22nd of February following that, in his opinion, the copies ought not to be sold. A further correspondence took place, and ultimately Dr. Hooker was informed, in accordance with the views of the Treasury, that it would be inconsistent with their views that a work of the kind should not be kept for sale as well as for occasional presentation, and that the principal stock should be kept at the Stationery Office.

HORTICULTURE.

In 1869 Dr. Hooker applied to be sent as a botanical commissioner to St. Petersburg, at the public cost, but the Commissioners, in accordance with instructions from the Treasury, declined to comply with his application. In the department of horticulture, the degree of interference and control by the Commissioners has varied with successive First Commissioners. In Dr. Hooker's report on Kew Gardens for 1870, he states that the plantations made by Sir William Hooker failed, because "permission could not be obtained either to make sufficient clearances, or to disturb the roots of the old trees by trenching the ground;" and on being requested by the First Commissioner to elucidate this statement, Dr. Hooker has given the following graphic account of the control of former First Commissioners:—"My statement respecting permission to thin, &c., the trees in the pleasure-grounds had reference to the time (previous to 1865) when all matters of importance were discussed between the First Commissioner and the Director, before becoming the subject of official correspondence with the Board. I was myself present at several conferences on this subject between my father, Mr. Philipps, and Mr. Milne, previous to 1848, when the refusal in question was given, on the ground that . . . had prohibited the removal of any old trees whatever. Since my return from India in 1851, my predecessor, in my presence, drew the attention of more than one First Commissioner to the state of the trees, with a view to making clearances, but in vain. On one such occasion, he and I had a large number of old trees marked, with a view to the First Commissioner approving of their removal; but on his inspecting them, he ordered them to be headed instead. Subsequently some of these very marked trees, then stark dead, were pointed out to another First Commissioner as examples of the state so many were coming to, and permission asked to write to the Board and suggest the removal of many trees, with a view to replanting; but the First Commissioner, in my presence, shook his head." Again, Dr. Hooker has stated, that when Lord Llanover introduced the present system of flower beds, he opposed it almost rebelliously, but it is now one of the chief attractions to the hundreds of thousands who visit the gardens. It is well known that Lord Llanover greatly increased the efficiency of the Commissioner's administration, and the records of the office, of which a few extracts are annexed, will show how vigorously he exercised the controlling power of the Commissioners over Kew Gardens.

KEW AS A PUBLIC NURSERY.

But the management of Kew Gardens was not limited to their own requirements. They were made use of as a nursery for the other parks and gardens under the control of the Commissioners. The result of this does not seem to have been satisfactory, as shown by a letter of the Director proposing to sell 10,000 elms, because the superintendents of other gardens had no use for them, whilst at the same time they were unable to find in Kew Gardens the trees they required. The First Commissioner has, however, taken no part in the horticulture of Kew Gardens, nor has he interfered with it, except on the occasion when the Director of the gardens represented that it was necessary to expend the sum of £1,500 in horticulture, to restore the sylvan scenery of the park, of which he submitted a specification. As soon as the sanction of the Treasury was obtained, Dr. Hooker received the requisite instructions from the First Commissioner, leaving the mode in which they should be carried out to the Director; thus the only act of the First Commissioner respecting the horticulture of the gardens has been to grant that which his predecessors had denied. The estimates for the expenditure on botany, and horticulture, and police, are prepared annually by the Director of the gardens, and submitted to the Commissioners for their consideration, in accordance with instructions forwarded to him annually in varying terms; but it is to be observed that these

are not the whole estimates for the gardens, but only for the services in the gardens under the Director's charge. When the First Commissioners have been of opinion that the amount asked for was excessive, it has been customary for them in communication, and in some cases without communication, with the Director, to strike out parts of the estimates. But until the money has been voted by Parliament, the changes which have been made have rarely been notified to the Director, and in most cases he has not been informed how much was submitted to Parliament until the estimates have been printed, and a copy has been sent to him. Exceptions to the usual course have arisen in cases of important services which have been the subject of correspondence or discussion.

DR. HOOKER AND THE FIRST COMMISSIONER.

In discharging the duties of the Director under the Commissioners it was the practice of the late Director to attend the First Commissioner frequently at the office of works, and also to attend the assistant secretary, who was intrusted with the business of the parks. Dr. Hooker appears not to have continued this practice to the same extent, although he has on frequent occasions called at the office to discuss changes under consideration. It has also become the practice to send the Curator of the gardens to the office to explain matters of account, and to consult the secretary upon some pressing business. The First Commissioner, shortly after his appointment, informed Dr. Hooker that he should be at all times happy to see him. To show his confidence in Dr. Hooker, he requested him to examine into and report on the attacks which had been made in a work recently published on the administration of the parks and gardens under the charge of the Commissioners, which report Dr. Hooker obligingly furnished. The First Commissioner not having interfered either with botany or horticulture, the Director has transacted the business through the secretary, though it was quite open to him to transact it with the First Commissioner. Dr. Hooker has only thought fit to call on the First Commissioner on two or three occasions, when specially desired.

WORKS.

The Department of Works involves different considerations. Lord Llanover particularly reformed the administration of the parks and gardens. With them the First Commissioner has interfered as little as possible, but he has undertaken to effect an entire reform of the administration of the Department of Works. Before 1869 the administration of works under the Commissioners was committed to the care of the assistant surveyors of the department, or of other persons specially employed on particular works or duties. The architect and surveyor of the Commissioners not being required to give his whole time to the public business, there was no superintending officer to aid the Commissioners in the regular supervision and control of the various persons employed under them in relation to works. In Kew Gardens the works were entrusted to the assistant surveyor of the district in which they are situate, and were carried on by him in the same manner as all other works in his districts. It was his duty to ascertain by personal inspection of the works, and by communication with the persons to whom the use of buildings was entrusted, what works or repairs would be required in each financial year; and to form his own judgment on all requisitions or suggestions made to him by such persons. Mr. Storie has for many years held the office of assistant surveyor of the district. He has conducted his business at Kew Gardens through a resident clerk of the works and a mechanical artificer. When works of importance were to be undertaken in the district, they were sometimes entrusted to the assistant surveyor, and sometimes to architects or other persons specially employed for the occasion. The general relations of the assistant surveyor to the Director of Kew Gardens are illustrated by a letter of Sir William Hooker showing how the duties were performed, and that in all the details, including the work of heating, there was no real difficulty in carrying on those services. With regard to larger works at Kew, the Commissioners employed Mr. Decimus Burton to construct the conservatory, or temperate house, the Director being required to furnish a statement of the horticultural requirements. In 1863 part of the work was altered by the direction of the Commissioners, under the orders of the Treasury, without consulting the Director. When informed of the change, he vigorously protested against it. The Commissioners, with the sanction of the Treasury, proceeded with the work in 1864. In 1855 the Commissioners determined to erect a museum. The steps taken for that purpose, as regards the Director at Kew, are illustrated by his letter to the First Commissioner, and by the letter of the Secretary intimating to the Director that the First Commissioner had given instructions to Mr. Storie, the Assistant Surveyor, for the works of the museum at Kew Gardens to be proceeded with forthwith on the site which he had selected near the water, and to request that the Director would state how much space would be required for

the herbarium and how much for the library. The organisation of the water supply for Kew Gardens was placed in the hands of Mr. Simpson, the engineer, who prepared plans and estimates for that service, and carried it out under his own superintendence. The Assistant Surveyor has prepared his own estimates for the services in his charge at Kew Gardens, and submitted them to the consideration of the First Commissioner, who has made such inquiries and modifications as he deemed proper. The estimates of the Director and Assistant Surveyor have then been framed into one estimate, and added to the other estimates of the Commissioners under the general head of Royal Parks and Gardens, and submitted to the Treasury for sanction to be laid before Parliament. In passing this estimate it has been the duty of the First Commissioner to have regard not merely to the amount for each park or garden, but to the whole expenditure proposed for the year.

THE HEATING APPARATUS.

In October 1865 the new Curator of the gardens called attention to certain defects in the heating of the houses there, in a letter to the Director, which he forwarded to the Commissioners. Subsequently Dr. Hooker forwarded a proposal of Mr. Ormson, who carries on the business of horticultural works at Chelsea, to put up one of his patent boilers. This proposal was approved conditionally, but the First Commissioner determined on July 1, 1866, to appoint Dr. Hooker, in conjunction with Mr. Starie, the Assistant Surveyor, Mr. Smith, the Curator, and Mr. Ormson or Mr. Weeks, another person in the same business, to report to the Board the result arrived at as to the best means of remedying the defects complained of, and of economising fuel. On May 29, 1867, Dr. Hooker, Mr. Smith, and Mr. Starie, made a report. They agreed in some recommendations, but differed in others. Mr. Starie did not recommend Mr. Ormson's patent boiler, whilst Dr. Hooker and Mr. Smith recommended he should be permitted to fix one of them. Mr. Ormson made a separate report. These were transmitted by Dr. Hooker to the Commissioners. The First Commissioner having considered these reports and other suggestions, at length, on June 19th, after communicating with Dr. Hooker, determined to appoint an independent committee, composed of Mr. Eyles, of the Royal Horticultural Society's Gardens, Mr. W. Ingram, the Duke of Rutland's gardener, with Dr. Percy, the superintendent of heating and ventilating the Palace of Westminster, to inquire into the system of heating the houses at Kew Gardens, with the view of considering and suggesting what improvements could be made. Of this the Director was informed on the 26th of June following, after the Treasury sanction had been obtained. The business was thus taken altogether out of the hands of the Director and Assistant Surveyor. A report was made in August 1867 to the First Commissioner by Messrs. Eyles and Ingram, in which Dr. Percy did not join. They recommended various improvements and works, and concluded as follows:—"We would also recommend that a useful man, capable of making any alteration or repairs in the heating department at Kew, also to keep the department in good working condition, be added to the staff, and to be placed under the direction of the Curator; he being wholly responsible for the good cultivation of the valuable collections of plants in the Royal Botanic Gardens at Kew, should, in our opinion, exercise control over the heating department, supplying, as it does, one of the vital elements of his success." A report having been received by the First Commissioner from the Director respecting the works, it was referred to the Assistant Surveyor, and his reports were also received, to which the Director replied in a further report. Dr. Hooker was then authorised by the Commissioners to carry out certain urgent services for heating. On October 29, 1867, the Director was informed, by letter, that the First Commissioner, having had under his consideration various reports on the heating of the plant houses, &c., at the Royal Gardens, Kew, and the questions to which they have given rise, wished that for the future all responsibility connected with warming and ventilating the palm and plant houses and museums, and with the preparation of the estimates necessary for such purposes, should devolve upon him as the Director of the Royal Gardens, the works being conducted under the superintendence of the Board's surveyor for the country district, and that the estimates for the ordinary works of repair and maintenance should rest with that officer, who will, in preparing them, place himself in communication with the Director. Under this arrangement various services were carried on at a considerable outlay; but the First Commissioner has been unable to discover that any person professionally conversant with the technical business of construction held himself responsible for the technical construction of the work. The contractor would seem, in these respects, to have been his own master. At the same time, considering the defective organisation of the department, the proceedings above noticed might be regarded as a natural result, for which no one was to blame.

(To be continued.)

THE ARBORETUM.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE CYPRIAN GUM CISTUS (CISTUS CYPRIUS).

THIS forms a hardy sub-evergreen shrub from four to five feet high, and produces flowers profusely in succession during the months of June and July. It is, perhaps, the very handsomest of the genus, having white flowers of great size and beauty. It is a native of the Island of Cyprus, where it grows on hills; it will, however, succeed in any good garden soil that is rather dry, and is easily increased either by means of seeds or cuttings. It was first introduced in 1800. The leaves are opposite, oblong-lanceolate, entire, flat, stalked and sub-evergreen, with the upper surface smooth and the under one clothed with hoary down. The branches are long, slender, and rather spreading, and the young shoots smooth and more or less covered with a clammy gluten. The flowers are produced in great abundance on terminal, many-flowered, deciduous-bracted peduncles, and are from 2½ to 3 inches across; they are five-petalled, pure white, with a dark rich brownish crimson stellate blotch near the base of each petal, and orange-coloured at the base.

Cistus Cyprinus.

The blossoms, in fact, resemble a large single rose, but are of short duration, only lasting, in general, a single day. The fruit is a dry five-celled capsule, more or less covered by the calyx, and ripens in September. The Cyprian Gum Cistus forms a splendid plant for ornamenting rockwork or dry banks, but it requires to be fully exposed to the sun, as the flowers only expand under the influence of bright light. This species is generally known in the nurseries under the false name of Cistus ladaniferus, which is a different kind, having white flowers wanting the rich dark blotch on the petals, and not much more than half the size of those of this plant. The synonyms are Cistus ladaniferus planifolius, C. ladaniferus maculatus, and C. salicifolius.

THE ORIENTAL BLADDER SENNA (COLUTEA CRUENTA).

THIS forms a showy, free-growing, many-stemmed, round-headed, deciduous bush, from four to eight feet in height, which thrives well in any common garden soil, and produces a fine effect either planted singly on the lawn or in the shrubbery. It is a native of Iberia and the Levant, and is readily increased by seeds, which are produced in great abundance. It was first introduced in 1731. The leaves are alternate, pinnate, glaucous, and deciduous, with from four to six pairs of leaflets and an odd one; the leaflets are rather small, obovate, emarginate or slightly lobed at the apex, rounded at the base, and mostly opposite, but sometimes otherwise; they are bright green and smooth on the upper surface, downy beneath, and set rather distantly on the stalk. The young shoots and petioles are pubescent. The flowers are pea-shaped, rather large, and of a reddish-copper colour, with a yellow spot at the base of the standard or upper petal; they are produced in June or July in from three to six-flowered axillary racemes, which are a little shorter than the leaves. The fruit is a dry membranaceous, inflated, oval, boat-formed, reddish pod, which when ripe, in August, opens at the point. The synonyms are Colutea orientalis and sanguinea.

New Way of Cutting Wood.—A curious invention has just been patented through the American Patent Agency by Dr. Robinson. A galvanic current in sufficient quantity, when passed over fine platinum wire, raises its temperature to a white heat. The most important application of the principle consists in the employment of the heated wire in

surgical operations as a substitute for the knife. It was found that red-hot wire cuts or burns its way through the flesh. The inventor discovered that wood, a comparatively dry substance even when green, could be cut in the same way. By arranging the wire with handles or other means, so as to guide it readily, trees, logs, or plants may be cut as desired. There is here, therefore, a simple and easily applied force, which may be employed to fell trees, divide them into logs, and perform all the operations of the saw and the axe. The surface of the wood is slightly charred, but the black layer is very thin. The battery employed need only be of the simplest character.

Trees and Bedding Out.—A correspondent sends us a complaint against the trees which interfere with his "bedding out." Long lines might be longer only for these disagreeable impediments, which also cast a shade injurious to Tom Thumb and his brethren. We are really sorry for him, but cannot allow him more space than is necessary to barely explain the amiable nature of his desires, which seem to be that, as myriads of precious plants were thrown on the rubbish heap to make way for the ribbon system, it would be much in favour of that system if most of the trees that cumber our pleasure grounds were sent to the timber yard. We quite agree with him in one point—that it would be easier to make what he calls a "splendid display." If, however, we may venture to offer a word of advice, it is that it would, on the whole, be better to seek for some flat already naked surface on which to operate.

Epping Forest.—This forest, which little more than thirty years ago consisted of between 6,000 and 7,000 acres, now contains only about 3,000 acres. In that short period, by legitimate enclosure and by illegal encroachment, the beautiful wood has been reduced by more than a half in its extent. It is impossible to say, until the Commission appointed under the Epping Forest Bills has completed its inquiry and made its report, how many of the enclosures are legal and how many illegal; or, in fact, what extent of the forest is actually possessed at the present time by the people. It is almost inexplicable that so much of so beautiful a forest should have already disappeared. Much more would doubtless have gone in the short period of twelve months that has elapsed, since the movement for its preservation acquired an additional impetus by the action of the Forest Fund Committee, but for the vigorous action of that Committee. It was found to be an easy matter for lords of manors and others to add by illegal enclosure to the land already possessed by them. It was only necessary to throw their fences further out into the forest; and this process, if quietly and gradually accomplished, would frequently pass unnoticed. When a bold and unscrupulous enclosure was made, probably the frequenters of the forest would look and wonder at the change; but no steps would be taken to bring the offenders who thus despoiled the people of their open space before the courts of law. For thirty years this kind of thing has been going on; and by some means or another, legal or illegal—but we fear, mostly by illegal means—Epping Forest has been half eaten away.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Dacrydium Franklini.—Dr. Moore informs us that Mr. McNab, of the Edinburgh Botanic Garden, finds this interesting New Zealand Conifer to be perfectly hardy in the Botanic Garden there. As it is one of the most graceful objects that exists in the shape of a tree, we are sure many will be glad to hear this. We hope to see it tried extensively in the milder districts.

Replanting Evergreen Oaks.—Some of the old evergreen Oaks in the College Botanic Garden at Dublin having become too large for their neighbours, and their destruction or removal being inevitable, Mr. Bain headed them close in, to within seven feet or so of the ground, and treated the roots much as if the stumps were to be thrown away. Planted again, these stumps have in all cases pushed vigorously, and some of them now form fine specimens.

Berberis fascicularis.—This forms one of the most beautiful standard shrubs we have, and is also a grand plant for covering walls from seven to ten feet high. The habit is neat and well furnished, and the aspect of foliage distinct and pleasing. Specimens on my lawn in Hampshire are eight feet through, and about seven feet high. *B. tenuifolia* is also forming a most ornamental shrub. —A. D. S.—[This last is also very fine at Glasnevin.]

Ornamental Hypericums.—Will you kindly tell me the name of the handsome *Hypericum* sent, and tell me if there are any other kinds worthy of a place beside it? I find it an invaluable shrub; the waxy buds are like those of miniature yellow Roses.—H. ELLIS. [It is the fine *H. oblongifolium*; *H. nepalense* is nearly as good, but more fragile, somewhat like *H. virgatum* in its habit. Both are as valuable as the common St. John's Wort, *H. calycinum*.]

Dracena augustifolia as a hardy evergreen.—This stately plant, an ornament of well-furnished conservatories, is now growing freely in the open air in the People's Garden at Dublin. Specimens planted at Woodstock, by Mr. McDonald, some years ago, are now five inches in diameter of stem. At Bicton, when we were last there, the plant was hardy and well-established. It is likely therefore that in many districts this noble plant will prove as useful as *Yucca recurva*.

Spiraea arifolia as a Wall Plant.—Many of us admire this lovely species as a shrub or low tree, but its value as a wall plant is not so well known. About half way up the long straight avenue which leads from Blackrock to Mount Merrion, near Dublin, there is a house (Villa Nova, Mr. Gilbert's), one side of which is covered with *Spiraea arifolia* to the height of about twenty-four feet; the plant seemed to have been in flower for months, and was yet, on August 8th, still producing its large panicles of unfolded buds like small pearls. A more strikingly beautiful object in the way of a wall plant it would be difficult to imagine.

Invigorating old Hollies.—Many of the fine Hollies now in the College gardens at Dublin, were a few years ago in a half-exhausted state, and were successfully treated by Mr. Bain in a novel way. A strip of bark two inches wide and about three inches long was removed from the wood, and a mound of good earth raised about the tree so as to cover this. New roots were soon emitted, and the trees soon assumed a healthy character. In other cases old plants were taken up and sunk a foot or so in the ground, a strip of bark being also taken off in this case. These sent out new and vigorous roots from the newly buried stem, while the original roots perished.

MARKET GARDENS ROUND LONDON.

BY OUR SPECIAL REPORTER.

MR. GEORGE STEEL'S, PARSON'S GREEN, FULHAM.

(Concluded from p. 132.)

VEGETABLE MARROW.

THIS is one of the principal vegetables at present in marketable condition. Mr. Steel grows several acres of Marrows. Those first planted have been in good bearing for over ten weeks, and the youngest have just been planted out on ground cleared of the latest Cauliflower crop, in lines twelve feet apart and nearly half that distance plant from plant. The earliest planted were put out the first week in April. For them trenches were dug out about twenty inches deep and from two to three feet in width, and filled with fermenting manure, which was covered over with the soil that had been thrown out of the trenches. The plants were then planted and covered with sashes or handlights, around and over which, for some time after, litter was placed at night. This plantation is now in a most flourishing condition, and the sashes and handlights having been long since removed; the surface of the soil was strewn with litter, and now the vines have met and run in amongst one another quite thickly. The plants are in excellent fruit-producing condition. The second plantation was made by digging out square holes sufficiently large to contain a good barrowful of fermenting manure, which was immediately placed therein and the whole covered over with the soil and treated as the others. The third plantation was treated precisely similar to the second, only that a short interval elapsed between the times of planting. The fourth plantation is a very large one, and is made on the bare ground, without any artificial assistance whatever, further than protection by means of handlights; some of them being less fortunate than others, had only round vegetable-baskets placed over them, but the cold and damp were too much for some of them, consequently they succumbed, and after a short time were replaced by others from the reserved stock. The sudden change the weather took in June did them a favourable turn, and ever since then they have grown amazingly, and although not much more than two months in the ground, they, as well as all other former plantations are in full bearing. They are planted in rows fifteen feet apart, and now occupy nearly all the space. Other plantations have since then been made, the last one in the second week of last month. This is planted out like the others, only the plants never had any kind of protection whatever. This is a crop that does not do well in dry grounds, and in such places gardeners do not grow it, for it would not pay the extra trouble bestowed on it in the way of carting water, &c. The plantations are gone over three times a week, and all fruit fit for market is cut for that purpose, the largest cutting being left till Friday, as there is always a greater sale for them on Saturdays than earlier in the week. The great spaces left between them in their earlier growth are not left empty, but on the contrary they are cropped with Radishes, Lettuces, Cauliflowers, Turnips, &c.

RHUBARB.

This forms an important spring crop, and Mr. Steel has plantations of it several acres in extent, besides a great quantity grown under orchard trees. In February the crowns are individually covered with a little heap of rank litter, from under which the leaves come up clean and crisp. As often as a good gathering can be had it is secured for market; or sometimes one plantation is cut for this market day, and another separate one for the next, and so on, thus having a sale of leaves every market day. For a long time after the litter could be dispensed with as a protection from frost, it is retained solely for the purpose of obtaining nicely coloured, crisp, and tender stalks, for they find a much readier market than those that are unprotected, however young. In preparing them for market they are tied into bundles with willow twigs. The distance between the rows of rhubarb, and also the plants in the rows, both in the open ground and under trees, is about three feet. Those under the trees are not mulched over the crowns in spring as are those in the open ground, because being partially shaded and protected by the branches, and the

crowns not being naturally quite so strong, their produce unprotected is thus more tender than that of the other plantations. They are not, however, so much shaded as to cause them to come up spindly, for they are several weeks in good bearing before the trees begin to break forth into leaf, consequently the naked branches act more as a protection than as a shade.

SEAKALE.

Of this, Mr. Steel has some acres of excellent plants in lines about eighteen inches apart each way. These were planted between Cauliflowers the first week in April, small pieces of roots being used that were cut off those that were taken up for forcing. These roots are cut up into pieces about four inches long, laid quite thickly on a prepared bed, and then covered with a few inches of soil. At planting time they are lifted, placed in baskets, and planted with a dibber perpendicularly in lines at the above distance between Cabbages, Cauliflowers, or other crops. Here they are allowed to remain, and the other crop being removed, one of Lettuce is put in, which occupies the space until the Seakale comes up and unfolds its leaves. The Lettuces do not take long before they are ready for market, and are removed in good time to permit of the ground being given over entirely to the Seakale. These plants can either be lifted wholly for forcing, or every second line can be lifted for that purpose, and the other left for blanching in the open ground. Forcing is performed in the usual manner, by lifting the roots and placing them in frames, covering them with some soil, and the frames with some litter to darken them. In the open ground blanching is done by earthing up the rows from the intervening spaces just as is done with Asparagus. The shoots, as they appear above ground, are cut away at their base, leaving the neck uncovered. From this cut several shoots may spring, but they are removed, leaving only three, or more frequently two, to remain throughout the summer.

SPINACH.

This is only grown in spring, when there is a good demand for it. Spaces under trees are often sown broadcast with it, and, as the trees are not furnished with leaves, they do not cause so much shade as would endanger the plants becoming drawn, thus preventing them from forming those fine healthy thick leaves so much sought after. Ground is also prepared, and the seed sown thinly broadcast over the whole; then Cauliflowers are planted at the usual distance apart. By the time the Spinach has come up the Cauliflowers will have become well established, so that the Spinach, which as soon as ready is removed for market, could not injure it much. When the Spinach is removed, the Cauliflowers will require all the space, consequently the ground is gone over at once, hoed, allowed to rest a few days, then some soil is drawn to the base of the plants. For market the Spinach is packed firmly in round vegetable baskets, and also in hampers of any size convenient for handling.

TOMATOES.

These are planted out earlier in Mr. Steel's grounds than they are in any other garden round London. This is owing to the sheltered position they occupy. Mr. Steel is a large grower of Mushrooms, and, as the ridges bear scarcely anything during the summer, they are partially deprived of their covering of litter, and along the base of these ridges on each side the Tomatoes are planted. The ridges being about four feet through have a space of two feet between each; the plants are planted three feet apart along the base of these ridges, and as they advance in growth they are pegged to the ridges. Here they are sheltered, and the whole surface of the ridges are mulched with litter, with a mulching in the bottom trench, which of itself, being a little below the ordinary surface, retains the moisture well, and in dry seasons in this respect is very beneficial. On the south side the fruit are fast swelling, some of them being already nine inches in circumference; those at the back are a little more backward, but still in advance of those planted in more open positions. The second earliest are planted in a south border, and attached to wooden stakes, and are forming fruit. The third or main planting occupies the ground that was used for the earliest Cauliflowers; they are also in bloom and have fruit beginning to form, the plants being tied to upright stakes. This proves the truth of the Oriental saying, that their lands produce three crops

a year. In very early spring the Cauliflower is planted; in February or March the ground amongst them is planted with Lettuces, which, as the Cauliflowers are removed, have the room to themselves, and they soon are also displaced for market; then comes the turn for the Tomatoes. During very dry weather they are heavily watered, but this has been done only once this season, and that just before the rains of the last few weeks.

TURNIPS.

Turnips also play a prominent part as a spring crop, but later in the year they are totally discarded, to make room for more suitable and money-making crops. They do not occupy the ground long, and consequently are very convenient as early vegetables. They are sometimes grown in broad beds, protected with some litter, just as they do with Radishes, and in this way good eatable Turnips are got by the latter half of April, soon after private gardeners have begun to think about sowing a few. Later in the season, however, a piece of ground becoming empty by clearing off Radishes, Cabbages, Celery, or other crops, is dug, harrowed, sown broadcast, and then rolled. This being done in April finishes Mr. Steel's Turnip crop. Celery ground is most commonly retained for Cauliflowers.

MOSS ROSES.

These are found to do pretty well under fruit trees, when the shade is not too dense. They are planted in lines three feet apart, and throughout the summer produce a great profusion of blooms. The space between them is filled up with Coleworts.

STOCKS.

These are the only annual or herbaceous flowering plants that are grown for sale in this market garden. They are planted amongst Moss Roses, where they can either be kept for affording cut blooms for immediate use, or for yielding seed to produce seedling plants for sale in spring.

FRUIT TREES AND BUSHES.

Of these there are several acres in Mr. Steel's grounds, and on some of his Pear trees there is a good crop, though, taking them on an average, the quantity of fruit may be rather below that of ordinary years; he has, however, no reason to complain, for many will not get as much fruit from their orchards this season as will pay their rent. Secondary sized trees are planted in lines about ten feet apart, and their distance in the row is regulated by their size. Beneath these Gooseberry bushes are grown, a row being put in a line with the trees and one down the space in the centre. The space between the Gooseberry bushes is cropped with Coleworts or Rhubarb. In some parts, beneath large trees, Rhubarb only is planted in rows three feet apart each way. The prolificness of this crop under such circumstances is wonderful; the leaves come up earlier in the spring than in the open ground, and at that time the trees being bare of foliage they have a fair amount of light. Where the trees are not too closely set, Moss Roses are grown in three-foot lines between them, for affording cut flowers. The alleys between the Roses again are cropped with Coleworts. When digging the ground in the orchard in winter, all good suckers are preserved, and in March, the roots and points of the shoots being shortened, they are planted in lines two feet apart, in deeply-worked ground, where they will remain until they are grafted the next spring, or some of them may be kept to the succeeding year. Gooseberry and Currant bushes are not propagated here from single cuttings, as is the case in nurseries and private gardens, but from layers. In March, whole rows of these bushes are layered quite flat on the ground and slightly covered with soil. When they begin to grow they push shoots from all the eyes. No sooner have these young shoots attained a length of six inches or so, than they receive another good earthing up, which is done by loosening the soil in the alleys between them, and working it in amongst the layered branches so as to cover the base of each of the shoots to a depth of a few inches. If necessary, and time can be spared, another earthing up is given. They are thus allowed to remain throughout the summer, receiving no further attention than that of keeping them free from weeds. In October they are lifted, cut up into pieces having three shoots each, and transplanted in nursery lines, in which they are allowed to remain

for another year; they are then lifted and transplanted to where they are to remain permanently, and all surplus stock is sold. The advantage of having three branches springing directly from the root instead of one is this, viz., that market gardeners commonly grow small fruit bushes under trees, where they are liable to many disasters, and if they happen to lose a limb, still two strong ones are left; while had there been only one shoot springing directly from the root, a new plant would be necessary.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 150.)

SOWING AND TREATMENT OF SEEDS UNTIL THEY GERMINATE.

POSITION.

THE raising of plants from seeds in a room can only be attempted on a small scale, as, though the pots containing the seeds may be kept in a position at a distance from the window as long as the seeds have not germinated, yet as soon as the young plants appear they must be placed close to the window. Moreover, it is only those seeds which are slow in germinating which can be kept for any length of time in a position at a distance from the window, while those of speedier growth must be placed close to the window very soon after they are sown. Besides, seeds of plants from warm climates should have a warm position in a heated room, and those of plants from cold and temperate climes require a corresponding temperature in a room which is not heated. Fast-growing annuals and perennials, which are intended for summer-flowering, may be sown as soon as the season permits, on flower-stands or other places in the open air. Care should be taken to prevent the drip from the roof, or from trees planted near the house, from falling on the pots in which the seeds are sown. Whoever wishes to try the experiment of raising tropical plants from seeds, which will require a heat of at least from 75° to 90° Fahr., must provide boxes in the shape of hotbeds, which will be useful either for seeds or for cuttings. These boxes should be as long as the breadth of the room-window, and about two feet wide. The back of the box should be about two feet high, and the front two or three inches lower. On the top is placed a light, similar to that of a hotbed, but made as light as possible, and fitting well into its place. At the distance of fourteen inches from the top a horizontal bottom pierced with holes is let in, which divides the boxes into an upper and a lower compartment. The upper compartment is for the reception of the pots. The holes in the bottom are covered with broken potsherds, and sawdust is filled in till it reaches within an inch of the top of the box. In this sawdust, which ferments gently, and should be stirred up from time to time or replaced with fresh, the pans containing the seeds are plunged up to the rims. The lower compartment is quite closed up, but has a door in the back. In order to heat the box, closed vessels containing boiling water are introduced through this door into the lower part, as many being placed there as it will hold. These may be either tin or earthenware vessels furnished with covers, or for want of better, the earthenware bottles used for holding mineral waters may be employed. It will be sufficient to fill these vessels once every twenty-four hours with hot water. Instead of these closed vessels, a tin or copper reservoir may be placed in the lower compartment. This is to be half filled with water, and heated by a spirit lamp placed underneath. This, however, is a much more costly apparatus than the other, and possesses no advantages over it in point of heating. Such a box as we have described, may, to suit its position in the window of the apartment, be tastefully constructed of wood, sheet-iron, or copper. A thermometer should be placed inside to regulate the temperature, which should range from 70° to 90° Fahr.

SOWING.

In sowing, ordinary pots, or still better flat pans, are generally used. In the latter the soil is better exposed to the air, and is less liable to become sour from the moisture which it must receive in order to promote the germination of the seeds. The bottom of the pot or pan should be covered with

a good layer of broken potsherds in order to secure perfect drainage. The pot or pan is then filled with suitable soil up to within from one-sixth to one-third of an inch from the top of the sides, so that the water may not run over in watering. The soil is then made even, and well pressed down with a smooth, flat, round piece of wood, having a handle let into the middle, and it is then ready for receiving the seed. The seed is then sprinkled over it in such quantity that when the young plants come up they will not stand too thickly together, as a crowded state during their first growth is not calculated to produce strong specimens afterwards. It is easy to guard against this in the case of large seeds, but very small seeds, such as those of Calceolarias, Gesneraceæ, Ericas, &c., should be mixed with fine white sand, placed on a piece of paper, and carefully scattered over the surface. The white sand will indicate the equable distribution of the seeds. Very small seeds are either not covered at all, or only to the depth of one-fourth of a line with fine sand, or with a thin layer of finely-chopped moss. The latter is to be preferred with the seeds of Ericas, Azaleas, Rhododendrons, Epacrises, and like plants. Larger seeds should, after sowing, be pressed down with the hand, or with a flat board, into the soil, and then covered with some of the same kind of soil as that with which the pot is filled, to about the same depth as the diameter of the seeds.

TREATMENT UNTIL THE SEEDS GERMINATE.

After the seed is sown, the pot should be watered with lukewarm water from a watering-can with a fine rose. This should be done carefully so as not to disturb the surface of the soil, and the finer and smaller the seed the greater necessity is there for watering cautiously. Pots in which very small seeds are sown without being covered, or only slightly so, are best watered by placing them in a saucer full of water, and using one of the refreshers previously described to water the surface of the soil. Until the seeds germinate, the surface of the soil should be kept moderately moist. An excess of moisture should be guarded against, so that no water may be allowed to stand in the saucer. This in the case of slowly-germinating seeds would produce sourness in the soil, which would prove very injurious to the young plants. The larger seeds should be watered frequently but sparingly. In the case of small seeds, water should not be placed in the saucer more frequently than is absolutely necessary, and after a good watering on the surface, the water in the saucer should be poured off. In order to secure a constant and equable degree of moisture to lightly covered seeds, they should be covered, until they germinate, with a bell-glass, or with a pane of glass, or with a piece of thin paper. In using the glass or paper there should be a space of at least one-third of an inch between it and the surface of the soil in the pot. The bell-glasses or panes of glass should be removed every day and cleaned. The state of the soil can then be examined, and water given if required. As soon as the plants begin to come up, the glass coverings should be removed altogether. The daily removal of the glass for the purpose of cleaning is also useful in admitting a fresh supply of air, and preventing the drip of condensed moisture. To the tyro in plant culture we strongly recommend, when he is in doubt, either not to cover at all or only very lightly, and for this purpose a piece of thin paper is the best. He must remember to remove it altogether as soon as the young plants appear. Too thick a covering often hinders small but perfectly fresh and sound seeds from germinating.—*Dr. Regel.*

(To be continued.)

TABLE DECORATIONS.

THERE is no better judge of these than Mr. Thomson, and I think he will agree with me that it is equally as difficult for parties to get up good tables as it is for judges to arrive at proper decisions respecting them. In the first place, parties who get up a table have no chance of realising that perfection which a good house steward can effect, after a little consideration as to the number of lights, amount of fruit, sweets, &c. These all combine to make a whole that a competitor for a prize is deficient in, and this filling in can only be done by a very practised eye. Again, there is the difficulty of variety. It is puzzling to effect a change, and if table decoration is real, as it is with us, it means flowers, &c., at every meal. We have to study to prevent sameness. We could pass a table without fruit, but not one

without flowers; and this demand for variety suggested the idea of putting pots under the table, and using at first some beautiful standard azaleas, fuchsias, &c.; and, notwithstanding what has been said in the *Telegraph*, I know nothing more beautiful than a fine head of an azalea rising from the table so as to make a perfect little mound of bloom without any unsightly vase or covered pot to mar the floral effect. A high palm also looks well. At the same time I do not think the first prize at Kensington came up to the mark, as the ferns were not improved by being put through the table. There is not the least necessity for lighting up exhibitions of table decorations, for any one in practice can tell in a moment what produces the best effect.

I must, after all my practice, agree with my noble employer in thinking that there is nothing better than flowers. Palms, Ferns, and Lycopods are all black by night, and should only be used for the side table. Nothing lightens up like flowers in low contrivances of different devices. I would not even have orchids, or any plants growing in pots; nothing scarcely but common English or alpine and herbaceous flowers—those little friends with which all are familiar. These add a cheerful harmony and charm to a table properly arranged that no ungainly orchid or other pot plant can ever give. At the same time, anyone conversant with the arrangement of a table would know how easy it is to put slips in; besides, most dining-tables are now made of common deal, which nobody sees.

J. FLEMING, Gardener to the Marquis of Westminster, Cliveden.

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from p. 155.)

TERMINAL CLEFT-GRAFTING.

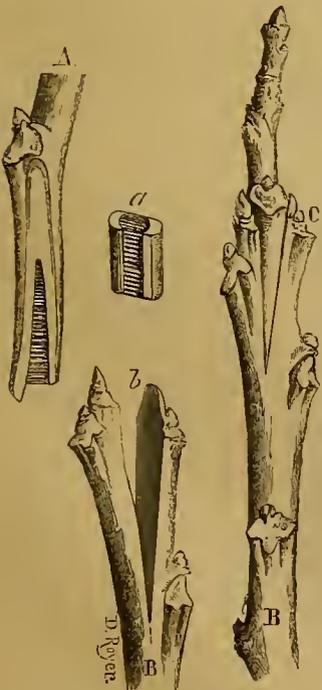

THE modes of cleft-grafting which have been described are only terminal in a certain sense. In those which follow, the grafts are more especially applied to the top of a stock not headed down, and are inserted with a terminal eye.

TERMINAL WOODY GRAFTING.—The season for performing this operation is in spring, before the flow of the sap. We have employed this method with the walnut-tree and the fir.

TERMINAL GRAFTING OF THE WALNUT-TREE.—The scion (A, see fig.) is cut with a regular double slope (a); the stock (B,

is cleft in the middle of its terminal bud, moderately, so that the introduction of the scion may complete it. The stock and scion are then bound firmly together with a bandage at the top and bottom of the cleft, and the tying is allowed to remain until the scion begins to sprout. At this period, the shoots of the stock are to be pinched, but not cut off altogether. They will continue to draw the sap towards the graft. This kind of grafting has succeeded better with us under glass than in the open air; however, we have thought it better to mention it, as it has succeeded with the air excluded, and also because it may be tried on other plants.

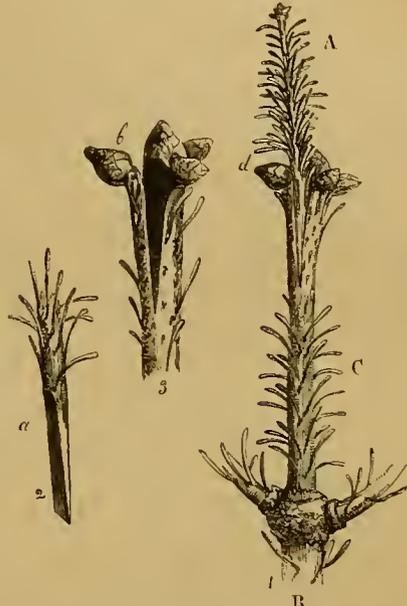

TERMINAL GRAFTING OF THE PINE.—The varieties of the Pine, Piceas, Abies, &c., of which the stem increases every year by a whorl of branches and a leading shoot not branched, may be propagated by means of this method, which is practised in the

Terminal Grafting of the Walnut Tree.

open air in April and May, when the buds of the Pine begin to swell. The scion (A), taken from the top of a branch, is a shoot of the preceding year crowned with its terminal buds. It is cut on

both sides in a slightly slanting direction, as at *a*, and introduced into the top of the shoot (c) of the stock (B) in a longitudinal cleft made between two buds of the crown at their junction near the central bud; this cleft may be partial or entire (*b*). The insertion having been made (as at *d*), it is bandaged with wool or cotton and covered with mastic; the graft is then surrounded with a leaf of paper, in order to preserve it, when it begins to sprout, from the action of the sun and hot winds. At the same time the shoots of the upper whorl of the stock, are cut to half their length; the slender ones may be bent downwards. The object of this precaution is to divert a larger supply of sap to the graft. No part of the

Terminal Grafting of the Pine.

stock except the upper whorl is to be thus cut. Even afterwards the branches of the stock must not be too closely pruned. If they extend too much, a moderate pinching in summer will suffice to check them. The stock may be grafted at any age, and either in the open air or under glass with the air excluded. The trees which result from this mode of grafting will have all the appearance of having been raised from seed. Of course, it will be better to graft them when young, if a longer enjoyment of their habit and foliage is desired. In the nurseries about Metz, this mode of grafting is successfully practised in the open air, in July and August, when the scion and the leading shoot of the stock are passing from the herbaceous to the woody state, and present sufficient consistence to allow of this mode of grafting being performed.

TERMINAL HERBACEOUS GRAFTING.—We have used this method chiefly with the pine, but we have every reason to believe that it will answer other members of the Conifer family equally well. When the sap first begins to flow in May and June, and the young shoots of the pine are already an inch or two long, and before the new leaves are developed, is the proper time for grafting. The scion (c) is one of these young shoots in an almost rudimentary state, with a bud at its extremity; it is taken from a branch of the parent tree, it does not matter whether from the top or the sides. It is cut with a sharp knife on both sides, in an even sloping direction. This must be carefully done, on account of the delicate texture of the wood. The stock is cut off at the top of the leading shoot, immediately below the group of terminal buds. The leaves around the top (B) are removed, except a few which are left to attract the flow of the sap. The cleft is made either right across

Terminal Herbaceous Grafting.

the top (B) are removed, except a few which are left to attract the flow of the sap. The cleft is made either right across

or partially, according to the difference between the diameter of the stock and that of the scion. The scion is inserted rather deeply into this cleft so that the top of the cut part may be a little below the level of the top of the stock, and the bark should coincide with that of the stock on one side at least. A prop or a stake will be necessary to support the graft for a year or two. It is bandaged with wool, and the cuts exposed to the air must be covered with mastic; a paper cap is placed over the graft and kept there until the scion has begun to sprout. The stock will not afterwards require any clipping, disbudding, or pinching of its branches. The Forest of Fontainebleau affords examples of *Pinus Laricio* which were thus grafted on *Pinus sylvestris* forty years ago, and the trees are as fine as if they had been raised from seed. For twenty years past, M. Jules Barotte, of Brachay (Haute-Marne) has converted by this method thousands of *Pinus sylvestris* into *P. austriaca* and *P. Laricio*. He operates in the open ground or in the forest, grafts the subjects on the young leading shoots at the height of two or three feet from the ground, and never covers his grafts with paper caps, as they do in the nurseries.—*C. Baltet.*

(To be continued.)

Lilies from Seed.—My practice is to sow the seeds as soon as ripe in frames or in the open ground in boxes with open bottoms, across which a few laths are nailed. The boxes being plunged in the soil, these laths prevent their being thrown out by the frost, allow the moisture to rise from below, (thus obviating the necessity of watering, which is liable in this instance to do more injury than good), permit the roots to feed in the fertile soil placed under the boxes, and hold in place the bulbs in the boxes, if it is ever necessary to move them. The frames or boxes are supplied with light sandy soil, with which leaf mould or peat has been freely mixed. Though a few plants may appear during the next summer after sowing, I do not look for the seed to start till the second spring, eighteen or twenty months from sowing. The little bulbs should remain undisturbed two years or more.—*C. G. P.*

NOTES AND QUESTIONS ON PROPAGATING.

Striking Cuttings in Wardian Cases.—It is probably not generally known that cuttings of many kinds of plants not usually increased with facility by amateurs, may be rooted easily in a Wardian case in the sitting-room. I have just seen several of the simplest kinds of these cases filled with nicely rooted little plants of Conifers, Hollies, and various other choice evergreens, in Mr. Cook's studio, at Glen Andrew.—*W. R.*

Propagating the Dieffenbachia.—The practice generally adopted is to cut down those plants that have become too tall to look pleasing, using the top for a cutting, and dividing the stem into as many parts as there are joints; these joints are then inserted in sand or other light material, allowing them the advantage of a gentle bottom heat. This, though a successful method, is, as far as certainty and the procuring of strong plants are concerned, superseded by the following:—Having ripened the plants well in autumn, and allowed them a little rest in winter, start them towards the end of February in bottom heat, with an atmospheric temperature of 60° or 65°, and supply them with water rather carefully at first, but copiously when they show signs of active growth. As soon as they have fairly started, take off the top and use it as a cutting, still retaining the old stump as it was. The ascending sap finding itself thus checked, stimulates the dormant eyes and forces the uppermost one to push forward and take the lead. This, when sufficiently advanced, should be taken off the parent stump, retaining at its base a piece of the old wood. By inserting this, and treating it as a cutting, a new plant is produced much sooner, and of a stronger constitution, than by the ordinary method. Nor is the old stem then rendered useless, for, finding itself deprived of its top shoot, the next bud takes the lead; this in its turn is treated as its predecessor, until every eye upon the stem is utilized.

Cleaning Walks with Acids.—There seems to be some misunderstanding on the subject of cleaning walks by means of chemicals, and of acids in particular. One correspondent recommends hydrochloric acid, another sulphuric. Now neither of these need be used in a pure state—indeed it is wasteful to do so. In using pure hydrochloric acid, there is a danger of killing the foliage in the vicinity by its strong fumes, which are the most deadly to vegetation of any known, but this danger is over in an hour when the acid is neutralised by its distribution in the gravel. Its cost is greater than that of sulphuric acid, and it will not act well if diluted with more than five or six times its weight of water. Sulphuric acid, on the contrary, makes no fumes, and therefore will not harm in that way; it is a stronger acid and will bear three times as much diluting without losing its pungency; it is also cheaper, being obtainable for about 1d. or 1½d. per pound by the carboy of one cwt. Spring is the best time to apply it, also dry weather, else it gets washed away. Dilute it with fifteen or twenty times its weight of water, and lay on just enough to wet the surface, being careful not to splash it.—*A. DAWSON.*

KEW GARDENS AND THEIR MANAGEMENT.

Your article of the 10th inst., in reference to these gardens, was as full of truth as many we have read lately in other journals have been of error. The purpose of Kew should be that of introducing new plants, and testing their value, teaching the public in matters horticultural, and exhibiting for their instruction specimens of all classes of plants, be they beautiful or not so. Now is Kew doing this? Let us see; in the Botanic Gardens, properly so called, instead of finding specimens of all kinds of hardy shrubs, we find large beds of common Laurel and Rhododendrons. The collections are put out in the pleasure grounds; in the houses we find plants exhibited so as to show the public how they do not grow. Where are the interesting Pitcher plants, like those one sees in such luxuriance at Messrs. Veitch's? Where are the grand old plants of Banksias and Dryandras that used to be a feature of Kew? If we look for a specimen of rockwork, we find a slight modification of a stone wall. If we look for beauty of landscape, we find vistas large and vistas small, giving the place the appearance of having been laid out for the convenience of rabbit shooters. If we look for examples of tree planting, we find thousands of small ones planted under the dense shade of large Beeches, disfiguring the scene, and doomed to die or grow like hop-poles. Is this scientific? It has long been known that trees planted under the shade of others will never do any good; therefore such planting cannot be an experiment. It has been said that the late and present director have brought the gardens to what they are, which is quite true; though it appears that the object of the present one is to undo all that the late one did; for it is notorious that he has been cutting down trees and shrubs, or transplanting them, until we have the majority of the trees of the Pinetum moved. And where are they? Echo answers "Where are they?" Most of the fine shrubs which used to adorn the Botanic Gardens have been grubbed up, burnt, and replaced by a quantity of common Laurels, &c. We have seen a vain attempt to make a lake out of a duck-pond, though why a lake should be wanted within a few yards of one of the finest bends in the whole length of the River Thames has been a matter of surprise to many. We have heard much about "scientific" management lately; in fact it has almost become a party cry. Well, what does it mean, this great word Science? Here we have it: "Knowledge reduced to a system;" and truly it is. But we have had knowledge reduced to system long enough; it is now quite time that systems were reduced to knowledge. We have had many gardeners writing lately in favour of Kew continuing under the old system of management; but what would one of these say if he was told by a man who had never looked after a house of plants in his life, when to water his plants; or find himself told to keep a house of Ferns dry as a bone for a month, the same with stove plants, and hard-wooded Australian plants (even when standing over hot pipes), and his men threatened with dismissal if they gave them water? Or having to raise seedlings and cuttings of all sorts of tender plants without anything but clayey loam and sand to pot them in for three months, and on speaking about it to be told by such a person that that description of soil was best for them (he being held responsible for their culture)? Again, let him go into a house of plants for which he was held responsible, and finding many suffering from want of water, on mentioning it to his assistant, find he had been ordered by the director, or his head foreman (who at Kew is called curator), to keep them dry? How would these writers like such a position? And yet this is what is done at Kew, and what they unconsciously wish to be continued; but what no friend to Kew can possibly wish to see maintained for a single day.

J. CROUCHER, (late General Indoor Foreman, at Kew).

ALLOTMENT GARDENS.

STATEMENTS have been made that the number of professional gardeners exceeds seventy-five thousand, but for one professional gardener there must be a hundred amateurs. Those who, like myself, have visited some of the suburbs of manufacturing towns, can alone form an idea of the vast numbers who, recognizing the truth of the old saying "change of work is a holiday," rush from their daily employment to their little gardens, and often work harder there than they have done all day. It has been asserted in a garden paper that there are no less than five thousand gardens round Nottingham, and we may assume it is true. If we could but calculate the number of hours thus rescued from the public-house, how anxious we should be to afford, round every town and village in the kingdom, the means of employing every poor man's leisure hours in this way. It has been said property has its rights; but it has also its duties, and one of its duties is that of studying the welfare of its dependents. I should like to see some of the many spare acres divided into allotments, to be held by working men, not at an extortionate rent. Round Sheffield the price of a bit of garden is

enormous, and there are rich noblemen who could afford to lower the price by devoting some land to allotments at the current farming rent, and thus employ men who have nothing to do in their spare hours, and rush anywhere for society. I have been told that land in the neighbourhood of Sheffield lets at four shillings and sixpence the square rod, of which there are one hundred and sixty in an acre. That would average thirty-six pounds per acre, amounting to exclusion, except for the better class of tradesmen. The poor are as completely shut out as if there was no land, yet thousands of allotments could be made, and much of the time now lost in the public-house would be saved. Let me plead for the industrious classes with those wealthy landowners in the hope that they will speedily let some portion of their estates for garden purposes. Depend on it an awful responsibility rests on those who can redeem the idler, and improve the moral and social condition of the poor, and neglect to do it. Now I know, from over forty years' experience, that allotments and prize shows for exhibiting the produce, have so improved the population in some towns that persons, like myself, who had not visited them for several years, and knew them only at their worst, considered the change next to a miracle. In 1851, I was gardener at Pusey House, in Berkshire. My employer sent over four hundred of his cottage tenants to the Great Exhibition. Most of these poor cottagers had a quarter of an acre of land. I hope there will be more of this consideration for the poor; that the rich will see the necessity of placing in the poor man's way the means of spending his leisure hours profitably; for it is a hard case that men should have no choice between solitary idleness and the excitement and expense of the alehouse.

Notting Hill.

WILLIAM GILES.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.

PRIVATE GARDENS.

Conservatories.—Camellias, the finer kinds of Rhododendron, Orange trees, and cool-house Palms, are being thoroughly washed, so as to set them right for autumn and winter. Tree Ferns are now being watered freely, especially such as are in borders, care being taken, however, not to give so much as would render the drainage imperfect. Cannas in pots, when placed, as they begin to flower, amongst evergreen shrubs, produce a cheerful effect, and the presence of Japan and other Lilies also greatly aids indoor decoration. Gladioli grown and bloomed in pots are also used advantageously in the same way. Vallotas, when placed along the fronts of conservatory borders as they come into bloom, and plunged so as to hide the pots, form nice companions to *Moræa iridioides*, Hydrangeas, African Lilies, dwarf Fuchsias, and such plants as are commonly used for border decoration. Where there are large Palms, Bromeliaceous plants may often be seen on their stems, set in moist peat, resting on the base of some decayed leaf-stalk. These, when in good condition and well supplied with moisture, give the Palm stems a dressy appearance. In shaggy-stemmed sorts, such as those belonging to the genus *Phoenix*, no soil is used, and yet many Bromeliaceous plants there well if kept moist. Herbaceous kinds of Begonia, such as *Sedeni*, *intermedia*, *Bolivienensis*, *maritima*, and others, form lovely objects at present in conservatories. These occupy positions well sheltered, cold draughts being detrimental to them.

Stoves.—Stove plants which are growing freely are now encouraged to ripen their wood, for on that depends their future welfare. *Eucharis amazonica* is now producing flower-spikes in abundance; a smart bottom-heat, a brisk atmospheric temperature, plenty of moisture, and open rich material to grow in, are what it delights in, and it always blooms best when the pots or tubs in which it is grown are well filled with young and healthy roots. *Pentas carnea* also forms a conspicuous plant in stoves at present; its only fault is being subject to mealy bug, which insinuates itself amongst its flower buds as it does amongst those of *Ixoras*, and the only means of eradicating it is patient washing and brushing it off, using for the purpose water in which a little soft soap has been dissolved. Aquatic plants, such as *Nymphaea cærulea*, *gigantea*, and *devoniensis*, and *Nelumbium speciosum* now require a little attention. The tank in which they are grown must never be filled up with anything but tepid water. The *Nelumbium* requires a less depth of water than the *Nymphaeas*, but a greater depth and extent of soil; indeed, it does best when planted in a compost of three parts good turfy loam and one of leaf-mould with some sharp sand. The *Nymphaeas* are generally kept in pots placed on inverted pots in the bottom of the tank. Amongst stove creepers none are more effective at present than *Cissus discolor*, especially when grown in a warm, moist, partially shaded house. As finely coloured leaves as I ever saw on

this *Cissus* were produced on a plant in a fernery, in which the roots were so situated as to receive a little bottom heat. Thus circumstanced, it keeps in beautiful condition summer and winter, and in every succeeding summer it sends forth its shoots more vigorously than before. As a companion to ferns, *Philodendron Lindenii* is a suitable plant, for when a little shaded it rambles over mossy stones, and its fine glossy leaves are very effective. *Marcgravia*, too, cling to wood or stone, and thrive luxuriantly in moist heat, just as well as the *Ivies* do on old walls. With these might also be associated the *Æschynanthus*, the different kinds of which are very pretty.

The Flower Garden.—The moist season which we have had has induced plants to make fine growth, but as regards display of bloom it is not so good as usual, and it has also been a good deal damaged by rains. On the other hand, herbaceous plants are better this year than they have been for many years past. Phloxes especially are particularly fine. Pentstemons have also been unexceptionally good, but they are now almost over. On these two classes of plants the rain has had no ill effects. Conspicuous among other fine things is *Amarantus salicifolius*, now a lovely object; it is beginning to assume a colour somewhat similar to that of *Alternanthera amœna* when grown in poor soil; high colouring, indeed, can scarcely be expected in rich ground in which the plants are stimulated into unusually robust growth. Other *Amarantuses* also form conspicuous objects, the kinds called bicolor and tricolor being useful as ground-work to Castor-oil plants, and other plants of similar appearance; they also make nice little beds of themselves. *A. melancholicus* when pinched in or pegged down makes an excellent dark panel: even *Love-lies-bleeding*, when well grown and mixed with sub-tropical plants, has a good appearance, its long pendent flower-spikes being always attractive. *Alternantheras* this year are particularly fine; they always grow and colour best when a little peat is mixed with the soil. The best kinds are *amœna*, *magnifica*, *paronychioides*, and *versicolor*. *Coleus Verschaffeltii* is another useful dark-leaved plant, which gives much more satisfaction when a little peat soil is mixed with the compost in which it is planted. Flower-spikes of the *Yuccas*, as they become decayed, should be removed. The prunings of the variegated *Thyme* and similar plants are being used for purposes of propagation. The arrangement of bedding plants for next year is being made, and the plants to be used decided upon. This is a matter which is much more easily settled now than at any other time. Where trees and shrubs are intended to be transplanted, their places are now marked out, and any other alterations to be done in the winter months are being decided upon.

Indoor Fruit Department.—The leaves of Vines in the earliest houses are now assuming a yellowish tinge, and the wood is quite hard and well browned. Vines in pots are now set as near the glass as possible, in order to encourage them to ripen. Melons that were planted a few weeks ago are encouraged to make growth by means of a brisk bottom heat. Cucumber beds are kept well watered, and if necessary, top-dressed. By means of steady and judicious thinning, the bearing season may be considerably lengthened. Tomatoes are kept in houses or pits as near the glass as possible, so as to get their fruit well ripened. Should the roots become pot-bound, a little manure water is given.

Mushroom Beds.—These are being formed, both in houses set apart for them and in out-houses or sheds that can be kept dark, and where the temperature will never be likely to fall below 45° nor rise above 70°. In making up the beds, the rankest of the litter is separated from the rest and is placed aside, so that only the shortest litter is kept for the bed, and with this a little light soil is mixed. The whole is then spread out on the floor of a dry shed, and added to as circumstances permit, keeping the whole in a mild fermenting condition by frequent turnings. As soon as sufficient manure is got together to form the beds, they are made mostly on the flat system, that is, not in the form of a ridge; and as soon as the strong heat generated declines to about 80° or 85°, the beds may be safely spawned. Those made in the end of last month are being spawned now.

Outdoor Fruit and Kitchen Garden Department.—Lime is being strewed over the Cabbage beds sown some days since. Borecole, and the latest crops of Broccoli, are being planted out on ground from which Potatoes have been lifted. A few Cardoons are being bound round with hay or straw, and earthed up for blanching. The first main crop of Celery is being earthed up. In doing this a piece of matting is tied rather loosely round the leaves, so as to keep the soil from getting into the hearts of the plants, and then the earth is worked round the plants, not giving too much at once. Another way, and that usually adopted where two or three rows are grown in each ridge, is to have a man or boy to hold up the leaves of each plant with one hand, and with the other to work the soil around the stems. This is not nearly so tedious an operation as might be imagined; a

little lime is dusted over and about the plants, to prevent damage from slugs. The suckers, as they appear about the necks of Celeriac, are removed. Late sowings of Turnips are being thinned. A bed of Radishes, where not done earlier, is being sown. Garlic and Shallots are taken up and dried in the sun, taking care to protect them from rain. The main sowing of Onions for standing through the winter has been made this week in early localities, or where the soil is light; the main sowing, when the soil is inclined to be cold or heavy, was made on or about the first of the previous week. A piece of ground is being got ready for the last sowing of Spinach. A sowing of Cauliflowers where they can be protected throughout the winter has been made. Endive is being planted out on warm sunny slopes; plants fit for use are tied up or covered so as to cause them to blanch. American Cress and Corn Salad are sown for winter use. As soon as the seeds of Angelica are ripe, they are also sown. Small sowings of Mustard and Cress continue to be made at short intervals.

NURSERIES.

Indoor Department.—In nurseries, plants of which a good stock is required are grown on in winter as well as in summer, potted and propagated as opportunity affords, and maintained in activity by means of a strong moist heat compared with that commonly given to plants during the dull season. The propagation of bedding plants occupies considerable attention at present. Young plants of *Primula sinensis* are being potted into three-inch pots, using a compost of good yellow loam two parts, and one of leaf-mould or well decayed manure, and a fair quantity of sharp river sand. The plants are then placed in cool airy pits, the sashes of which are kept shut for a few days, and the plants are also closely shaded. Seedlings of *Primula japonica* are being shifted, some from the seed-pans into three-inch pots, and others, earlier shifted, are being repotted into forty-eight-sized pots and placed on beds of ashes out of doors. Auriculas are being repotted and placed in frames with a north aspect. Petunias are being increased from cuttings in gentle heat, and as soon as rooted are shifted singly into small pots and placed on raised boards in cold frames. Pinks for forcing are being potted; cuttings are freely exposed to air, but shaded from too bright sunshine. Neapolitan Violets are being lifted and potted for forcing. Single red Camellias are being propagated by means of cuttings in a very gentle heat; these will be hereafter used for stocks for grafting on. The grafting of Camellias and different kinds of Citrons and Daphnes is being done in pits and the plants are kept under hand-lights and well shaded. Conifers, in the way of the finer kinds of *Thuja*s, *Abies*, &c., are being increased by means of cuttings made either entirely of the young wood or of the young wood with a heel of old wood attached to it. They are then inserted in six-inch pots filled with light peaty soil, nearly half an inch of the surface being pure silver sand. These pots are then plunged in cocoa-nut fibre under hand-lights, which are kept in cool pits and densely shaded. Roses are being propagated by means of cuttings in frames or under hand-lights in a warm border. Clematises that have been layered are being potted, as are also the rooted pieces of layered Japanese Maples.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

(AUGUST 21st.)

At this meeting Gladioli formed the chief feature, and to some of the new kinds exhibited first-class certificates were awarded, the sorts to which they were given being a decided improvement on kinds already in cultivation. Many old sorts were also shown in fine condition, more particularly Norma, which in one instance we do not remember ever seeing finer. Amongst the best of the others were Horace Vernet, Virgile, Meyerheer, Adolphe Broignart, Lapepède, Orpheus, John Standish, Sulphureus, Mathilde de Landevoisen, and M. Desportes. The principal exhibitors in this class were Messrs. J. Standish & Co., Ascot; Messrs. Kelway & Son, Langport, Somerset; and Mr. J. Douglas, Loxford Hall, Ilford. Hollyhocks were also very fine, both in the form of cut flowers and spikes. Some from Lord Hawke were excellent; as was also a large collection from Mr. Chater, Saffron Walden. There was a stand of as fine double Zinnia blooms from Mr. J. Chater, Gonville Nurseries, Cambridge, as we have seen. This was deservedly awarded a cultural commendation. The same exhibitor showed some stands of very large-bloomed Asters. Cut spikes of Phloxes were exhibited, but they were somewhat past their best; still, a stand from Mr. J. Chater contained some very fine sorts. The best, however, came from Mr. R. Parker, Tooting, who also showed a dozen herbaceous plants in pots. A basket of *Vallota purpurea*, lighter in colour than we commonly see it, was shown by Mr. Standish, who also exhibited that useful little summer-blooming plant *Bouvardia Vreelandii*, and *Nerine Fothergilli*, finely in flower. By far the best feature of the show was, however, the fine Nepenthes *Rafflesiana* from Mr. T. Baines, of Southgate, referred to in another column.

This was shown in a pot raised some distance above the stage, so as to permit the pitchers to hang at full length. Mr. Baines says that a very common cause of failure in growing this plant is keeping it in too moist and stagnant an atmosphere. It loves heat and moisture, but at the same time it must have abundance of light and a free circulation of air. He says young plants always form pitchers larger and better than old ones, and that such a place as a Cucumber pit, where heat and air are always at command, and the plants kept near the glass and well watered, is as good a place for this plant as any other that could be selected. There was a small collection of Orchids from Messrs. Veitch & Son, Chelsea. Although late in the season, *Phalænopsis amabilis* and *Odontoglossum Alexandræ* were very fine; there were also the beautiful little *Mesospidium vulcanicum*, a lovely-flowered specimen of *Dendrobium chrysotes*, and a few others. The same firm also showed some exceedingly well-coloured plants of *Amarantus salicifolius*, that had been grown for the last ten weeks in the open air. From the Society's Garden at Chiswick likewise came examples of the same plant, that had been grown in pots out of doors, but which were not so well coloured as those from Chelsea. This fine *Amaranth* never colours so well indoors as out; poor soil, and free exposure to air are what it requires in order to have it in perfection. Of Fruits and Vegetables there were but few; nor did they present anything new. French Beans and Runner Beans were good.

First-class Certificates.—Certificates were awarded to *Gladiolus Helorus*, *Osci*, *Lycoris*, *Lamirus*, and *Orchus*, from Messrs. Kelway & Son.

To *Gladiolus Rosy Morn*, *Gwendoline Morgan*, and *Day Dream*, from Mr. J. Douglas, Loxford Hall, Ilford.

To *Dahlia James Service*, a dark brown excellent flower; *Rev. J. M. Camm*, a good striped kind, the ground colour being yellow striped with brown; and to *Ne plus ultra*, a fine black-coloured sort, all from Mr. J. Keynes, Salisbury.

To *Lælia elegans Marshallæ*, a purple-coloured kind, from Mr. Wilson, gardener to W. Marshall, Esq., Enfield.

To *Phlox Heynholdii*, a dwarf orange-red flowered kind, a good addition to varieties of *P. Drummondii*, from the Society's Garden, Chiswick.

To *Fuchsia Delight*, the corolla of which is large and white, the tube and sepals deep red.

To *Lilium tigrinum*, var. *Lishmauni*, a fine form of Tiger Lily, with splendidly spotted petals. Though in several respects distinct from the ordinary Tiger Lily, it is, however, nothing more than a mere variety of that kind.

To Duke of Buccleuch Grape, exhibited at the last Meeting by Mr. Wm. Thomson, Clovenfords, Galashiels.

The New Grape, Duke of Buccleuch.—Mr. Barron read the following report of his investigation of this Grape, raised by Mr. Thomson:—"In accordance with instructions, I visited Clovenfords last week and saw this Vine growing there. Mr. Thomson has it planted pretty extensively—1st, twenty-two Vines in one house, at six feet apart, two rods to each Vine, the rest of the house being filled with Black Hamburg, Golden Champion, and other sorts; 2nd, about forty Vines on either side of a span-roofed house at nine feet apart, three rods to each Vine, the rest of the house being filled with Muscats, Golden Champion, &c. The whole of these Vines were planted in the autumn of 1870. The greater portion of the crop (300 lbs.), had been cut previous to my visit. There were still, however, about 250 bunches hanging, which enabled me to arrive at a pretty good idea of its bearing qualities. There was a singular uniformity in the appearance of the whole, both as regards the growth of the plants, general productiveness, size, colour, and general appearance of the bunches and berries. In growth it somewhat resembles Canon Hall Muscat, Mill Hill Hamburg, and Golden Champion, the shoots being rather gross, and in some instances not ripening berries thoroughly. Generally, however, the wood was well ripened, the leading shoots being very strong and thoroughly ripened, of about the thickness of one's thumb. I could detect no spot or other blemish on the berries; whereas the Golden Champion alongside, although large and well-grown, was much spotted. As to ripening, in comparison with the Black Hamburg grown in the same house under the same circumstances, it was much earlier—evidently some weeks. Few of the Hamburgs were ripe or fit to cut, whereas the most of the Duke had been cut and sent to market a month previously. The Hamburgs were, however, overcropped, which tends to retard the ripening. The Muscats under the same treatment had not begun to colour, whilst the Duke was dead ripe; and at Drumlanrig, the Muscats being ripe, the Duke was quite overripe and spoiled. Golden Champion, also, by comparison, was quite green and acid. At Clovenfords and at Drumlanrig each Vine of this variety seemed to have fruited as freely as a Black Hamburg, one bunch to each spur; the bunches being of a fair average size of from one to two pounds each, and some larger. Grafted on the Muscat it did not seem to do so well; in one instance the fruit was much greener and later, and in another it had not set regularly, some berries being enormously large, and the rest small. The Duke of Buccleuch is a Grape which will evidently not keep long after being ripe, being thin-skinned. It is extremely pleasant to eat, the flesh tender and juicy, with a rich sparkling acidity, somewhat of the Hamburg character. The berries are enormously large, round or oblate like the Dutch Hamburg, and have rarely more than two seeds in each. I should describe it as a very valuable summer Grape."

A CONVERSATION at Holland House turning upon first love, Tom Moore compared it to a potato "because it shoots from the eyes." "Or rather (exclaimed Byron), because it becomes all the less by pairing."

THE GARDEN.

—o—o—o—
 "This is an art

Which does mend nature: change it rather: but
 THE ART ITSELF IS NATURE."—*Shakespeare.*

BATTERSEA PARK IN 1872.

LOVERS of flower gardening look to Battersea Park with somewhat of the interest that lovers of pictures feel in the Academy. This has been so ever since Mr. Gibson introduced the stately foliage-plants into the flower garden there, and it is likely to continue, we are glad to say, as long as his successor remains at Battersea. It might occur to some that the very remarkable gardening there would suffer on its introducer being called away to take charge of another park. We are glad to say that, so far from this being the case, improvement is going on rapidly; that the garden never presented more novelty than at the present time, and that, notwithstanding the peculiarly late and severe season, the foliage-plants are in fine condition. We moreover noticed certain important changes, which appeared to us to lead in the true direction. In old times, one of the least agreeable features of the park were the tedious interminable lines of *Stachys* and red *Pelargoniums*, which fringed every shrubbery and plantation with a formal glare. Mr. Rogers has, we think very judiciously, done away with a great many of these, has broken the margins of the shrubberies, where too formal, by projecting shrubs and plants of some interest and character here and there, and by causing the turf to creep over the wide formal borders and under the shrubs and trees. Most admirable, however, among the changes is that of reducing the over-lavish effect produced by too great a profusion of beds in one place. A good example of this may be seen at "The Cottage," which was always agreeably surrounded by flowers, but which, in consequence of a judicious reduction of the beds, is prettier than ever this year. At the same place, and between each bed of flowers, may be noticed a little group of Palms, *Dracænas*, &c., plunged in the grass in the most quaint and charming way. And this reminds us that the in every way admirable system of grouping and isolating remarkable looking plants on the turf, is carried out by Mr. Rogers to a very large extent, and with a taste that we have never seen surpassed in gardens. Palms, *Yuccas*, and succulents are neatly plunged in the closely-shaven turf in natural looking groups, so that they at once strike the eye, while they are fully exposed to the sun, and are not shaded or otherwise injured by neighbouring subjects. In the case of all hardy plants, this system will be found an immense improvement, as it not only shows the plants to the best advantage, but gives them a chance of growing to their fullest perfection, which they never had under the old or common system of huddling everything together in a shrubbery or mixed border. It also admits of an infinite variety in arrangement. The mixed system has also been introduced with a very happy effect. At one time, and indeed mostly as yet, the beds of fine-leaved plants were of one kind, with perhaps a belt or edging of some other fine-leaved subject. While such beds certainly relieve masses of bright colour, it is a great mistake to suppose that they were any more than a step on the way to a more beautiful system, and that is the mixed one. Not anything like the mixed border, however, but artistic groupings of fine-leaved and flowering plants so combined as to "bring out," so to speak, each other's beauty. A beginning only has been made in this great improvement at Battersea, but every step taken in the matter by Mr. Rogers proves its great merits. When we consider the various fine flowering plants, such as the Lillies, *Gladioli*, and *Dahlias*, that are well adapted for close association with the fine-leaved plants, it is easy to imagine what beautiful and infinitely varied results may be obtained in this way. Even in grouping the fine-leaved plants themselves, much may be done by the mixed system; one of the most admired beds at Battersea this season has the central group of *Cannas* surrounded and beautifully relieved by tall plants of the variegated *Maize*, and finished off with a few smaller subjects towards the

edge. Nothing can be neater than the succulent bedding at Battersea Park this year; still more effective and right in direction is the way in which little groups of quaint-looking succulents are boldly distributed on the turf in an irregular manner. The mosaic beds of dwarf *Alternantheras*, &c., are very neatly done, and when viewed close at hand suggest that much skill and pains have been bestowed upon them, but nothing more. A little way off they look like carpets, but carpets such as nobody has had the hardihood to offer for sale for many years past. But if they resembled the finest carpets ever woven by man they should, notwithstanding the Rev. Mr. Peach's opinion, not command our admiration. He who says, or thinks, that a garden should in any conceivable sense resemble any carpet yet seen, has still to learn in what consists the true pleasure of a garden—a simple but essential lesson that many a cottage garden teaches. The extensive and noble rock-garden made by Mr. Gibson has been well planted by Mr. Rogers, and a charming hardy fernery constructed near it, which, although planted last spring, is already quite a picture.

Having pointed out what seem to us improvements, it may not be amiss to indicate to the amateur visitor a few defects that he would do well not to copy—defects which it is very likely a few years more will see entirely removed. Most evident is the *embarras* of riches which occurs near the serpentine beds in the sub-tropical garden and in a few places along the walks which lead from it. The finest effects are weakened or neutralised by being multiplied without end. These serpentine beds themselves are quite out of place in such a sweetly natural looking garden as this is in many parts. To the long formal beds the same remark will apply. Some day will see us as anxious to conceal the shape of the beds as we are now proud to expose bold geometrical forms among them, and this because, in the best type of garden, every beauty depends on what is in the beds, but none whatever on the shape of the beds themselves. We could instance some beautiful garden scenes where there are no beds visible, and, though beds are indispensable, it is better in the naturally disposed garden to have them as simple in form as may be convenient. The sharp-edged banks and beds, mounted on stiff mounds, are also very objectionable as seen at Battersea. We miss in them the quiet and exquisite gradation of line, and the gentle moulding of the turf, which are seen so fully in such places as Berry Hill, Oak Lodge, Kensington, and at Mr. W. H. Smith's place at Henley-on-Thames. Many of these flaws it will take a good deal of time and labour to remove, and we merely point them out that visitors may not imitate them. On the whole, however, the gardening at Battersea is admirable, and highly instructive. The sub-tropical garden there may be safely pronounced the highest example of flower-gardening that exists at present, and, if nothing else came to the rescue, would suffice to break the back of the ugly monster, "Bedding-out." With such a noble example before us, those who have hitherto won some glory from outblazing their neighbours, and now grumble greatly because this glory is departing from them to those who better deserve it, may preach against the new movement and grumble on in vain. To Mr. Gibson, the very able, courteous, and modest superintendent of Hyde Park, must always belong the credit of creating Battersea Park, so to say; and, happily for the art of gardening, he has been succeeded by one who clearly sees, and steadily works for, its highest interests.

WHENCE COME THE FINEST ROSES?

THE Rev. Mr. Camm and Mr. Baker, two earnest and clever rosarians, having expressed their dissent from my opinion, that the best Roses, as a rule, were produced from the Briar, I have consulted the six most successful Rose growers of England, and have been favoured with their experience on the subject.

In the year 1871, Mr. George Paul, of the Old Nurseries, Cheshunt, took the principal prizes at the great Rose shows. In that year, he informs me, "the Roses from the Briar were the finest and largest." In the present summer, when his Manetti Roses were the best, he appeared only once in the

champion's place. In his reply to my inquiries, he adds, "the Briar mostly has the quality and finish on its side."

Mr. Cant, of Colechester, has this year distanced all competitors. He writes to me, "that on the average he cuts many more Roses from the Briar than from the Manetti. He gets some splendid blooms from the latter, but not so constantly as from the Briar."

Mr. Charles Turner, of Slough, says, "the Briar for permanent trees, Manetti for first year from buds."

Mr. Cranston speaks decidedly for the Manetti, but I have been in the beautiful nursery at King's Acre, near Hereford, and the Briar does not thrive there. His Manetti Roses in a favourable season are magnificent.

Mr. John Keynes, of Salisbury, says, "the Briar for early, the Manetti for late Roses." He adds, "that he has just seen some blooms from the seedling Briar, grown by Mr. Prince, of Oxford, that utterly flabbergasted him." If they astonished a rosarian like John Keynes, who showed some years ago at Birmingham the finest forty-eight roses I ever saw, what must they be?

The Rev. E. N. Pochin, than whom we have not a more reliable rosist, amateur or professional, writes—"As a rule, I agree with you, and should vote for the Briar. If soil equally good, Briar of course. Practically Briar best, where it will grow."

It only remains for me to repeat the conviction of more than twenty-five years' experience, that, as a rule, the British indigenous Briar is a better stock for Roses than the Italian Manetti, but that in certain soils and certain seasons, the latter is most successful. I advise all young rosarians to give both a trial, not of one summer only, but of two or three, and to decide by results. S. REYNOLDS HOLE.

I HAVE accepted Mr. Hole's challenge, and written to the gentlemen to whom he refers, and I am glad to say that there is at least an equal number who say that the Manetti produces equally good, if not better Roses, than the Briar.

Mr. Cant (who, by the way, wrote unsolicited to me to say that he considered my stands at the Crystal Palace to be the best he ever saw staged by an amateur), says that in his soil the Briar does best, and that he cuts, for the most part, his prize blooms from that stock, but there are times when the Manetti is the best, and he would be very sorry to be without either. Mr. Pochin, who has written me a most interesting letter, too long to quote, considers that, generally speaking, Mr. Hole's statement that the superiority of maiden Briar blooms is correct, but of course (he adds) it is not a fair question, as all depends upon the soil, but if the conditions are the same in twelve different soils, the Briar will have the advantage in some places, and the Manetti in others.

Mr. George Paul says, the maiden blooms of Manetti are larger than those of the Briar, but the average quality of Briar blooms is, when they are well done, finer.

And now, Sir, for the other side.

Mr. Keynes, of Salisbury, says, the maiden bloom on the Manetti is equal, and in many cases superior, to that of the Briar.

Mr. Cranston writes me word to this effect:—"I have always maintained, and ever shall, that the finest blooms are to be obtained from Manetti, with, however, a few exceptions. Some sorts will not bloom well from maiden plants, these are best on the Briar and better still from one year cut back plants, on the Briar." Mr. Baker, of Heavitree (who in my opinion is second to none as a judge and cultivator of the Rose, who has supported my opinion in your last issue), is all for the Manetti. So that there are three who say decidedly the Manetti is as good, if not better, than the Briar; so Mr. Hole need not in his next edition say unreservedly the maiden blooms of the Briar are superior to those of the Manetti.

I may add that Mr. W. H. Radclyffe is decidedly of the opinion that the Manetti is superior to the Briar as a stock.

Monkton Wyld, Charnmouth. JOHN B. M. CLAMM.

Advices from Bordeaux state that the vintage, which seems to be considered of average quality, has been more abundant than at any time during the past ten or eleven years. But it has yet to face the weather until October.

NOTES OF THE WEEK.

— ROUNDHAY PARK, Leeds, is to be opened by Prince Arthur on the 19th of September.

— THE sub-tropical garden in Battersea Park is now in full beauty, and will, we hope, remain so for at least another month. We however advise all who wish to see it to do so as soon as convenient. It was never better worthy of a visit than at present.

— WE learn from Mr. F. Lane that the Midresfield Court Grape, as grown at Latimers, the seat of Lord Chesham, proves itself in every way a noble fruit, the bunches being perfect both as regards size, colour, and bloom, and the flavour unsurpassed. This is quite our own opinion of this grape.

— A CURIOUS fact with reference to Tomatoes has been pointed out to us by Mr. Spinks, foreman in the Royal Horticultural Society's Garden at Chiswick. It is that those planted near some diseased Potatoes seem touched with the disease, while others, in a part of the grounds where there are no Potatoes, are quite free from it.

— AN Aldon Fruit Factory has been established at Fowler, Adams County, Ill. The building is described by *The Western Agriculturist* as 36 feet by 74 feet, four stories besides the basement, three evaporators, and a capacity for drying 400 to 500 bushels of fruit or vegetables per day. This will give some idea of the scale on which fruit is dried in America.

— LOVERS of Gladioli should now pay Messrs. Kelway's grounds at Langport, Somerset, a visit. Their general collection of these showy flowers is in full bloom, and they have also in addition numerous seedlings in blossom, an inspection of which must necessarily be interesting. Their grounds may be seen any time between the 1st and 20th of next month, Sundays excepted.

— MR. C. M. PALMER, the founder of the prosperity of Jarrow, has announced his intention to provide a public park and recreation ground for that growing town so closely connected with his commercial career. This is good news for the mining population of Jarrow, who during their work hours are so surrounded and encompassed with smoke and soot that a green field must be a perfect paradise to them.

— SAXIFRAGA PELTATA, a distinct and rare Saxifrage, is now in flower at the Halo Farm Nurseries, Tottenham. It belongs to the Crassifolia, or large-leaved section. The flowers are rose-coloured, and judging from present appearances the plant does not present any very noticeable feature, but it is said that when well established it has an unusually large leaf-development for a Saxifrage, the foliage often measuring two feet or more in diameter, and if such is the case it may form an attractive foliage plant.

— IN many parts of the London parks now (26th August) there is a worse than wintry aspect, from the number of lime trees that are shedding their leaves. In many parts the ground is littered with the leaves. These in dying do not assume their natural autumnal colour, but become of a peculiarly disagreeable foxy hue. Some of the trees are bare, and the bare trees are much more agreeable to the eye than those on which the diseased-looking foliage still rustles. The Aesculus, Alantus, and Plane are still quite fresh and beautiful.

— THE temporary embankment of the Thames facing Battersea Park, a deep slope with a rounded bank above, is in an unprotected and very dangerous state. Yesterday week two infants and a perambulator rolled down it into the river, but were saved by a good and bold swimmer who happened to be near. We trust the Office of Works will protect this long embankment at once; its dangerous state must be evident to everyone who lauds at the Battersea Park pier.

— WE have seldom enjoyed so pleasing an effect in a garden as may now be seen near Hyde Park Corner. Through some beds of hardy Azaleas and Rhododendrons, edged with Irish Ivy, are now peeping the blooms of *Lilium speciosum*. This happy result has been brought about by inserting a few blooms of this beautifully coloured and perfectly hardy Lily here and there in the beds, and the autumnal beauty of the beds is as perfect in its way as that of the early summer, when the American plants blossom. Such touches as this show the true gardener.

— THE finest hardy shrub with ornamental foliage at present in full beauty of leaf, is the Golden Elder, i.e., a variety of the common Elder, with leaves suffused with golden yellow. It is one of the most valuable gains that has ever been made to our shrubberies, and not second in importance to the popular variegated Aesculus. Unlike that plant it will succeed anywhere, and it retains its colours through all weathers. In a dwarf state it may be used in the flower garden. Beds of it may now be seen at Messrs. Henderson's, Wellington Nurseries, St. John's Wood.

— MUSHROOMS are said to be more abundant this season within the area of the Malverns, than they have been known for years.

— AN expedition to fix the exact locality of the Garden of Eden is spoken of in America.

— THE culture on a large scale of sugar beet is about to be commenced in the county of Cork by thoroughly experienced continental growers. We have great confidence that it will prove successful.

— MR. J. TALBOT CLIFTON, lord of the manor of Lytham, in Lancashire, has presented a beautiful park of several acres in extent to the inhabitants of that parish. The park is situated at the north end of the town, and is very convenient for both residents and visitors.

— IN a recent number we gave some account of the flower beds in the neighbourhood of the Palm-house at Kew. We would now direct attention to a long bed in front of Museum No. 2, which in our opinion is the most attractive bed in these gardens. This is planted on the mixed system, *i.e.*, foliage plants are mixed with flowering ones, and the effect is excellent.

— ONE of our native parasites, the *Cuscuta Epithymum* or lesser Dodder, is growing on a plant of *Clinanthus puniceus*, in the No. 4 house, or what is generally known as the conservatory, at Kew. Its white thread-like dependent stems look like a bunch of thread fastened to the plant, giving the latter an appearance something like that of the bearded trees of Texas.

— THE finest crop of Tomatoes we have seen in the open air is in Mr. Bagley's market garden at Turnham Green. They are grown in rows in the open field, tied to stakes, and closely pinched in to one stem, all the late-set young fruit and nearly all the side shoots and leaves being pinched off. We did not think this crop could be grown so well in a field, about London, particularly in such a season as this.

— THE various kinds of *Colchicum* are now just coming above the ground about London, where we are glad to see they are receiving more attention than they did a few years ago. Many of our readers fond of hardy bulbs would be interested to see these. There are good collections in the London district at Messrs. E. G. Henderson's, Wellington Road, St. John's Wood; at Messrs. Osborn's, of Fulham; at Mr. Wray's, at Tottenham; and at Mr. Parker's and Mr. Peter Barr's, of Tooting.

— SUMMER flowering *Chrysanthemums*, a dozen varieties or so of which have been in flower at Chiswick for some time, are worthy of more attention than they get with us. It is very likely that we shall some day see as brilliant hues among these as among the late-flowering kinds. And few accessions to our flower gardens would be more valuable than a race of *Chrysanthemums* which would flower well in the open air before the severe frosts and cold rains of late autumn set in.

— THE first prize of £20 for the best plan for laying out the Highfield estate as a public park for Ashton-under-Lyne and neighbourhood has been awarded to Mr. Alfred Underley, and the second prize, £10, has been adjudged to Mr. G. Gill, Stalybridge. Great preparations are being made to secure the success of a show about to be held on the grounds. There is every prospect of an early laying out of the ground. The sum already collected amounts to about £7,000, and no doubt is entertained as to the promoters obtaining the additional £3,000 necessary.

— AS there is some probability that the Central Railway Company, which some time ago obtained powers to construct a new street from Tottenham Court Road, through Leicester Square, to Charing Cross, may not carry out their powers, the Metropolitan Board of Works are contemplating some improvement in the square. A resolution has been passed that it be referred to the engineer and solicitor to report when the powers of the company will cease, and what steps they have taken towards carrying out the scheme, in order that the Board shall, if they think proper, carry out the improvement independently of the railway company.

— LANDSCAPE gardeners who may be engaged in planting boulevards in London, or in improving our streets and squares, would do well to eschew the common Horse Chestnut. In Paris this year, where the season has been as moist as in London, the leaves are scar and withered, and many of the trees are quite leafless, while *Ailantus glandulosa*, *Acer Negundo*, common *Acacia*, *Ehretia*, and *Catalpa-syringifolia* at this date are full of vigour, and the foliage as green as could be desired. These are all used in the boulevards. The scarlet Chestnut in groups in the Parc Monceau, and when planted singly in streets, &c., does much better than the common kind, and is much planted as a boulevard tree. *Thuja aurea*, *Cupressus Lawsoniana*, and *Cupressus macrocarpa* grow well about Paris, and some of them have attained a large size.

RIVERS'S NEW NECTARINES.

THERE is now in fine fruiting condition, in the Sawbridgeworth Nurseries, a new strain of seedling Nectarines of remarkable distinctness and of the finest quality and flavour. Some of these varieties have been named, others are not so as yet, and most of them have the blood and fine flavour of the Stanwick. They have all been raised by Mr. Thomas Rivers, and are likely to cause his name to be gratefully remembered by all lovers of gardens, even if he had done nought else to merit such distinction. We strongly advise all interested in high class fruit culture to see these Nectarines.

THE EMBELLISHMENT OF RAILWAY STATIONS.

NOR long since you published a paper on the decoration of railway stations. I read it with interest, and quite agree with the writer that much more might be done in this direction than we are accustomed to see. Let me tell you what I saw a few days ago at Yalding Station, on the Maidstone branch of the South-Eastern Railway. On the south side of the line is the up station, and between the booking office and a signal box there is a small but very charming flower garden, laid out by one of the porters, who has a great fondness for flowers, and carefully tended by him day by day. The space occupied by this garden is some twenty-four feet in length by ten in width; it is open to the line on the west side; on the east side is a boarded fence, about five feet in height. About two-thirds of the way up this fence there is a broad shelf, which held ten rows of plants in pots, and those comprised *Pelargoniums* of all kinds, *Fuchsias*, *Stocks*, very nicely done, and many other things evidencing circular skill of no common order. On the ground level are two circular beds edged with *Armeria alpina*; in the centre of one was a standard Hybrid Perpetual Rose, (General Jacquemont); on the other a similar plant of the tea-scented *Gloire de Dijon*; with various plants in flower filling up the beds. On the east and south sides there is a narrow border edged in the same way, and occupied by *Paucias*, *Potantius*, *Geraniums*, &c. A low railing divides the pretty and well-kept garden from the platform. On the north side, at the end of the booking-office, is a small frame, not heated in any way, but occupying a snug corner, and here our horticultural friend winters his choicest plants. There are also two slips of border, one on each side of the line, close to the station. These were occupied by mixed plants, and the variety of colours presented by the several flowers was very attractive. Several of the Kentish railway stations are gay at this season of the year with flowers, but the station at Yalding stands out from all the rest that I saw in the course of a short run through a portion of the country, and I think its appearance deserves some notice in your columns.

R. D.

AN ABERDEEN FRUIT AND MARKET GARDEN.

THE following description of a garden of this kind, taken from the *Aberdeen Free Press*, may not be without interest:—The Gartthoe property, which belongs to Messrs. Moir & Son, of Virginia Street, Aberdeen, lies on the north bank of the river Dee, immediately above the old bridge. The extent of land is 24 acres, 130 acres of which have been converted into garden ground for the growth of fruit and vegetables. Commencing at the Bridge of Dee village, a good road, extending about a mile and a quarter, leads westward along the middle of the Gartthoe property, and past a handsome structure in the Elizabethan style—Gartthoe house—the residence of the proprietor, J. Moir Clark. The tasteful and extensive lawns, here stretching to the south and west, and the fine orchard, may be referred to as an excellent specimen of successful landscape gardening. Between the road and the river lies the principal part of the ground, devoted to the production of fruit, &c. It is bounded on the north by a high stone and lime wall, and on the south by the river, the average width of the gardens being perhaps about a furlong. The exposure of the ground is exceedingly good, and the contour varied by height and hollow in a remarkable degree, giving to the surface not a little of the picturesque in character. To gain a just idea of the great amount of labour that has been expended on the laying out of the gardens, it must be kept in view that various of these knolls, now nicely planted with fruit trees and shrubs, or growing heavy crops of vegetables, were formerly hard protuberances, producing nothing but whins, if even those; and that the embankment which runs along the lower margin for a considerable distance, to prevent the encroachment of the river when in flood, is also a new formation, from material taken down from the higher ground. This embankment is about seven feet in height, and perhaps twice as broad at the base, and covered on the surface with

a thick sere of grass. Alongside it we find a very large space taken up with Raspberry canes, staked in the usual manner. Some twelve acres in all are devoted to the growth of this fruit. About twenty acres are in Gooseberries, and thirty-five acres in Black and Red Currants. The breadth in Strawberries is thirty-five acres; but these are in three large divisions outside the wall, the south face of which, we may state, is occupied by young trees of the Morello Cherry, trained to it. There have been planted, in addition, at suitable distances, among the fruit bushes, two thousand Kent Cherry trees; two thousand Green-gage Plum trees; and six thousand Apple trees—all standards, of course. The space not filled by fruit bushes is filled up with vegetables. The extent of ground occupied in this way will be indicated, if we state that the number of Cabbages put in this season is 250,000; that the Carrot crop is estimated at 150 tons; Peas at 2,000 pecks; while 20 tons of Rhabarb for bottling have been grown for the season. In addition to this, Turnips, Potatoes, Beetroot, Parsnips, &c., are grown in considerable quantity in plots in the open spaces between the rows of fruit bushes.

The crop of fruit alone, in the Garthdee Gardens, is estimated at 50 tons for this season. The gardens having been laid out only three years ago, the Goosecherry and Currant bushes have not yet attained to anything like their full productive power, while only a very few of the fruit trees have begun to come into bearing. A year or two hence, the produce of the gardens will naturally be very largely increased; meanwhile, under efficient management, both the fruit and vegetable departments seem to be in a thoroughly thriving condition.

In all matters of detail, the laying out appears to have been very carefully gone about. At intervals of sixty yards, Beech hedges have been planted to afford the requisite shelter to the fruit trees and bushes; and the means of irrigation in a time of drought are at hand, in the shape of a water-main, that runs along under the broad walk which intersects the gardens from end to end. Fire plugs are inserted at suitable distances, and water from the main can be distributed to the boundary of the gardens, either way, by means of hose-pipes. The water in this main is, we may say, obtained, by meter, from the Cairnton Gravitation Works, which supply Aberdeen. During the present season, when moisture has been abundant in the form of rain, there has been little or no occasion to resort to artificial means; but in a comparatively dry season, such as last summer, large quantities of water are used. Near the centre of the gardens is a tool-house, and under the same roof, separate accommodation for the male and female workers taking their meals. Of these, the number employed as hoers, and in picking fruit, &c., at the present season is 150. Even in winter, the number of men required to do the needful digging, and so on, is from 30 to 40.

TREES OF LIBERTY.

THE British May-pole was transported to America, and during the war of independence was adopted by the Bostonians as the emblem of liberty. When La Fayette returned to France he had one of these symbolic trees, planted on a broken crown and sceptre, worked into his saddle-cloth, and shortly afterwards the emblem spread through France. The first person to plant one of these trees appears to have been M. Norbert Pressac de la Chassaganie, curé of Saint-Gaudens, near Civray, in the department of the Vienne. The tree selected was a young oak, which was planted in the centre of the village in presence of the municipal council and the inhabitants in general. The curé made a touching speech in favour of the revolution; and after the ceremony all the persons engaged in lawsuits referred their disputes to arbitrators, rich and poor embraced each other, and there was universal rejoicing. This episode (adds M. Louis Combes) was repeated through thousands of communes, and these trees became as sacred for the citizen as the standard for the soldier. In May 1792, there appear to have been 60,000 of these trees in France, and a number had already been planted in Paris. The Marquis de Villette, who had warmly adopted the new ideas, wrote at that period:—"One may see in Paris 200 trees of liberty covered with garlands, ribbons, and flowers." One of these trees was planted in the gardens of the Tuileries, Louis XVI. presiding at the ceremony. It is needless to say that it was afterwards torn up, because it had been "sullied by the impure hand of Capet." The Convention authorised the "orphans of the country" to destroy it, and to set up another tree in its stead. The *Peuplier* on account of its name (*Populus* or Poplar), was the tree generally preferred. The ceremony of planting these symbols gave rise to revolutionary orgies, during which people danced and sang the "Ça ira" and the "Carmagnole," magistrates, generals, representatives of the people, and constitutional bishops and curés, no doubt headed by Goose Gobel, joined in the revels and footed it round the tree. "At the planting

of a tree of Fraternity in the Carrousel," says M. Louis Combes, "the maire of Paris with all the municipal councillors, wearing their scarfs, danced a patriotic farandole pell-mell with the federals, savoyards, and sans-culottes of all professions. The author excuses these saturnalia, in which he relates that men who afterwards became very sedate and imposing personages joined. "Why not?" he asks. "Did not David dance before the Ark? Up to the year VII. no one was shocked at this show of enthusiasm, and the general could dance with his soldiers round a tree of liberty set up in camp without compromising his dignity." In the height of the Revolution every village was obliged to have its tree, round which a *fête* was held on the 21st of January—"the anniversary of the just punishment of the last King of France." From divers official letters it would seem that these trees were protected by the authorities so late as the year X., when Napoleon was First Consul. The cutting down of them was punished with death. At Rouen nine people were executed for this crime. At Amiens a tree was sawn in two, and a few days later a new tree was planted with great pomp, the trunk of the old tree figuring in the procession, escorted by a thousand men with arms reversed, and marching to the sound of funereal music. To show how completely these symbolic Poplars and Oaks passed into the customs of the people, M. Louis Combes writes as follows:—"During the counter-revolutionary movements which took place in some communes near Coulommiers, a locality was suddenly invaded by bands of peasants, who, after having crushed the patriots and committed several excesses, wished to celebrate their triumph by singing a 'Te Deum!' The idea of singing a 'Te Deum' in Frimaire of the year II., when the worship of Reason had been established in all parts, and when priests had abjured by thousands! This sole fact classed these men on a level with the Vendéans, and in the lowest regions of the counter-revolution. Well! these counter-revolutionists, these rebels, these blind enemies of the Republic and of philosophy, never dreamed for a minute of opening the church to celebrate their victory over the Republicans, they went spontaneously and chanted their 'Te Deum' at the foot of the tree of liberty!" Towards the close of his volume M. Louis Combes has naturally to tell how the reaction fell upon these trees and rooted them out of the land. Of the trees which were planted in 1818 the author has but a poor opinion; he talks of them of having been "first of all watered by the reaction," and of having received the benedictions of the clergy—benedictions which, he scoffingly adds, did not save them from the axe of M. Léon Faucher in 1849.

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM AUGUST 22ND TO AUGUST 29TH, INCLUSIVE.)

BY OUR OWN REPORTERS.

Abronia umbellata	Colechicum autumnale	Gentiana Andrewsii	Sedum albicans
Anoda hastata	byzantinum	Helenium atropurpureum	albo-rosea
triangularis	speciosum	Linaria italica	spicatum
Apios tuberosa	variegatum	Nuttallia italica	pectabile
Arnica Chamissonii	Colutea orientalis	Coreopsis coronata	Semprevivum
Aster lamarifolius	Coreopsis coronata	Coronilla jucea	Heuffellii
Novae Angliae	Novi Belgii	Shortii simplex	Solidago elliptica
Astragalus leontinus	Campanula isophylla alba	Centaurea americana	neglecta
Chrysoeema linozyris	Clethra acuminata	Gladolus formosissimus	nemorosa
		Colchicum autumnale	ulmifolia
		Helenium atropurpureum	Spraguea umbellata
		Linaria italica	Stachis Portunei
		Nuttallia italica	Teucrium orientale
		Coreopsis coronata	Verbena pulcherrima
		Coronilla jucea	Ximenesia encelioides
		Novi Belgii	Zinnia Hageana

THE INDOOR GARDEN.

CYCADS.

MANY valuable additions of late have been made to this class of plants; prominent among them are *Encephalartos villosus* and *E. Ghellinckii* (or *gracilis*), from Natal; *Macrozamia Dennisonii* and *M. Frazerii*, from Anstralia. But the most interesting, and perhaps the most beautiful, is *Bowenia spectabilis*, from North Queensland. This is a stemless plant, and does not confine itself to one point of development, but forms several crowns, from which it throws up single fronds that develop like an umbrella, or similar to the curious *Amorphophallus* and *Godwinia*; the leaflets are rhomboid; it is fond of heat and moisture, and might be used by way of change as a plant for table decoration. The best Cycads adapted for general decoration are the tall-growing, such as that represented in the accompanying woodcut. This kind (*Cycas circinalis*), is a native of the East Indies, and is one of the finest of the genus, attaining a height of from ten to twelve feet, and furnished

Cycas circinalis.

with a noble head of fronds, of a dark shining green above and of a paler colour beneath. As a dwarf plant for pedestals or vases, *C. revoluta* is good. It will stand more cold than any other Cycad. *C. Rumphii* is another East Indian species allied to, if not the same as *C. circinalis*.

Among *Ceratozamas*, *C. mexicana* is a fine plant, when it can be set on a tall pedestal, where its fronds, which grow from six to eight feet in length, can hang down gracefully. *C. Miqueliana* is more erect than the last, and is also a fine Cycad. A plant has made its appearance lately under the name of *C. Kusteriana*, but it is very like, if not the same as, *C. Miqueliana*. The *Ceratozamas* are all Mexican.

Zamias proper are West Indian and Tropical American plants; they are dwarf in habit, and do not form much stem; the only species worth cultivation as an ornamental plant is

Z. Skinneri, which I consider to be the grandest of all Cycads. *Encephalartos* is an African genus which contains some of the noblest of plants. *E. Caffra* (the Caffer's Bread) is a giant which grows from ten to sixteen feet in height, and spreads from twelve to fourteen feet in width; its foliage is dark green, spineless, very dense and stiff; a very distinct plant. *E. Altensteinii* is of a deep green, more erect than the last, and has a few spines on the margins, and one at the point of the leaflets. *E. lanuginosus* is similar to it, but has more wool at the base of the leaflets, and is spineless; both very fine plants. *E. villosus* has many spines on the pinnæ, is more erect in habit, and very woolly at the base of the fronds; a noble decorative plant for warm conservatories. *E. Lehmannii* is a smaller plant, with spineless glaucous fronds; useful for variety, and in small houses. *E. horridus* is a moderately vigorous grower, the fronds of which are glaucous; but, being very spiny, it is unsuitable for general purposes. *E. Ghellinckii* or *gracilis*, a recent introduction of Mr. Bull's, is an erect grower, with narrow villose leaflets, almost snow white; it is a moderate grower, and is an extremely elegant plant. *E. cycadæfolius* resembles this species, but its leaves are broader, and not quite so white. *Dion edule*, a native of Mexico, is an erect growing plant, very symmetrical, glaucous, and slightly woolly; it grows moderately large, and ranks among those plants of the first class. Of the Australian *Macrozamia*, *M. Dennisonii* (*Catakidazamia Hopii*) is the best. It is a strong grower, with spreading, bronze-green fronds; this is a plant which will stand greenhouse treatment. *M. Frazerii* is an elegant, bright green foliated plant, the fronds of which are from two to three feet long, and recurved; the stem is very thick, oftentimes, indeed, as thick as the plant is high. Young plants of it are found to be very useful for vases. *Stangeria paradoxa*, a native of South Africa, must be regarded only as a curiosity. It is closely related to *Encephalartos* in structural characters, but differs remarkably in habit and foliage. It has a stout fleshy stem or trunk, which seems to possess but little power of growth. These are a few of the best for general decorative purposes; but for those who only want two or three for conservatory ornamentation, I would recommend *Encephalartos villosus*, or *Altensteinii*, *Cycas circinalis*, and *Macrozamia Frazerii*. For stove decoration *Cycas circinalis*, *Dion edule*, and *Ceratozamia Miqueliana*, stand in the first rank.

The best soil for them is a mixture of good loam and sand, and they should be potted firmly; when pot-bound a little manure-water will be of benefit to them. If a plant gets out of health it should be cleared of its soil, all dead roots should be cut off, and it should be put into a small pot in poor soil, set on a good bottom heat, and kept moderately dry. When Cycads are developing their fronds they should not be moved, if that can be avoided, as in moving them the young fronds often receive a twist from which they seldom recover. When in full growth they should be watered freely, but when at rest it is best to keep them moderately dry. When a seaweed-like growth forms just under and on the top of the soil in which these plants grow, it is a sure sign of health, and should not be disturbed; when this is absent it is a sign that the plant is not vigorous at the roots, and that care is required in watering it. Cycads, like Palms and Tree Ferns, belong to the aristocracy of the vegetable kingdom, and deserve more attention than they generally get from cultivators. J. CROUCHER.

TRICHINIUM MANGLESII.

BY W. THOMPSON, IPSWICH.

As the introducer of this pretty Amaranth, perhaps you will allow me to reply to your correspondent "W.'s" enquiry respecting its management. As far as my experience goes, the secret of successful treatment consists in keeping up a succession of young plants. After once or twice flowering, it is rare to see a plant maintain a presentable appearance. The foliage produced the second season is always narrower and weaker than that on plants which have not yet bloomed, and the removal of the dead flower-stems, which all spring from the crown, often gives the plant a scraggy look. I know not what may have been effected by more skilful cultivators, but in my hands the only satisfactory mode of propagation

was found to be by root-cuttings. If a plant two years old is examined, it will generally be found to be furnished with a somewhat fleshy root of the size of an ordinary tobacco-pipe, or thereabouts. This should be cut into short pieces, say from three-quarters to one inch in length, and the fragments should be treated precisely like seeds, sowing them in a soil composed of finely-sifted peat and sand. A stock of young plants may be thus obtained with certainty, but the patience of the amateur may be put to the test, for several weeks will probably elapse before the root-cuttings develop their latent buds. Sooner or later, however, growth will take place; of course the strongest cuttings will furnish the most vigorous plants. Cuttings of the flower-stems can be rooted, but they never make satisfactory plants. Sandy peat, with a little loam, is apparently the best compost for this plant; and the greenhouse is undoubtedly its proper place. I never found it do so well in the open border.

LUCULIA GRATISSIMA.

To Mr. Hobday's excellent instructions (see p. 656 of your last volume) respecting the culture of this most beautiful and deliciously fragrant shrub, I beg to add my experience in reference to its growth as a pot plant. The chief difficulty is to strike it from cuttings; but that, after a little practice, may be overcome. I select cuttings of short-jointed wood as early in the season as they can be had in a rather hard state. These may be obtained in May, if a plant is left without being cut down after flowering. I slip them off with a heel, and use the knife merely to remove any loose bark which may extend beyond the wood, and to divest them of superfluous leaves. Thus prepared I insert the cuttings in small thumb-pots filled with sandy peat, and give a moderate watering, to settle the soil. The latter should be in a rather moist state when used, as I find cuttings of the *Luculia* are impatient of damp, which, in the event of repeated waterings being necessary, it is difficult to prevent. After potting, I place them in a shady situation in a house, the temperature of which may average 55°, and cover them with a hand-glass. The only further attention which they will require will be an occasional sprinkling of water; this should be applied towards the evening, and the plants should be left uncovered until the following morning. If cuttings are properly attended to in these respects, and allowed to remain undisturbed during the summer, the probability is that nine-tenths of them will root. As soon as they are fairly rooted, they will grow away freely, and should be shifted into a size larger pots, and gradually exposed to a freer circulation of air. No advantage will be gained by keeping them in a temperature exceeding 60°, as, if they are kept in a warmer place, they will grow weaker, and will require a great deal of stopping to keep them bushy. As the sun becomes powerful, it will be necessary to shade at least for a few hours during the middle of the day, for this plant is exceedingly liable to suffer from direct sunshine; and I have never been able to do any good with it, except when I could protect in this respect; I have also found that sudden exposure to drying currents of air injures it more than most plants. With attention to its wants in these respects, and if allowed plenty of pot room, and kept free from insects, nice specimens may be formed by the end of the first season, each of which may produce flowers, but this will greatly depend upon their having been stopped at the proper season. Weak plants should not be stopped at all, and there will be nothing gained by stopping even the stronger plants more than once, and none should be stopped later than the middle of July, or the first week in August. As soon as they have pretty well ripened the wood from which flowers are expected, they should be kept rather cool, or they may be removed to a shady but airy situation in the greenhouse, or to any place where they can be assisted to harden their wood by a cool, dry atmosphere. Such of the plants as have never been stopped will probably show flower towards the middle or end of September, when they may be removed to a damper atmosphere and kept rather moist, so as to encourage them to develop their beauty and fragrance; and if the plants are removed from the greenhouse or cool position in which they have been placed to ripen their wood, to a warmer situation, at intervals of about a fortnight, they will afford a succession of flower from September to March.

When the plants have done flowering, they should be rather sparingly supplied with water for a fortnight previous to their being cut back, and they may be stowed away in any spare corner of the greenhouse or cold pit, where they will be safe from their great enemy—damp. After being treated somewhat dry for a fortnight, they should be cut back sufficiently to secure a compact, bushy growth, and that is the time when they can, with least trouble, be

thoroughly cleared of insects. To the attacks of thrips they are especially liable, as most delicate plants are, and if these are permitted to establish themselves they will do much injury during the ensuing season. After the plants have been cut back and cleaned, a portion may be encouraged to grow early in the season, so as to come into flower in the autumn; but it will be advisable to introduce them into heat very gradually, otherwise they will break their uppermost buds only, and will consequently become naked below. If the plants can be kept during their second season's growth in a moist growing atmosphere, where they will receive abundance of light and protection from the direct rays of the sun during the summer months, and also be guarded against the attacks of insects, and allowed plenty of pot room, they will form handsome specimens, and flower abundantly during the dull months of winter.

As regards soil, the *Luculia* is not particular. For its culture in pots, I use about one-half turfy peat, and one-half light turfy loam, adding a portion of silver sand, more or less, according to the nature of the other materials. Those who have room for the *Luculia* in the conservatory border will find it a most eligible plant for such a situation. But it succeeds best shaded from the direct rays of the sun from the beginning of May to the end of August; and in order to bloom it in perfection, it also requires to have the house kept rather close. It will not thrive in a temperature under 40° or 45°; for where the temperature does not average this the flowers are liable to damp off. Planted out, it will succeed perfectly in any light soil, whether peat or loam. It will be found to require some attention, in order to keep it clear of insects, and also the same treatment, with regard to stopping and cutting back, as recommended for young plants; but as when planted out it cannot receive that assistance in the way of heat and moisture, which can be given to plants in pots, never stop later than the middle of July. S.

Lapageria alba.—It is unnecessary to say that this is one of the most beautiful of greenhouse climbers; yet it too often bears the character, but unjustly, of being a slow and uncertain grower. It is not so, however, for it grows and blooms as freely as the well-known *L. rosea*, and requires precisely the same kind of treatment. Both kinds have also the advantage of coming into bloom in the autumn, when most other climbers have done flowering. In the Royal Exotic Nurseries, Chelsea, planted along both sides of the central passage of the entrance conservatory, may now be seen both kinds coming profusely into bloom. *L. rosea* has been planted four years, and *L. alba* two; both have grown rapidly and under exactly the same circumstances, yet the white promises to outstrip the red in point of growth, and to produce flowers quite as freely. The leaves of the white kind are more cordate in shape than those of the red, and they do not taper so gradually towards the apex, a circumstance that may help purchasers to distinguish the one from the other when both are out of bloom.—F.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Plumbago capensis.—One of the best conservatory climbers in flower at the present time is this *Plumbago*. In the conservatory of the Royal Botanic Society, Regent's Park, two fine planted-out specimens of it are producing a perfect mass of light blue flowers. It should be used against pillars, &c., in every conservatory and large cool house.

Mesospidium vulcanicum.—This is one of the prettiest of all cool-house Orchids; it is dwarf in character, and produces nice spikes of crimson flowers. It is, moreover, quite a new plant, having only flowered this season about London for the first time. As a companion to *Odontoglossums*, *Cypripediums*, and *Masdevallias*, it will form a valuable acquisition. It is now in good bloom at the Exotic Nurseries, Chelsea.

Moss as an Evaporating Surface.—Many are the methods employed for maintaining the atmosphere of Orchid and other plant-houses in a healthy, moist condition. Some place finely-sifted gravel on the stage shelves, in order to retain the moisture; but a better way is to place a layer of sphagnum on the shelves, and on other evaporating surfaces. The sphagnum will be found to retain more moisture than any other material that is used. This is the plan now adopted in all the leading London nurseries.

Eucharis amazonica.—I have grown this plant for four or five years, but have not been able to flower it. Can you or any of your readers help me?—AMATEUR. [Mr. Hovard, of Balham, replies as follows: the *Eucharis amazonica* should be placed in a stove or warm frame, well exposed to the light. An ordinary warm dung frame will do. Let the temperature be from eighty-five to ninety-five degrees, giving little air, and syringe the plant well early in the morning, and at 2 p.m., when the air should be taken off, no matter how hot the sun is. Under such conditions the plant will throw up flower spikes in ten days if in a healthy state].

Cephalotus follicularis.—This interesting little pitcher plant is now in as fine condition as we ever remember to have seen it, in the gardens of S. Rucker, Esq., Wandsworth; some of the best of the pitchers are nearly as large as an ordinary-sized small tea-cup. They are nicely tinged with brown, by being a little exposed to the sun, yet it is not advisable to expose them too much, as they are apt to get scorched. This pitcher plant is grown here in spongy material in small pots, that are inserted in others two sizes larger packed with sphagnum, these again are inserted in others still larger, prepared with sphagnum in the same way, so that the plants, though really in large sixty-sized pots, appear to be in pots much larger. They have no bell-glass over them, and are kept in an intermediate house, where they receive a good supply of water.

THE FRUIT GARDEN.

EFFECTS OF SPRING FROSTS ON PEAR BLOSSOMS.

BY RICHARD VARDEN.

THE following is the result of an examination of several thousand Pear blossoms, made some years ago to satisfy myself of the extent of injury they sustained from frost, under various circumstances of position. The mode of proceeding was, to examine in each case a given number of blossoms, generally one hundred. All that showed discoloration, when nipped through the lower part, were assumed to be injured, while those of a natural colour were considered good. Doubtful ones were thrown aside and not reckoned.

1. The first inquiry was, whether blossoms might be taken indiscriminately in all stages of development, or in average stages only. On examination, it was found that late blossoms were least injured. Thus, in one hundred of each,

	Bad opened blossoms.	Bad unopened.
Colmar d'Été had	100	42
Susette de Bayay	89	58
Easter Beurré	94	64

giving an average of ninety-eight bad blossoms out of the hundred of those fully opened, and but fifty-five out of the hundred of the unopened. This great difference showed, that for purposes of comparison, only such blossoms as were an average of forwardness, for the particular variety, should be taken.

2. The next comparison was, average blossoms taken from protected and unprotected situations of equal elevation, the protection being a hedge with elm trees, on the east or windward side of the plantation. Out of one hundred blossoms of each sort, the numbers of bad were as follow:—

	In the sheltered.	In the exposed situations.
Hessel	78	92
Louise Bonne, of Jersey	83	96
Williams' Bonchrétien	82	88
Glou Morceau	20	19
Average	67	72

showing that the shelter named had on this occasion lessened the injurious effect of the frost about twelve per cent.

3. The third point examined was, whether varieties whose blossoms are equally forward are equally hardy. The result proved they were not. Thus, in blossoms equally developed, the trees being free from shelter, and on ground of nearly the same level:—

Beurré Diel had	68 bad in 100.	Susette de Bayay	58 bad in 100
Fondante Van Mons	9	Easter Beurré	64
Doyenné d'Été	18	Williams' Bonchrétien	85
Colmar d'Été	42		

From these preliminary examinations, it appeared necessary, in investigating the relative amounts of injury done by frost at different heights, to compare only trees of the same variety, taking the average blossoms of each kind, and avoiding shelter. The result was as follows:—

	Height in Feet above Sea Level.	Number of Bad Blossoms in 100	Height in Feet above Sea Level	Number of Bad Blossoms in 100
Colmar d'Été	48	71	58	97
Doyenné d'Été	48	18	60	88
Marie Louise	56	19	100	82
Williams' Bonchrétien	50	88	59	82
Ditto on Quince	51	85	97	61
Louise Bonne of Jersey	48	92	51	92
Jargonelle	53	79	60	97

Average of the lower, sixty-five bad; of the higher, eighty-six bad.

These results are too conflicting to found any theory upon, but they show that elevated grounds are not always safest, as many fruit-growers suppose. Perhaps fogs and dews, the assumed cause of the inferiority of low situations, were absent on this occasion, or prevailed as much or more on the higher ground. This point, however, was not observed.

5. The fifth subject of comparison was, the relative amount of injury sustained by the blossoms of several well-known varieties, growing at nearly the same height above sea level, viz., from forty-eight feet to sixty feet, shelter being avoided, and the average blossoms of each kind selected as before. The result gave the following number of bad blossoms in the hundred:—

Fondante Van Mons	9 bad in 100	Duchesse d'Angoulême	74 bad in 100
Beurré de Capiaumont	18	Knight's Monarch	76
Doyenné d'Été, on Quince	18	Susette de Bayay	78
Marie Louise	19	Jargonelle	79
Glou Morceau	19	Easter Beurré	79
Summer Franc Réal	36	Hessel	85
Colmar d'Aremberg	42	Williams' Bonchrétien,	
Citron des Carmes	46	on Quince	85
Soldat Laboureur	46	Ditto, on Pear	88
Beurré Bretonneau	55	Triomphe de Jodoigne	88
Comte de Lamy	59	Doyenné d'Été, on Pear	88
Van Mons, Léon le Clerc	62	Napoléon	90
Brougham	64	Louise Bonne, of Jersey	92
Orphéline d'Enghien	66	Soldat d'Espéran	92
Beurré d'Amanlis	68	Vicar of Winkfield	92
Passé Colmar	70	Doyenné Gris	94
Colmar d'Aremberg	70	Beurré Diel	95
Colmar d'Été	71		

Discouraging as this was for many favourite kinds, I did not entirely despair of a crop. My trees were very small—only planted three or four years—so a few Pears on each would have been sufficient.

6. I found, sixthly, the number of blossoms on trees planted four years to average about—

600 for	Louise Bonne, of Jersey (Quince).
200 for	Williams' Bonchrétien (Pear).
500 for	Beurré Diel (Quince).
300 for	Beurré d'Amanlis (Quince).

which figures, after deducting the before-mentioned percentage of bad blossoms of each kind left:—

48 good blossoms for a	Louise Bonne, of Jersey.
30	Williams' Bonchrétien.
25	Beurré Diel.
96	Beurré d'Amanlis.

more than sufficient for a crop on such young trees, if all arrived at maturity.

7. The observations were extended to perry kinds, but not knowing the names (many being unknown seedlings), very little benefit could result, as the great difference of their hardness, even in similar localities, rendered averages or comparisons imperfect; for instance, it was found that the number of bad blossoms ranged as under—

A tree at 114 feet above sea level, all bad.

75	"	"	"
63	"	"	"
60	"	"	"
48	"	"	none bad.
47	"	"	"
45	"	"	"
36	"	"	"

with almost every intermediate degree of damage in the others. These blossoms were taken without reference to average state, just as they happened to be gathered, and none of the trees named were particularly sheltered.

8. On comparing the perry trees growing on the western or sheltered side of the hill, the average of twenty-two trees gave thirty-three damaged blossoms in the hundred; while on the eastern or exposed side of the hill, the average of thirty-three trees gave forty-one damaged in the same number—a difference of about twenty-five per cent. in favour of the sheltered aspect.

9. Little or no difference was perceived in amount of damage done to trees of 15 or 20 years old, and to trees of from 80 to 100 years; the average being 32 per cent. of damage to the former, and 31 to the latter. Quite young trees indicated a much larger amount of damage, but the point was not investigated, the necessary materials for a fair comparison not being at hand.

The foregoing examinations were made on the 31st of April, and the 1st and 2nd of May, 1855; after which, owing to the occurrence of more severe frosts, which entirely destroyed the blossoms of many choice varieties, they were discontinued. There was no fruit (except perry kinds) on any of the trees examined, except a few Williams' Bonchrétien. The May frosts completed the destruction of all the blossoms of table varieties.

The temperature of the nights, as registered at Worcester, eight miles distant, at a spot 100 feet above the sea, was as follows:—

	Minimum in Shade.	Radiating on Grass.	Minimum in Shade.	Radiating on Grass.
March 1	36	32½	March 29	30
" 5	30½	25½	" 30	25
" 6	28	24½	" 31	28½
" 7	31	28	" 2	22½
" 8	30½	26	April 3	32
" 9	29	27	" 5	31
" 10	29	28	" 13	35
" 12	27	24½	" 19	31½
" 14	32	30	" 20	35
" 20	31	28	" 21	32
" 22	32	31½	" 23	26½
" 23	32½	31½	" 24	29
" 24	31½	30	" 26	36
" 26	24½	21	" 27	30
" 27	26	21	" 30	32
" 28	31	28		

Many of the foregoing frosts were accompanied by strong winds

from the east and north-east, but not much wind from other quarters. The examination of the blossoms was made between this and the 3rd of May, after which the temperatures were as follows:—

	Minimum in Shade.	Radiating on Grass.		Minimum in Shade.	Radiating on Grass.
May 3	23	22½	May 12	36	32
" 4	33	31	" 17	35	29
" 5	25	20	" 18	30	27
" 9	23	22	" 23	37½	32

The above observations add little or nothing to the existing knowledge of frosts; but the results being given in figures, are in some respects more definite and convenient for comparison than description can be, and on this ground may prove interesting to fruit growers. Should the method of investigation adopted be considered sufficiently correct, the system might with advantage be extended to various localities, and the results, when collated, given as rules to assist fruit planters in the selection of sites and varieties for orchards, &c., and might perhaps lead to the discovery of laws regulating the action of frost at present hardly anticipated. Perhaps the first series of experiments might with advantage be confined to some one well known and widely diffused variety, such as the Jargonelle, which, if numerously reported on, might be made an index for comparing the earliness or lateness of localities, aspects, elevations, &c.; by the dates when the blossoms pass through the several stages of bud, flower, and setting; and also give, by noting the percentage of damaged blossoms, a more correct idea than we at present possess of the relative effects of frost under the various circumstances of latitude, elevation, aspect, &c. In after seasons, when other varieties are under examination, the results could, by comparison with a Jargonelle growing under similar circumstances, be reduced to a common standard by simple calculation.

In this neighbourhood many of the spring frosts were accompanied with fog, and proved far more destructive than those of 1855, although the temperature was not so low by several degrees—the minimum then being on the 5th of May 20°, whereas the minimum of the present blossoming season, which also happened to be the 5th of May, was only 26°. This appears to support the opinion that foggy or wet frosts are more destructive than dry ones.

The principal spring frosts were:—

	Minimum in Shade.	Radiating on Grass.		Minimum in Shade.	Radiating on Grass.
April 21	32	23	May 2	31	27
" 23	31½	27	" 3	32	30

The damage caused by the earlier of these frosts was greatest on the low grounds, where the fogs most prevailed. I cannot speak of the later ones, as almost every blossom was destroyed, and comparison rendered impossible. At 48 feet above the sea and 8 feet above the bottom of the valley, Beurré Diel had 95 blossoms out of the 100 destroyed, while at 112 feet above the sea, it had but 12 out of the 100 that were damaged. The injury to blossoms diminished progressively with their height from the ground, thus—

	Above the ground.....	10 feet	20 feet	30 feet
Standard perry Pear tree, near brook, 40 feet above sea level		95	90	60
Standard perry Pear tree, near last, 40 feet above sea level		50	40	20
Standard perry Pear tree, on higher ground, viz.: 48 feet.....		20	0	0

And the amount of damage was as great on the leeward as on the windward side of the trees. I regret there are no means of comparing these observations with each other, to ascertain the relative advantages of height of ground and of height above the surface—I mean of dwarf trees on elevated ground, compared with the upper parts of standard trees on lower ground, rising to the same level.

SUMMARY.

1. Blossoms in bud are less injured by frost than those in flower; hence as frosts decrease in severity as the season advances, late blossoming is one source of hardiness.
2. When frosts are accompanied with wind (*i. e.*, black frosts) the injury to blossoms is lessened by hedges, or screens, on the windward side of the trees.
3. Varieties differ in hardiness, though their blossoms be equal in forwardness.
4. Blossoms on low ground are occasionally as safe, or safer, from frosts than on high grounds; safer from black frosts, but more liable to white frosts.

5. Varieties may be arranged according to their power of resisting frosts, but not at present, from want of sufficient data.

6. The blossoms on free-flowering varieties are so numerous, that five per cent. would be sufficient for a crop, if they arrived at maturity.

7. Varieties differ so much in hardiness, that occasionally frosts, which destroy all the blossoms of one kind, leave all the blossoms of another uninjured.

8. When frosts are accompanied with wind (that is, black frost,) the injury to blossoms is greater on the windward than on the leeward side of a hill.

9. The blossoms of old trees, and growing trees, if not very young, are equally hardy.

10. White frosts accompanied by fog are more destructive than dry frosts, and the damage is greatest on the low grounds, or wherever the fogs are most dense.*

The injurious effect of frost on vegetation is increased by rapid thawing. In the severe frost of Christmas, 1860, a Privet hedge near the above mentioned Pear trees was killed where protected on the east side from the rising sun by Laurels, &c., but not injured in the parts exposed to its early rays. Dr. Lindley also mentions an Australian plant at Chiswick which had its blossoms killed by frost on the south side of the wall against which it was planted, but spared where it lapped over the wall on to the north side. A common sort of Camellia stands the winter in Somersetshire, planted at the foot of a north wall where the sun cannot reach it, but dies if the wall so incline to east or west as to receive winter sun. The injurious effects of rapid thawing induce many practical orchardists to prefer north and north-east slopes of hills for perry or cider trees where quantity and not quality of fruit is most considered.

BANANA CULTURE.

The Musa or Plantain is one of the best of our less known cultivated fruits. It is an undoubted acquisition to the dessert, and when the fruit is properly ripened it is delicious and highly relished by most people; even those who do not take to it at first very soon acquire a taste for it. Musa Cavendishii is the most eligible variety for general culture, as it is one of the dwarfest, and does not require a lofty structure to accommodate it. Neither does it require such a high temperature as some. It is a most prolific bearer, yielding in a chance way bunches of fruit weighing not less than fifteen pounds or twenty pounds, and under liberal treatment this is sometimes more than doubled. For the benefit of such as are not familiar with the plant, I may briefly describe it. Musa Cavendishii grows from six feet to ten feet high, the leaves themselves adding about a half to the height. Irrespective of its fruiting qualities, this Musa is a noble object, and forms a grand and imposing background to any collection of stove plants. When ripe the fruit is yellow, the skin peels easily off, and the soft, pithy-looking body within is the eatable part. The bunch ripens in succession, beginning at the base, and one bunch will afford a supply for a considerable time. The flavour is better and more piquant when the fruit is gathered before it is quite ripe. Indeed, it has been stated that, if the whole massive bunch is cut off just when the upper tier is getting ripe, and hung up in a dry, airy fruit room, the fruit will ripen slowly, and afford a supply for two months. This, however, is improbable; for when the first fruit begins to ripen, the greater portion is quite green and not fully swelled, and it requires a considerable degree of heat to ripen it. By pulling the pips or fruit off singly, however, when turning yellow, as I have stated, I have had fruit of it for a long time in succession.

As regards culture, a house should be wholly devoted to this Musa. Five or six bunches of fruit in the year will, as a rule, be found more than sufficient, perhaps, for a supply, even in a large establishment; however, in growing the plant for its fruit, something like a system must be followed. A roomy plant stove, either span-roofed or lean-to, will do; if the former, the plants must be grown along the centre of the bed in the middle of the house where there is most room for them

* There are two kinds of frost:—1st, black frost, caused by Polar currents, and scarcely ever occurring in a calm. 2nd, white frost. This is of local origin, being the effect of terrestrial radiation, added to a cold atmosphere, and white frosts occur only in calms, though the air is actually moving at a slow rate down the slopes (see "Book of the Farm," page 143). As a general rule, black frosts do not occur without wind, nor white with wind.

if the latter, they should be grown along the back. Although this *Musa* will grow, and even fruit, without bottom heat from pipes, provided the temperature of the house is kept well up, still it is much better to provide means for keeping the temperature of the soil to 80° or 85°. The bed may be like an ordinary Pine bed, and about three feet deep, which will allow a foot of drainage and two feet of soil. As this *Musa* is a rapid grower and a luxurious feeder, it requires a rich and open soil; loam and rough leaf-mould or well rotted hotbed manure in equal proportions will suit it well. The bed should be filled up to within a few inches of the top of the kerb stone, so as to allow space for copious waterings, and the soil may be beaten slightly with a fork in making up the bed, to prevent it from subsiding too much afterwards, and because it will have to serve as a stage for any other plants grown in front of the *Musas*. Having thus prepared accommodation for them, the next thing is the planting. This *Musa* produces suckers freely from the base of the old stems. Autumn or spring is about as good a time for planting as any, and suckers with one or two leaves are best. These should be planted sufficiently deep to cover the roots well, and five or six feet apart. This

The Banana.

will give plenty of head-room, and allow sufficient light for the successional suckers, as they spring up between, to take the place of those that have been cut down after fruiting. Good suckers will produce fruit within a year. If they are planted in August, say, and grown on in an ordinary stove temperature through the winter, and pushed on in spring as the days lengthen, with plenty of moisture, they will be fine plants by Midsummer, and will probably show fruit after that time, which will ripen in autumn and winter.

Fruit ripened in winter, however, is neither so large nor so good as that grown in a high temperature under the summer sun; and, as a supply of fruit of this kind is not likely to be desired or insisted upon all the year round, we should aim at having a supply from Midsummer to November. To accomplish this, the best plan would be to plant suckers in spring, not too early, and in August or September. Those planted in spring would be ready to throw up by November; but by keeping the temperature down to about 60° minimum and 70° maximum, and bottom heat the same, their fruiting could be prevented till December, after which time they might be

started with a higher temperature and more moisture. This would start the most mature plants into fruit at once, and the others would follow in succession, affording a supply from early summer onwards. During this period the autumn-planted suckers would be completing their growth, and showing fruit, as I have before stated, after midsummer, which would carry the supply on till winter.

The only attention needful while the plants are growing and fruiting is to keep up a steady bottom heat, starting at 75° or under, and raising it gradually to 85° as the days lengthen and sun heat increases; while the top heat may be kept at from 70° to 75° at night, and from 80° to 90° by day. Liberal waterings and syringings must be given, and the fruit must be well exposed to the sun and light. As a rule, they will produce more suckers than are required, and if these do not come up in the proper place, they should be lifted and planted in the place of those which have been removed after fruiting; but in doing so the old roots should be taken out, and several barrowfuls of fresh soil added where the new suckers are put in. In this way the succession is kept up without having more plants than there is either room or need for. When suckers are scarce, the old stems may be taken up with a root, and potted or laid in anywhere where they can have heat and moisture, and they will produce offsets in a short time. Sometimes the *Musa* is grown in tubs, and we have had to do with them in this way; but to plant out in the bed is by far the best way to secure vigorous plants and heavy fruit. It is, however, occasionally necessary to use tubs, in which case more attention in watering, &c., is needful. I have thus sketched briefly something like a practical method of cultivating this plant for its fruit. It is already grown in many establishments as an ornamental stove plant, and we now and then hear of chance instances of its fruiting; but it is seldom grown with that object in view, and it is for those who have the accommodation to do this to encourage the culture of such a useful, wholesome, and highly desirable fruit. J. S.

South American Fruit.—A traveller writes from Peru:—"Callao has also finished the dispersion of my childish faith in tropical fruits. Oranges, Bananas, and Pine apples are worthy to be compared with Apples, Pears, Peaches, Grapes, Strawberries, Raspberries, Figs and Currants. But as for all other tropical fruits, even Cherimoyer, I consider them like Papaws, Persimmons, May-apples, Ground Cherries, and other wild fruits of the Northern States, as curiosities rather than substantial good fruits. The Cherimoyer is not so good as its cousin the Papaw; it tastes too much like the May-apple, and it has too large a proportion of great seeds. It is very good, especially in the best specimens; but it is not so good to my taste as an Orange, and much inferior to a Peach or a Pear. The Pears on this coast, however, are, as far as I have met them, poor. The Grape is the only fruit of the temperate climes which I find here of really fine quality; and that seems good from Talcahuano, in latitude 37°, to this point in latitude 12°."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Raspberry Culture.—Being interested in the growing of Raspberries, I would be glad to know the most approved method of laying out a plantation of this fruit, both as to preparing the ground and weight of manure per acre; also, what fruit should be gathered from an acre of Raspberry canes.—M.

Outdoor Grapes.—I saw the other day some good bunches of Muscat hanging on a vine growing against the end of a black-bearded cottage at Enfield, and, on enquiry, was told that this vine invariably produces and ripens good crops every year. Is it usual for the Muscat to ripen its fruit out-of-doors in the south of England?—H.

Apples.—I have a fine orchard of these, from which I usually get plenty of good fruit; but, like my neighbours, I have this year very few. Singularly enough, however, my Ribstons are a good crop. Will some of your readers kindly say whether or not the Ribston generally is bearing better crops than other sorts this year?—Q.

Keeping Apples.—When there is a frost keep the Apples in a state of total darkness until some days after a complete thaw has come. In America they are frequently frozen as hard as stones; if they thaw in the light they rot, but if they thaw in darkness they not only do not rot, but lose very little of their original flavour.

The Peach Crop in America.—The papers in the Peach-growing districts say that the crop of this fruit will probably be the best, quantity and quality considered, that has been known for many years. But we venture to hint that a good crop of good Peaches will only be seen in the United States, when much more attention is paid to thinning the fruit, and otherwise regulating the energies of the trees than is at present the case.

MEMORANDUM OF THE FIRST COMMISSIONER ON
THE MANAGEMENT OF KEW GARDENS.*(Continued from p. 171.)*

THE DIRECTION OF WORKS.

ON the late First Commissioner of Works being appointed in December 1868 he commenced a new organisation of the department, by establishing, with the sanction of the Treasury, two secretaries, one to have control over the financial matters and general business, and the other with the title of secretary for works and buildings, for the superintendence of those services. The Assistant Secretary was appointed Secretary, and, having transacted the business of the Commissioners in superintending the horticulture of the parks and gardens in their charge, this duty was left in his hands. The secretary of Works and Buildings became the general adviser of the First Commissioner on certain questions connected with Works and Buildings, but no complete reorganisation of the department was effected. The consulting architect and surveyor of the Commissioners ceased to hold his office. At the end of the year 1869, the present First Commissioner was appointed, and on the retirement of the secretary of Works and Buildings, the First Commissioner proposed a more complete change, which, after communication with the Treasury, assumed the form of establishing a Director of Works. Mr. Galton, C.B., who had been an officer of Engineers, and employed as Inspector of Railways, and then as Secretary of the Railway Department at the Board of Trade, afterwards the Deputy Inspector General of Fortifications, and then as Assistant Under Secretary of State, at the War Office, was appointed the Director of Works. The First Commissioner issued instructions to the Director of Works regulating the performance of his duty, of which the following are extracts:—"The Director will examine all the estimates for works, buildings, maintenance, and repairs to be laid before Parliament, and bring under the notice of the First Commissioner all proposals which are new in character, or which are of questionable expediency. The Director will pay particular attention to the Treasury Circular of October 14, 1869, and to the Minute of the First Commissioner of December 11, 1869, and to any other general instructions in preparing the estimates. The Director will superintend the preparation and execution of all contracts entered into with the department for the execution of works and buildings, so as to see that the contracts are properly framed and duly performed, and all contractors' bills will be submitted to him for approval before payment. The Director will examine all indents and estimates for current works for maintenance and repairs, and no such works will be undertaken without his approval, except in cases of such emergency as to make a reference to him impracticable. The Director will give instructions, whether the works are to be carried on by contract, or departmentally, and in what manner tenders are to be made." These instructions were intended to apply to all works under the department, so that the whole might be brought under one uniform system of administration. No particular steps were taken by the secretary to explain to the subordinate officers the change that had been made; but it has been explained by the secretary that "Mr. Galton's appointment, and the purposes for which he was appointed, were so well known, that I did not think it necessary to make any special communication to Dr. Hooker." No question respecting the relations of the Director of Works to Kew Gardens came under the notice of the First Commissioner until the 7th of December 1870, when a report of the Director of Works on certain proposals of the Director at Kew was submitted to and approved by the First Commissioner. As the business did not appear to have been transacted in accordance with the general instructions, he added the following note, "works of this kind should be carried out on the responsibility of the Director of Works in future." The secretary underwrote it thus, "Write to Dr. Hooker;" a letter was sent, omitting the paragraph, and Dr. Hooker did not therefore receive this explanation of the effect of the changes which had been made in the administration of the department. The Director of Works carried on his duties according to his instructions, as shown in his report. Dr. Hooker, however, after a correspondence with the Director of Works, wrote an official letter to the First Commissioner on the 12th of July 1871, requesting the Board's instructions as to his responsibility connected with the warming of the plant houses, &c., with reference to the letter of the Board of the 29th of October 1867, before quoted, and expressing his opinion in favour of that arrangement. To this a reply was forwarded, explaining that under the new arrangements of the office, it appeared to the First Commissioner that the only manner in which the relations of the works and horticultural departments of the gardens could be properly maintained, was for the horticultural department to make requisitions to the office for such repairs, new buildings, or apparatus as might be, from time to time required, and for such requisitions as, on the examination of the Director of Works, might

be approved of, to be carried out under the supervision of one of the assistant surveyors of the department. On receiving this reply, Dr. Hooker forwarded a letter complaining, in general terms, of the acts of the First Commissioner, and claiming the privilege of bringing them under the cognisance of the First Lord of the Treasury. He was then requested by the First Commissioner to furnish the dates and particulars of the acts of which he complained. But having in his answer lunched out into various topics, without giving the precise information required, the First Commissioner contented himself with forwarding an official memorandum on the subject to the First Lord of the Treasury. An accident to one of the pipes having been the subject of complaint by the Curator, the First Commissioner instructed the Director of Works to inquire into it, in accordance with his duty as superintending officer of works. Dr. Hooker received notice of the proposed inquiry. The report of the Director of Works shows how necessary it is to place the entire works under the Works Department, and the First Commissioner gave directions accordingly to define more clearly the relations of the Director of the gardens to the officers of works, so as to obviate all future ground of dissension, or complaint; upon the principle that the botanist or horticulturist should make requisitions for what works are required, and that executive officers of works should be exclusively responsible for their execution, subject to the control of the Commissioners and of the Director of Works. The criticism of Dr. Hooker, the subsequent Report of the Director of Works, and a further Minute by the First Commissioner closed this business. The other works at Kew have been carefully revised and considered by the First Commissioner. On his first appointment he was requested to sanction a larger additional expenditure on a work which had been entrusted to the charge of the Director at Kew beyond the amount stated in the estimate. The Director was asked for an explanation, when it appeared that he had sent an explanatory letter, with his estimate, which had not been amended, so as to show the whole cost of the service; the proposed additional expenditure was thereupon sanctioned with the consent of the Treasury. Mr. Fergusson having suggested that a new staircase should be constructed at the back of the Museum, in substitution of the present one within the Museum, the assistant surveyor provided for it in his estimate for 1870-71, but as it was apparent to the First Commissioner that this would not remedy the difficulty and inconvenience that arose from a want of proper circulation of the public visiting the Museum, he struck the item out of the estimate. He afterwards directed the assistant surveyor to report on the construction of two staircases, one at each side of the Museum, to provide a more easy access and circulation, it being peculiarly within the province of the First Commissioner to determine what arrangements are best for the public convenience. On preparing the estimates for 1871-72 the assistant surveyor brought forward the estimate for the two staircases, but the First Commissioner finding the work more costly than was expected, and having regard to other expenditure, struck the item out of the estimate, with some others of minor importance. This project has not been renewed for reasons subsequently explained. The service for the supply of water at Kew, which embraces other places beyond the Gardens, was thoroughly investigated and reformed, under the guidance of the Director of Works, and improvements and economy thereby effected. Some other works of a trifling character were either dispensed with or improved. In the judgment of the First Commissioner, it is of great importance that the distinction and separation between the requisitions for services desired and the performance of them should be maintained throughout the administration of the Office of Works, so that the execution of works should be wholly under the supervision of the Director of Works. In the particular case of hothouses, to determine the nature of the climate required is the province of botany and horticulture; to provide the climate by artificial means is the province of the technical engineer, as is also the business of construction and repair. The science of generating and diffusing heat and of ventilation is not botanical, nor is it confined to hothouses, and any experience gained in one application ought to be made available for any other under the department. The Director of Works has to superintend the works for heating hothouses in various gardens and for heating buildings. He is peculiarly well qualified for the performance of this duty, and on a recent occasion he was expressly required to report for the Treasury on works of this kind in the Royal kitchen gardens at Windsor. The First Commissioner will not add to these remarks any verbal statements of Dr. Hooker, as he deems it more accurate to deal with the subject on the official records and the general principles by which the department should be regulated. The First Commissioner is convinced the least difficulty need not arise at Kew in carrying out the existing arrangements, which are necessary in the public interest, and he does not deem it right to

propose any changes. In consequence of the division of duties between the secretary and the Director of Works relating to the parks and gardens, the form of the estimate for that service was altered for the year 1871-72, to determine precisely the services under each, by introducing the sub-heads, "under the secretary," and "under the Director of Works;" but as this might make it appear that the Director of Kew Gardens was placed under an officer of the department, and not directly under the Commissioners themselves, the First Commissioner has expressed his willingness to submit the estimate to the Treasury in the form in use before the alteration was made. It is at the same time desirable to put an end to the somewhat irregular mode in which the estimates have been prepared, and communicated to the Director of Kew Gardens, and to provide in future that the assistant surveyor or Director of Works shall communicate with the Director of the Gardens, and obtain all the information that is necessary to enable them to form an opinion on any works, and that the First Commissioner shall, on the proposed estimates being submitted to him, make such inquiries of the Director of Kew Gardens as he may deem requisite; and after considering any representations the Director may desire to make, determine what estimates he will submit to the Treasury, and that as soon as the Treasury has settled the estimates, and laid them on the table of the House of Commons, they should be forwarded to the Director at Kew for his guidance.

MR. SMITH AND KENSINGTON GARDENS.

Having disposed of the general administration of Kew Gardens, the First Commissioner will notice one or two topics which Dr. Hooker has lately made the subject of remark and representation. Whilst the Bill relating to the addition of a part of Hyde Park to Kensington Gardens was before the House of Commons, Dr. Hooker and the Curator of Kew Gardens had been consulted about proposals to cut down or transplant some trees. The House of Commons voted a sum of money to carry out the work of adding to Kensington Gardens before the 31st March 1871. It was much delayed from various causes, and finally from the superintendent of the park falling ill of a sickness of which, after lingering some time, he died, so that at Christmas 1870 nearly the whole work remained to be done. As the season for completing the work was passing away, a telegram was sent on the 19th December 1870 requesting the Curator to meet the First Commissioner in Hyde Park at eight a.m. the next morning; this went direct to the Curator instead of to the Director. On the 20th December the First Commissioner made the following Minute: "Mr. Mann being reported too unwell to attend in the park, the First Commissioner directs that Mr. Smith be instructed to undertake the general superintendence of the works to carry out the approved plan. Dr. Hooker to be informed accordingly, and to arrange for Mr. Smith attending at the park as often as required. Mr. Smith will proceed under the direct instructions of the First Commissioner." Mr. Smith accordingly attended to make an inspection of the works, and give the requisite directions to the assistant superintendent of the park. On the 31st December the First Commissioner went to see Dr. Hooker at Kew to converse with him on current matters, but Dr. Hooker referred the First Commissioner to a letter he had written, which the First Commissioner had not seen, and assumed a tone which shortly brought the interview to a close. This letter, when afterwards seen by the First Commissioner, being, in his opinion, calculated to raise unnecessary and offensive controversy, the First Commissioner replied to it by a short Minute assuring Dr. Hooker of the real character of the transactions to which it referred. Dr. Hooker having again written on the subject, the First Commissioner forwarded a further Minute explaining that Dr. Hooker's letter was written under a misconception, and requesting him to obtain a report from the Curator respecting what had been done and could be done with the works at Kensington Gardens; and on this report being obtained, Dr. Hooker was informed that Mr. Smith's employment, which had, in fact, been suspended by a change of weather, should cease. Not having heard anything more of this transaction, the First Commissioner did not deem it necessary to enter into any further details. He had, in the first instance, supposed from Dr. Hooker's long connection with Kew Gardens, that he was perfectly able to manage them during the Curator's slight absences in visiting Kensington Gardens, but as soon as the First Commissioner was satisfied of his inability in this respect he put an end to the Curator's special employment. The First Commissioner regarded it as a question of public importance that any one employed under the Office of Works should make a considerable sacrifice to render whatever service could be performed to meet an emergency of which the First Commissioner was the proper judge, but he waived the discussion of the point then, and sees no occasion to revive it now. The First Commissioner would, however, point out, that in his view no person in the service can be justified in allowing any question by which he considers himself aggrieved to drop, and afterwards, when many of the facts and

circumstances which would have been fresh in the recollection of those concerned are imperfectly remembered, in reviving the subject as a grievance with new assertions. In this case the First Commissioner heard no more of Dr. Hooker's alleged grievance until the month of September 1871, when the First Commissioner declined to re-open the subject.

A "SURVEYOR OF PARKS AND GROUNDS."

At the end of 1870, the First Commissioner deeming the continued presence of the secretary in the office necessary, in consequence of the great and continuing increase of the business of the secretary's department, arising from development of the policy suggested by the First Commissioner to the Treasury, that all civil works, as opportunity offered, should be transferred to the department, and deeming it also expedient to establish a general comprehensive and continuous supervision over the expenditure on the horticulture of the parks and gardens under his charge, the First Commissioner considered it necessary that the arrangement by which the secretary was constituted an outdoor officer to superintend the parks and gardens should be revised, and he proposed to appoint a surveyor of parks and gardens who should undertake the secretary's duties in regard to them, but in a more technical manner. In any special question of style or taste in horticulture, the First Commissioner could still have had the benefit of the secretary's experience. Circumstances quite independent of Kew Gardens, rendered it necessary that this arrangement, if adopted, should be at once carried out, and the surveyor appointed. From the high character given by Dr. Hooker to the Curator of Kew Gardens, the First Commissioner selected him for recommendation for the office; but before recommending him the First Commissioner deemed it right to satisfy himself that the Curator possessed all the other qualifications which the First Commissioner deemed proper for the office, and for that purpose he had a long interview with the Curator, inquiring of him his views on every question affecting the supervision of parks and gardens; the result was highly satisfactory, but the Treasury declined to sanction the new office, and the proposal came to an end on the 29th December 1870. It would be unnecessary to notice further this subject, closed so long ago, were it not for the singular fact that Dr. Hooker revived this conversation after nine months, with the addition that the First Commissioner requested the Curator to keep it secret from him; this assertion being only a misapprehension of an observation of the First Commissioner that it was not necessary for the Curator to report, as the First Commissioner would himself communicate with Dr. Hooker on the subject. The First Commissioner would have been guilty of a dereliction of duty if he had recommended the Curator for promotion to an appointment without fully satisfying himself of the Curator's fitness, nor did he desire to use the Curator as a channel of communication with the Director on the subject.

(To be continued.)

THE LIBRARY.

THE BIRD.*

THIS is one of the series of beautifully illustrated works published by the Messrs. Nelson & Sons, some of which we have already noticed in the columns of THE GARDEN. There are, we believe, those who will pronounce it a transcendental and eminently unpractical book, as it is not in the least degree scientific or ornithological, but mainly sentimental. It is not a mere naturalist's description of any one bird or class of birds, such as is to be found in any of our numerous works on zoology, but a general consideration of all the ideas which the term "Bird" is capable of suggesting. In a spirit of the tenderest feeling, whose higher aim is to make mankind more thoughtful and humane, the author has well fulfilled his task of investing the bird-world with a charm and an interest which perhaps no other writer has ever expressed. He brings the bird before us "a sentient being, with its duties to perform, its mission to fulfil. We are shown what it has to fear and what to hope; what are the perils and what the consolations of its existence; how it possesses a faculty of combination and appreciation, of memory and reflection, which is something more than a cold mechanical instinct." Commencing *ab ovo*, the renowned historian presents us with a delightful picture of the nest-home, with the patient and self-inflicted captivity of the brooding mother during the period of incubation, and all

* "The Bird." By Jules Michelet. With 210 Illustrations by Giacomelli. London: T. Nelson & Sons.

the loving and attentive care of both parents for their helpless young. Then follow chapters on the power of flight, the instinct for migration, the triumph of song, and the various services rendered by many families of birds to the human race. In all these the author pleads powerfully for the protection and preservation of the birds, which the gardener is too much accustomed to consider only as his foes. No doubt it is sometimes provoking to lose a portion of one's Cherries or

other fruit in this way, but we ought to remember that, during all the rest of the year, the blackbirds and thrushes, which are mostly to blame in the matter, feed entirely on insects, and, from the numbers which they destroy, must render a service to our gardens to an extent of which we can perhaps form only a very feeble idea. We place the question here on the lowest ground of *quid pro quo* utility, and say nothing of the additional charm which our shrubberies and plantations derive

from the presence of the feathered songsters. Our own enjoyment, at least, of such places is always very much enhanced, when, while feasting the eye on the various forms of beauty presented by tree and shrub and flower, we can also listen to the sweet and cheerful strains of the happy choristers who sing unseen among the leafy branches.

For the birds of prey M. Michelet evidently has no love. In a gloomy chapter, whose title is "Death," he dwells strongly upon the unamiable characteristics of these tyrants of the air,

and assigns them a very inferior position in the scale of feathered perfection. "The agents of death, the murdering species, are here replaced very low in the hierarchy remitted to the rank which is rightly theirs. They are the most deficient in the two special qualifications of the bird—nest-making and song. Sad instruments of the fatal passage, they appear in the midst of this book as the blind ministers of nature's hardest necessity. The eagle, then, is in these pages dethroned, the nightingale reigns in his stead." For the harmless tribes, however, his affection appears to know no bounds, and the secret of this is manifest in the following extract:—

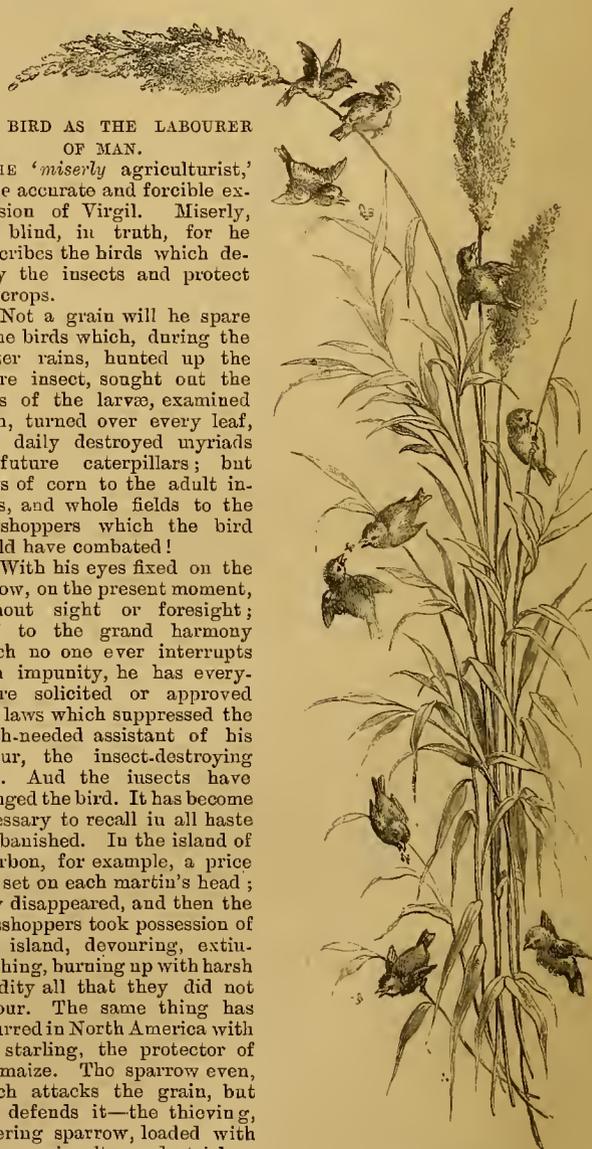

THE BIRD AS THE LABOURER OF MAN.

"THE '*miserly* agriculturist,' is the accurate and forcible expression of Virgil. Miserly, and blind, in truth, for he proscribes the birds which destroy the insects and protect his crops.

"Not a grain will he spare to the birds which, during the winter rains, hunted up the future insect, sought out the nests of the larvæ, examined them, turned over every leaf, and daily destroyed myriads of future caterpillars; but sacks of corn to the adult insects, and whole fields to the grasshoppers which the bird would have combated!

"With his eyes fixed on the furrow, on the present moment, without sight or foresight; deaf to the grand harmony which no one ever interrupts with impunity, he has everywhere solicited or approved the laws which suppressed the much-needed assistant of his labour, the insect-destroying bird. And the insects have avenged the bird. It has become necessary to recall in all haste the banished. In the island of Bourbon, for example, a price was set on each martin's head; they disappeared, and then the grasshoppers took possession of the island, devouring, extinguishing, burning up with harsh acridity all that they did not devour. The same thing has occurred in North America with the starling, the protector of the maize. The sparrow even, which attacks the grain, but also defends it—the thieving, pilfering sparrow, loaded with so many insults, and stricken with so many maledictions—it has been seen that without him Hungary would perish; that he alone could wage the mighty war against the cockchafers and the myriad winged foes which reign in the low-lying lands: his banishment has been revoked, and the courageous militia hastily recalled which, if not strictly disciplined, are not the less the salvation of the country.

"No long time ago, near Rouen, and in the valley of Monville, the crows had for a considerable period been proscribed. The cockchafers, accordingly, profited to such an extent—their larvæ, multiplied *ad infinitum*, pushed so far their subterranean works—that an entire meadow was pointed out to me as completely withered on the surface; every root of grass or herb was eaten up; and all the turf, easily detached, could be rolled back on itself just as one raises a carpet.

"In the exuberant fecundity of the Torrid Zone, the insects, those terrible destroyers of plant-life, carry off the superfluous. They are there a necessity. They ravage among the ever prodigious abundance of spontaneous plants, of lost seeds, of the fruits which Nature scatters over the wastes. Here, in the narrow field watered by the sweat of man, they garner in his place, devour his labour and its harvest; they attack even his life.

"Do not say, 'Winter is on my side; it will check the foe.' Winter does but slay the enemies which would perish of themselves. It kills especially the ephemera, whose existence was already measured by that of the flower, or the leaf with which it was bound up. But, before dying, the prescient atom assures the safety of its posterity, it finds for it an asylum, conceals and carefully deposits its future, the germ of its reproduction. As eggs, as larvæ, or in their own shapes, living, mature, armed, these invisible creatures sleep in the bosom of the earth, awaiting their opportunity. Is she immovable, this earth? In the meadows I see her undulate—the black miner, the mole continues his labours. At a higher elevation, in the dry grounds, stretch the subterranean granaries, where the philosophical rat, on a good pile of corn, passes the season in patience.

"All this life springs forth at spring-time. From high, from low, on the right, on the left, these predatory tribes, *échelonné* by legions which succeed one another and relieve one another each in its month, in its day—the immense, the irresistible conscription of nature—will march to the conquest of man's works. The division of labour is perfect. Each has his post marked out, and will make no mistake. Each will go straight to his tree or his plant. And such will be their tremendous numbers, that not a leaf but will have its legion.

"What wilt thou do, poor man? How wilt thou multiply thyself? Hast thou wings to pursue them? Hast thou even eyes to see them? Thou mayest kill them at thy pleasure; their security is complete: kill, annihilate millions; they live by thousands of millions! Where thou triumphest by sword and fire, burning up the plant itself, thou hearest all around the light whirring of the great army of atoms, which gives no heed to thy victory, and destroys unseen.

"Listen. I will give thee two counsels. Weigh them, and adopt the wiser.

"The first remedy for this, if you resolve upon fighting your foe, is to poison everything. Steep your seeds in sulphate of copper; put your barley under the protection of verdigris. This the foe is unprepared for; it disconcerts him. If he touches it, he dies or sickens. Yon, also, it is true, are scarcely flourishing; your adventurous stratagem may help the plagues which devastate

our era. Happy age! The benevolent labourer poisons at the outset; this copper-coloured corn, handed over to the baker, ferments with the sulphate; a simple and agreeable means of 'raising' the light *pâte*, to which, perhaps, people would object.

"No; adopt a better course than this. Take your side. Before so many enemies it is no shame to fall back. Let things go, and fold your arms. Rest, and look on. Be like that brave man who, on the eve of Waterloo, wounded and prostrate, contrived to lift himself up and scan the horizon; but he saw there Blucher, and the great cloud of the black army. Then he fell back, exclaiming, 'They are too many!'

"And how much more right have you to say so! You are alone against the universal conspiracy of life. You also may exclaim, 'They are too many!'

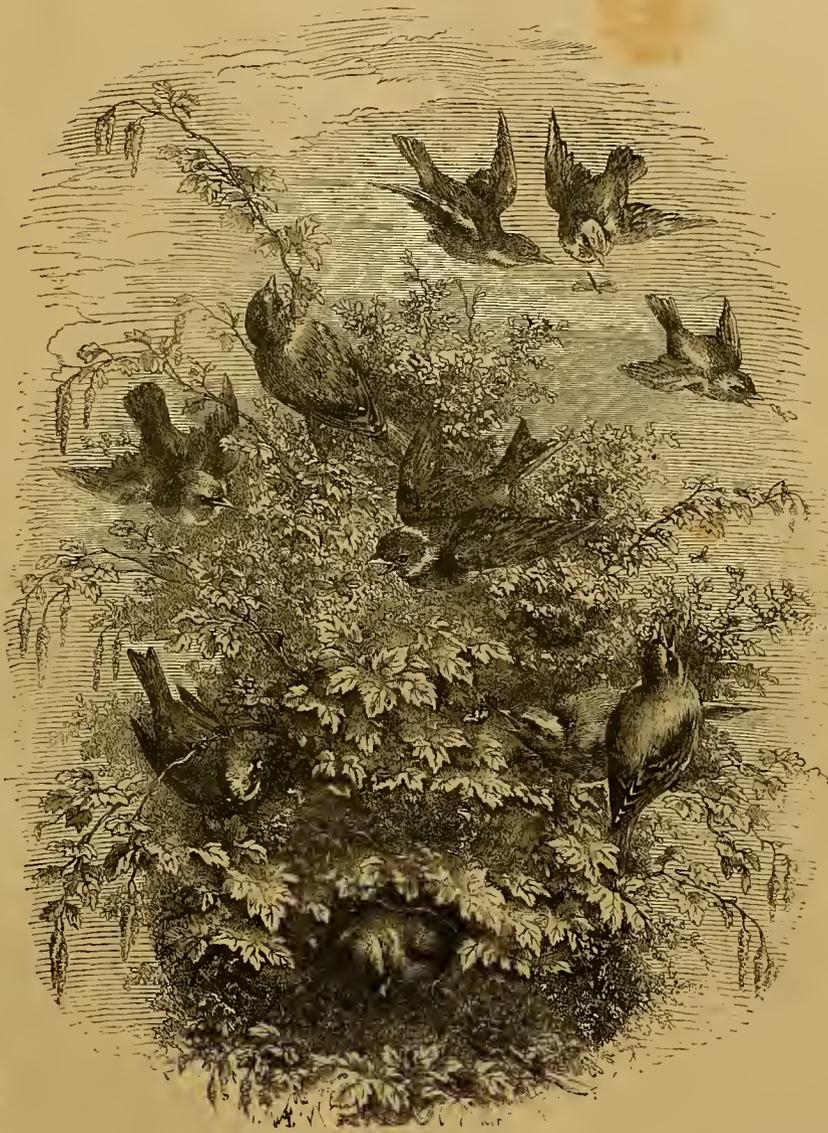

"You insist. See here these fields so full of inspiring hope; see the humid pastures where I might please myself with watching the cattle lost among the thick herbage. Let us lead thither the herds!

"They are expected. Without them what would become of those living clouds of insects which love nothing but blood? The blood of the ox is good; the blood of man is better. Enter; seat yourself in their midst; you will be well received, for you are their banquet. These darts, these horns, these pincers, will find an exquisite delicacy in your flesh; a sanguinary orgie will open on your body for the frantic dance of this famished host, which will not relax at least from want; you shall see more than one fall away, and die of the intoxicating fountain which he had opened with his dart. Wounded, bleeding, swollen with puffed-up sores, hope for no repose. Others will come, and again others, for ever, and without end. For if the climate is less severe than in the zones of the South, in revenge, the eternal rain—that ocean of soft warm water, incessantly flooding our meadows—hatches in a hopeless fecundity those nascent and, it may be added, ever greedy lives, which are impatient to rise, to be horn, and to finish

their career by the destruction of superior existences."

The foregoing shows how closely the author identifies himself with his subject, and how deep are his sympathies with all that concerns his beloved birds. We do not think that anyone can rise from the perusal of this book unimpressed by the high purpose and the benevolent tone which pervade it.

Of the illustrations, which occur on almost every page, we cannot speak too highly. By the kind permission of the publishers, we are enabled to give two or three specimens of them here, and, we may add, that the volume is in all other respects got up in a style fully in keeping with the exquisite finish of M. Giacomelli's admirable engravings.

THE HOUSEHOLD.

VEGETABLE DISHES IN AMERICA.

At a time when people are beginning to turn their thoughts to our never half-appreciated, never half-utilised, varieties of wholesome vegetable food, the following interesting article will repay perusal. It is written, as we can testify, by one thoroughly acquainted with the subject.

The beauty of American women—I beg their pardon, ladies—has become almost proverbial. Since the late ingenious Nathaniel Hawthorne denounced the English matron in terms scarcely so chivalrous as those in general use among American gentlemen when speaking of the fair sex, and praised to the skies “the trim damsels of our native land,” American beauty has made its mark in the world’s history. Dainty Transatlantic dames, glorying in tiny hands and stepping mincingly in almost impossible *bottines*, have compelled the aristocratic inhabitants of the “effete oligarchies” to own the power of a delicate intellectual type of beauty—often, alas! too evanescent. The middle-aged, and now unhappily obese, writer was once smitten “out West” by a pair of eyes, brilliant enough to penetrate through any known quantity of adipose tissue. The said eyes belonged to a very trim damsel indeed. Her knowledge—superficial, perhaps, but certainly showy—of all things in heaven and earth was positively astonishing. Her pace on the piano was wonderful; her grace as a “skatist,” and her proficiency in the “Dutch roll” were crushing. It must be confessed that her conversational talents, voluble as they were, were mostly of an interrogative nature. In the course of one short half-hour’s conversation with this gifted young lady, *et al.* seventeen, I was very thoroughly and completely pnt “through my facings” in theology, history, statistics, music, geology, painting, Mormonism, the comparative merits of America and the Old Country, the last new shape of bonnet, the last new novel, the Reverend and facetious Henry Ward Beecher’s last sermon, the prospects of the Erie Railway, Hans Breitmann, Bret Harte, Shakespeare, and the musical glasses. This brilliant combination of Venus and Minerva was irresistible. I thought it best to surrender at discretion.

Next day, however, my feelings received a shock as violent as it was unexpected. Among vegetables set forth for dinner was green corn, consisting of the tender ears of sweet corn—a peculiarly delicate variety of Maize. The “cobs,” carefully boiled, were served up in a napkin, and presented a very pretty appearance. My horror may be imagined when I saw the fair being of whose bow and spear I was the helpless captive seize upon a corn cob with her jewelled fingers, smear the vegetable object with pepper, salt, and butter, and then proceed—grasping the *corpus delicti* at both ends like a Pandean pipe—to gnaw the dainty nascent corn from its parent ear. I did not miss the next train. Much revolving these things, and groaning *imo sub pectore*, I rolled rapidly away eastwards, and entering into conversation with an intelligent person—much given to the chewing of tobacco—who was very anxious to know whether I was in dry goods or in oils, I dexterously turned the conversation upon green corn. The information candidly imparted to me was to this effect: That the habit of gnawing the corn from the ear was based upon a sound principle, *i. e.*, that a delicious saccharine substance adheres to the corn, and can only be thoroughly enjoyed by the gnawing process; that the effete inhabitants of the great city of New York, who preferred to cut the corn from the ear, were mere degenerate imitations of “Europians,” and that to such miserable creatures the true flavour of green corn was utterly lost. As a philosopher I was compelled to make the experiment, but without witnesses. It was not “a success.” The saccharine matter was there, as predicted, but the corn (or rather the tender husk thereof) inserted itself into the dental interstices in a singularly aggravating and pertinacious manner. Thenceforth I followed the practice of the degenerate New Yorkers, and cut the corn from the cob, mixed it with some stewed Tomatoes, and contrived to “worry it down.” It is recorded that a hungry Irishman tasting green corn for the first time was delighted with it, and handing the well-cleaned corn cob to the waiter, shouted, “Hurry up, and put some more Peas on my stick!” *Succotash* is a very agreeable combination of green corn and string Beans; or, still better, Lima Beans. The vegetables are first boiled, and then tossed in a stewpan with a noble piece of butter and a little pepper and salt. “New chums” are wont to hear many wonderful stories of the succotash tree. Vegetables of all kinds are much appreciated on the “other side.” Carrots, Parsnips, Turnips, and fresh young Beets are very welcome to all judicious eaters, and justly so, inasmuch as almost all vegetables, excepting green Peas, flourish under the burning sun of the New World. These latter, however, develop the woody fibre too rapidly, and the result is that it is almost impossible to procure—

except from your own garden—a dish of eatable green Peas; and at Delmonico’s, the French “canned” Peas are almost invariably preferred to “domestic” productions of the same kind. But Asparagus—possibly on account of its rapid growth near the sea—is excellent in quality and abundant in quantity. Lovers of this delicious and wholesome vegetable have ample opportunity for indulgence in *purée d’asperges*, *consommé aux pointes d’asperges*, *omelette aux asperges*, and, perhaps best of all, in cold Asparagus with a light salad dressing for breakfast. The last named meal is “a big thing” in America. A modest English breakfast, composed of dry toast, eggs and bacon, and watercresses, fades into insignificance when compared with the Homeric meal devoured in America at the early hour of eight or nine a.m. During the summer months Tomatoes (raw) are never absent, and are eaten either with salad dressing or with vinegar and powdered sugar. In the heat of burning summer an agreeable triple salad is often made in this wise: take a huge salad bowl or a punchbowl of dainty china, rub it with a Shallot, and then dispose in layers raw Tomatoes (not quite ripe), thin films of Bermuda pink-skinned Onions and sliced Cucumbers. The combination is delicious, and to a palate parched by an average temperature of 80° Fahr. is inexpressibly grateful. This triple salad is eaten with a light dressing of oil, vinegar, pepper, and salt, and is generally consumed as a *hors d’œuvre*. Cantaloupe and Musk Melons are also eaten as an agreeable preparation for the matinal meal, and are seasoned with a little pepper and salt. Breakfast not only begins but ends with fresh fruit, treated, however, in a somewhat different manner to the initiatory Melon or Peach. A sumptuous banquet of Melon, Spanish mackerel, beefsteak (without which no American breakfast is complete), outlets, eggs scrambled with thin filaments of smoked beef, muffins, stewed clams, and dry toast, is frequently concluded with a pile of Strawberries, blushing rosy red through their veil of luscious cream. No system is at once so agreeable and so wholesome as this one of consuming a quantity of fresh vegetables and fruit in the early morning; the ancient dictum that fruit is golden in the morning, silver at noon, and leaden at night, is quite sound, and should never be forgotten by those who would escape the demon of dyspepsia. Unfortunately, this excellent rule is only partially followed in America, and is utterly ignored at dinner, where it is not unusual for the shuddering spectator to behold a man devour a huge slice of Water Melon at the conclusion of his evening meal, wash it down with a huge goblet of iced water, and then fall—tooth and nail—upon a dish of iced cream, winding up the whole extraordinary performance with a cup of boiling hot tea. No stomach and no complexion in the world could survive a series of banquets such as this. The Egg-plant, or Aubergine, is extensively cultivated in America, and is susceptible of varied treatment at the hands of the cook. As in France, this fine vegetable is often stuffed and stewed, but is more generally eaten fried. The Egg-plant is cut into slices and steeped for some hours in salted water, and is then fried in butter. When well cooked it is very light and toothsome, but must be eaten while very hot, as it soon settles down into a tough and leathery condition. It is also often mashed and served *au gratin*. I will not plunge into the sublime mystery of *aubergines farcies*, as this excellent dish is well known to French cooks, and in the preparation of the *farce* and general treatment may be varied *ad infinitum*. Squash, more poetically designated Cymbelin, is a peculiarly American vegetable. It assumes the form sometimes of a Melon and sometimes of a French horn, and I believe that the Trumpet-squash is a prime favourite. These glorified Pumpkins must be carefully pared, cut in pieces, and the seeds and strings should be removed. They are then boiled in salt and water, and passed through a cullender. Served like mashed Turnips, they are exquisitely light and feathery, and bear about the same relation to that homely vegetable as a fleecy summer cloud to a good, solid, thick, old-fashioned November fog. Potatoes—funnily called “Irish Potatoes” in the very land of their birth—are consumed in all shapes; but it would be out of place for me to dilate upon the popular esculent abhorred of Banting.

There is, however, another vegetable very unlike Sir Walter Raleigh’s gift to Ireland, *i. e.*, the Sweet Potato. This tuber resembles a large Dahlia root, and is utterly dissimilar from the better known “Irish” variety. Sweet Potatoes may be either baked, boiled, fried, or best of all roasted in wood ashes. When cut open they present a fine golden, mealy appearance, and should be plentifully anointed with butter. Their excessively sweet taste makes them “impossible” when combined with any kind of meat; but eaten alone—with salt, pepper, and abundant butter as aforesaid—they are very good and satisfying withal. The coloured citizens of the United States are “death” on Sweet Potatoes. All kinds of green or string Beans are eaten with great gusto in the States, but the Beans must—like the proverbial Scotchman—be “caught” young, or the stringiness will be only too perceptible. Lima Beans,

however—whereof the Bean only is eaten—are altogether excellent, and are best dressed à la maître d'hôtel or à la Lyonnaise. Salsify—called oyster plant in America—is a truly delicious vegetable. Scraped, boiled, and fried in a fine batter—wherein there has been no stint of eggs—it is admirable, and, like very few things, bears out the promise of its name. It is not impossible that a blind man with a palate seared by a long course of "Bourbon" might mistake well-dressed oyster plant for the divine bivalve itself.

Sauerkraut has been rendered so popular in America by the Teutonic immigrants, that, like *lager-bier*, it has become a national institution. Even at Delmonico's, the very stronghold of delicate cookery, a *choucroute garnie* is by no means an unfashionable dish. It must not be forgotten that New York—or the German part of it rather—ranks as either the fifth or sixth German city in the world, so numerous is the Teutonic population. Whole wards are entirely tenanted by Germans, and signs bearing the magical words Lagerbier and Schweizer Käse stare one in the face at every corner. The truth of the maxim "cœlum non animum mutant qui trans mare currunt" is admirably borne out by the Germanic race. Where the German goes there go his manners and customs with him; his industry, his frugality, his tobacco, his music, his pleasure gardens, his sausages, and *schwartzbrod*, his eternal *kalbsbraten*, his herring salad, and, above all, his *sauerkraut*. To prepare the latter celebrated dish, take a dozen fine white winter Cabbages (I think they are called Drumheads in this country), and shred them very finely—every vestige of "stump" having been first carefully removed. [A machine like a huge Cucumber slicer is generally used for the shredding process when a large number of Cabbages is to be cut up.] Add to the shredded Cabbages a pound of salt, an ounce of juniper berries, and some whole pepper, and press the whole down as closely as possible in a cask; lay a cloth over it, then a wooden cover, and upon that a heavy weight. Let it stand in a warm cellar for two months, and it will be fit for use, and should then be removed to a cooler place. It is generally stewed very slowly with some gravy until quite tender, and is then served under pork, ham, bacon, or sausages, either boiled or broiled. When served with both sliced pork and sausages, it becomes the well-known and much-esteemed *choucroute garnie* previously referred to.

The confection of a herring salad is not a thing of the moment, but demands much previous thought and careful preparation. The theory of herring salad is based upon the solubility of fishbones in vinegar, and the "keel" must be "laid" by taking some Dutch salt herrings and laying them in a strong *marinade*, composed of seven parts of vinegar to one of oil, a clove or two of Shallot, plenty of sliced Onions, a Bay-leaf, and some whole pepper. In the course of a few days the small bones of the herrings will become perfectly tender, and may be unconsciously eaten with the rest of the fish, which—the backbone having been removed—should be cut into neat fillets. A salad is now made of cold boiled Potatoes (cut very thin), and the small green stuff called *kornsalat* by the Germans, and field salad by the Americans. It grows wild in every cornfield, and can often be obtained in Covent Garden Market. A slight *garniture* of finely-minced Parsley, Chives, &c., may be added; and the salad should be dressed with the usual four elements, *i.e.*, three spoonfuls of oil to one of vinegar, pepper and salt to taste. A portion of the herring should be mixed in with the salad, and the remainder of the fillets disposed neatly over the top, alternating with "streaks" of pickled Beetroot, and the white and yolk of hard-boiled eggs, all finely minced. Herring salad is deserving of very high commendation, for—like very few things in this world of sorrow—it is both cheap and good.—*Queen*.

Soyer's Breakfast Mushrooms.—We are indebted to Dr. Bull, of Hereford, for reminding us of the omission of the following capital receipt in our list of mushroom receipts last week:—Place some fresh-made toast, nicely divided, on a dish, and put the half-grown mushrooms, stemmed and peeled upon it; add pepper and salt judiciously, and put a small piece of butter on each. Then pour on each mushroom a teaspoonful of milk or cream, and add one single clove for the whole dish. Place a bell-glass over the whole (or an inverted basin will serve the purpose less elegantly). Bake for twenty minutes, and serve up at once, without moving the glass until it comes upon the table, so as to preserve the heat and the aroma, which on lifting the cover will be gratefully diffused. We have also to thank Dr. Bull for the original receipt of curried mushrooms, published in last week's GARDEN.

The Best Crap.—A Scotch nurse was out with a baby in her master's garden, and the gardener inquired, "Is't a laddie or a lassie?" "A laddie," said the maid.—"Weel," says he, "I'm glad o'that, for ther's ower mony women in the world."—"Hech, mon," says Jessie, "did ye no ken ther's aye maist sown o' the best crap."

THE FLOWER GARDEN.

THE SNOWFLAKES.

(LEUCOJUM).

THESE pretty bulbous plants belong to the same family as the Snowdrops, to which they bear a considerable general resemblance, but are larger in all their parts. The spring Snowflake

Spring Snowflake.

(*L. vernalis*) blooms about a month later than the Snowdrop, bearing its usually solitary flowers on stalks from 4 to 6 inches high. The fragrant drooping flower resembles that of a large Snowdrop an inch long, the tips of the petals being well marked with a green or yellowish spot. The leaves are ribbon-like, nearly $\frac{3}{4}$ inch across, and, after the plant has flowered, attain the length of nearly a foot. Its native habitat was long supposed to be confined to Central Europe, but within the last three or four years, it has been discovered "on the Greenstone

heights, in the neighbourhood of Britford," under circumstances which have led to the conclusion that it may possibly be indigenous. It is an excellent subject for rockwork, and no less valuable as a border plant, thriving in a light, rich, and well-drained soil, and is easily multiplied by separation of the bulbs.

The summer Snowflake (*L. æstivum*) is a much taller and more vigorous plant, bearing its flowers

Summer Snowflake.

on stalks from 1 foot to 1½ foot high. The flowers resemble those of *L. vernalis* in size, shape, and colour, but have the tips of the petals marked with green both inside and out, and are always produced in clusters of from four to eight blooms on each stem. The leaves, which are very numerous, are more than a foot long, and in shape are like the leaves of Daffodils. It blooms early in summer (in many places before spring has ended) and forms a pleasing object either in the the mixed border or on the margins of shrubberies, where, in company with

Solomon's Seal, the grace of its pendent flowers will perhaps be even better appreciated. Originally introduced from Central and Southern Europe, it has long been naturalised in England, particularly on the banks of the Thames between Woolwich and Greenwich. It thrives in almost any kind of soil and is readily multiplied by separation of the bulbs.

Another Snowflake (which was long supposed to be a form of *L. æstivum*, and is known in gardens under the name of *L. pulchellum*) is *L. Hernandezii*, a native of Majorca and Minorca. This grows to about the same height as *L. æstivum*, but has narrower leaves, flowers only half the size and usually not more than three on each stem; it also flowers nearly a month earlier. Being much inferior in its appearance to *L. æstivum*, it is not much cultivated. Those, however, who wish to grow it, can treat it in the same manner as *L. æstivum*.

HARDY FLOWERS IN 1872.

THIS year has been somewhat unfavourable for gardening, particularly in all that relates to tender bedding plants. A little more severity, and bedding out in the ordinary sense would have been impossible. The beds in Hyde Park were not, in many cases, filled till towards the middle of July, and soon the shortening days will put an end to their beauty. Most clear it is, therefore, that in such seasons as the present, even the poor ordinary blaze of colour which rewards the flower gardener for his great expense and trouble is scarcely, if at all, attainable. He wearily waits for good weather to put out his plants—till after the spring and early summer have past, and then they have not time to fill the beds before they are cleared off by King Frost, or are brought into the house to save them for another year. In such seasons how fares it with hardy flowers? Better than ever. Some might, perhaps, think that a season inclement for one class of plants would be so for another; but such is not

the case. Hardy plants have never been seen in such healthy vigour or abundant bloom as during the present season. Everywhere throughout the country, while the bedding out gardener has been bemoaning his fate, and gazing at his empty or half-covered beds, the possessors of anything like a collection of hardy flowers have been rejoicing over their exuberant beauty and long-continued bloom. By the term "hardy flowers" we mean no limited class, but a whole galaxy of beauties, which, we think, should be in every garden. All flowering shrubs we include under this heading. Mainly, however, it applies to the Anemones, Columbines, Harebells (Campanula), Delphiniums, Dicentras, Gentians, Day Lilies, Irises, Everlasting Peas, Linums, Lychnises, Evening Primroses, Phloxes, Primulas, Saxifrages, Sedums, Silenes, Statice, Veronicas, Violets, the hardy Crinums, Lilies, Daffodils, Scillas, Adonis, Anbrietias, Daisies, the Dianthus tribe in great variety, the Evergreen Rock Roses, Forget-me-Nots, and Pentstemons, and the numerous other ornamental flowers which are known as "herbaceous and Alpine plants." The reason of the great beauty displayed by these plants in a wet and cloudy season like that now passing away from us is not far to seek. They are mostly natives of the nplands of cool or temperate countries, where they are accustomed to abundant moisture in spring and early summer from snow water or copious rains, and to cool moist breezes on the high mountain meadows or copses or woods. Frost is to them no danger, except perhaps when very biting indeed, and then only to their young leaves in spring. Cold rains simply impart greater vigour and freshness. In our dry summers they sometimes suffer from want of water, as there are, as a rule, no provisions made in our gardens to guard against drought. But in our cold and bad seasons they will never fail us. Clearly then, no matter what our desires respecting "bedding out" may be, it is not well to neglect the very families of plants suited, above all others, to a cold and cloudy climate. Their presence need not prevent attention being given to beauties that require more attention as well as more sun.

Amarantus salicifolius.—This has answered the most sanguine expectations formed of it, at least about London. It is certainly one of the finest plants that has been added to our flower gardens for many years. Few things can surpass the elegance and grace of this plant when used as a centre to small flower beds filled with dwarf-growing plants. In Messrs. Veitch's Nursery, Chelsea, may now be seen groups of this Amaranth planted out of doors. Last year a border was specially prepared for it, and well enriched, where it grew strongly, but did not colour so well as expected. This year several groups and centre pieces to small beds are planted in light soil, and the same rich border again filled with them. Under both circumstances they have grown well, but those in the light soil have assumed a most brilliant red colour, the ends of all the branches and the tops of the plants presenting the appearance of great fiery red tassels; those in the rich soil have grown a little stronger than the others, but they have not coloured nearly so well as those in the poor soil.—W. F.

Delphinium bicolor grandiflorum.—The reference to Delphinium formosum by "A. D." (see p. 51) induces me to ask how it is that the plant in question, which has no doubt done good service in its day, should still continue to be grown, when a much better plant is available for like purposes. I allude to Delphinium bicolor grandiflorum. Probably as D. formosum is commonly raised from seed, there are various forms of it in gardens, but in the original plant, which I had direct from the raiser, the centre of the flower is tinged more or less with purplish blue. In D. bicolor grandiflorum, which possesses the same general habit, the eye is almost pure white, and a good spike is consequently far more effective than one of formosum. It comes true from seed, and is in every sense a most desirable substitute for the older plant. I avail myself of the opportunity of thanking "A. D." for his good opinion of Delphinium nudicaule. He is quite correct in stating that it should be strongly grown, and with a view to this, seed should be sown in autumn, the plants being kept as cool as possible during winter, to prevent premature flowering.—W. THOMPSON, Ipswich.

Rain-Proof Flowers.—At the head of these staud the herbaceous Phloxes. They are blooming with a continuity, a strength, and a purity of colouring this season that I have never seen equalled. The latter characteristic is very peculiar. The rain seems to wash the colour out of other flowers; it looks as if it laid more and fresher beauty on the Phloxes. All the strains seem the brighter and the truer the oftener they are washed, but especially the lilacs and the purples; these have a depth and a delicacy of tint quite unusual. Most of us know to our sorrow how easily most white flowers are tarnished by heavy rains; but the purest white Phlox bears the drenching downpour unruined and unspotted. The Golden Rod is

quite a different kind of flower, presenting but a tiny surface for water to damage, and it keeps its cheerful orange face bright and clean amid floods of rain. Dahlias, especially Floribunda nana, stand washing well; and Hollyhocks will bear a great deal of rain pretty bravely if the precaution is taken to thin the flowers on the spike for draining the water off those that remain. Among Pelargoniums, the only varieties that can endure the wet creditably are the ivy-leaved kinds and Mangles' variegated, which is the most beautiful and useful of all Pelargoniums for hedging and bouquet work. As for tricolors, bicolors, and bronzes, the leaves of most seem to lose colour by the drenching rain. The flowers of these and of nearly all the zonals prove traps for holding the rain, which quickly spots and mars the beauty and rots the substance of the flowers.—T.

HARDINESS OF PLANTS.

PERSONS interested in trying what plants will survive the winter in the milder parts of Britain, will probably find an aid in the following list of plants, which, in the winter of 1870-71, withstood without injury 15° Fahr. of frost in the open air in the Botanic Garden at Brest:—

Chloridopsis Blanchardiana Bambusa nigra viridi- glaucescens aurea violascens gracilis Arundinaria falcata Paspalum dilatatum Gymnorrhiza latifolia Pennisetum longistylum Cyperus asperifolius vegetus Commelina tuberosa Acorus gramineus Sauromatum guttatum Arum pictum Chamaerops excelsa humilis Tricyrtis hirta Xerotes longifolia Smilax horrida Dracaena congesta Dianella carulea Ruscus androgynus Aspidistra lurida Rhoda japonica Tritoma Uvaria media Burchelli Phormium tenax Zephyranthes candida rosea Hypoxis villosa Sisyrinchium laxum convolutum Morea iridioides Agave americana Iris sinbiata Pardanthus chinensis Anomatheca cruenta Babiana plicata Gladiclus cardinalis	Antholyza ringens Meriana Watsonia rosea All the Sparaxis, Ixias, and Tri- chonemas Tritonia aurea Wachendorfia thyrsiflora Sagittaria chinensis lanceifolia Aponogeton distachyon Chamaepeuce diacantha Helichrysum orientale Plagiis grandiflorus Pyrethrum cinerariifolium Borrhicia frutescens Erigeron quercifolium Eupatorium micranthum Aster carolinianus Cephalaria rigida Viburnum odoratissimum grandiflorum Paderia fucida Rhynchosper- mum jasminoides Convulvulus Cneorum mauritanicus Myosotis azoricus Cestrum roseum Lyctum afrum Solanum jasminoides Phygliis capensis Penstemon gentianoides Diplacis glutinosus Veronica Lindleyana salicifolia decussata Lippia chamedrifolia canescens citriodora Teucrium regium Prostanthera lasiantha Salvia Grahami caulicifolia Samolus littoralis	Rhododendron arborescens argenteum Azalea indica ledifolia Diospyros Kaki Olea europaea ilicifolia Osmanthus aquifolius Ilex Dahoon Thea sinensis Erodium geifolium Oxalis Deppei fabaeifolia versicolor Melianthus major Pistacia Lentiscus Rhus semi-alata Ungaria speciosa Cissus orientalis Iberis sempervirens Akebia quinata Kadsura japonica Illicium anisatum Urtica nivea Boehmeria cylindrica Muhlenbeckia nummularia Ampelgoum chinense Boussingaultia basellifolia Ercilia spicata Megasca ligulata Aralia papyrifera Sieboldii trifoliata Garrya elliptica macrophylla Aristolochia altissima Fuchsias, many kinds Zauschneria californica Lagerstromia indica Lythrum alatum Nesaea salicifolia Hovenia dulcis	Ziziphus sativus Palurus aculeatus Melaleuca thymifolia Eucalyptus resinifera viminalis Callistemon speciosum rigidum viridiflorum Leptospermum lanigerum Beckea virgata Myrtus communis Eucenia apiculata Eriobotrya japonica Photinia serrollata Raphioplepis salicifolia Neillia thyrsiflora Margaricarpus setosus Acacia sericea Anagyris fucida Cissus tomentosus Anthyllis Hermannia Medicago arborescens Psoralea glandulosa Erythrina laurifolia Edwardsia chilensis Cassia falcata Quercus glabra Cupressus lusitanica funebris Callitris quadri-valvis Thuopsis dolabrata Libocedrus chilensis Juniperus bermudiana Ephedra altissima Aristotelia Macqui Acanthus lusitanicus Eucomis punctata Richardia ethiopia Rubus australis Begonia discolor
---	--	---	---

These plants had no covering nor any protection whatever from walls, houses, &c., but were fully exposed in the open ground to all the rigours of the winter.

SOLANUM WARSCWICZII.

THIS very fine ornamental plant resembles *S. macranthum*, but has a lower and more thickset habit, and branches more at the base. The leaf-stalks and upper branches are of a red colour, glandular, and scaly, and the flowers are white and small. The stem is armed with strong slightly recurved spines, and both the stems and the petioles of the leaves are covered with a very dense crop of short stiff brown hairs scarcely rising above the skin. Among *Solanums* this is one of the best bedding kinds: isolated specimens, when well grown, also form striking objects. It is easily propagated by

Solanum Warscewiczii.

means of cuttings in early spring. When struck, they should be shifted as often as they require that attention. Thus treated they make good plants by the middle of May.

Manure for Roses.—I am a lover of Roses, and at the back of my cottage I have a strip of ground measuring only about 50 feet by 16, in which I have crammed over a hundred varieties. Last year they were magnificent; this season I have had an abundance of flowers, but few good ones, not from bad pruning, I think, but from want of manure; I can't give them the right thing without wheeling every bit through the house, which is held to be objectionable. If you, or any of your correspondents, will tell me what artificial stuff I can best feed them on, and how to use it, I shall be grateful. I may add that while I can grow Céline Forestier tolerably well, I cannot persuade Maréchal Niel or Boule d'Or to look at me. What is the secret?—G. B. [Will some of our readers kindly answer this question? With regard to the manure, Mr. Hole, to whom the above was sent, says: "If I am to advise Mr. B. in accordance with the course which I should myself pursue, were his position mine, I should say, 'send Mrs. B. to the seaside, and wheel some good manure through the house.'"]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Swainsonia Osborni.—This pretty New Holland plant thrives freely with me against warm walls planted in rich light earth. It is now very useful for cutting as well as a charming ornament to low walls.—J. M. D.

Aubrietia as a Wall Plant.—In Mr. Fennessy's nursery at Kilkenny I have just seen a wall almost covered with long wiry-like tufts of this plant rooted firmly in its surface. The effect in spring must be very beautiful. Imagine some of our old fern-covered walls or sunk fences draped with the tufts of lovely blue of the "purple Arabis," as they call it in London. To establish it we need only sow the seed in any mossy or earthy chinks in autumn or spring.

Wigandia Vigieri.—This seems to be the most vigorous grower, the hardiest, and therefore the most useful of the kinds in cultivation. In my garden in Warwickshire, it has now, notwithstanding the wretchedly cold and wet season, enormous leaves without a spot of any kind showing evidence of suffering. I raise it from seed sown in January, and grow it on quickly and well in warm quarters till May, when I harden it a little, planting it out as early in June as the weather will permit; it has a deep rich soil.—H. C.

Alonsoa Warscewiczii.—Let me recommend those who wish for a "new sensation" in bedding effects, to try this plant. Its colour is uncommon, very soft, yet very effective, being a delicate poppy-red. I picked out a large patch of it at a good distance off, upon the Dedham seed-farms in the end of July, and wondered what it could possibly be until I got quite close to it. In habit it reminds one of that old-fashioned plant called *Celsia*, and it is a remarkably free bloomer. It can be propagated either from seeds or cuttings. Clumps of it in a mixed border would be sure to give satisfaction.—W. T.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 174.)

TREATMENT OF THE YOUNG PLANTS.

As soon as the seeds are perceived to have germinated, a quite different mode of treatment must be employed. The young plants must be very sparingly and carefully watered. They must also be placed in a position close to the window, in order to receive the full benefit of the sunshine, from which, however, they should be shaded from 10 a.m. to 4 p.m. with some light material. A piece of paper supported by sticks some inches higher than the plants will be quite sufficient if there is no blind or curtain to the window. The more light and air the young plants receive, the stronger and more vigorous will be their growth. An immoderately long development of the stalk is the direct consequence of want of sufficient light and air. If this sickly development be not checked in time, the stem of the plant falls down and rots on the surface of the soil. This rotting of the stem is the most fatal disease of young plants, and often sweeps off entire sowings. It occurs most frequently in that stage of growth when the supply of nutriment in the seed has been consumed, and the young plant has to depend on the food which it receives through the roots. If the fibres of these are not perfectly developed, or if any condition necessary to their normal action be wanting, the roots perish, and the plant falls to the earth and rots. Want of light and air, too much moisture, too much heat, and a sour state of the soil, are among the most frequent causes of this rotting of the stem. This evil is so fatal to young plants that we shall devote some space to a more detailed account of its causes and remedies. We have seen that one of the causes is want of light and air. This may be produced not only by placing the plants too far from the window, but also by having them too thickly sown in the pot; and even when other conditions are favourable, these causes will be sufficient to produce the wholesale destruction of the young plants. Excess of moisture is chiefly caused by defective drainage in the pots or by too moist air. In room-culture moist air is chiefly to be apprehended when the glass coverings, &c., are not regularly removed in order to admit fresher and drier air. Too great heat is very injurious to annuals in particular, when sown in a warm room. The windows, therefore, should be occasionally opened to admit fresh, cool air, or the plants should be placed near a cool entry. Sour and unsuitable soil will of course be far more injurious to young plants than to old ones, which have greater powers of resisting such hurtful influences, under which the tender fibres of the young plants succumb, and the death of the plants follows. The selection of the soil depends, as has been already said, on the species of plant which is to be sown in it. But, as a general rule, highly manured soil should be avoided, as this is apt to induce the rotting of the stems. A good loamy soil, or a free sandy peat-soil is in general the most suitable kind for all sorts of seeds. The rotting of the stem may best be prevented by avoiding the causes which are favourable to it, but where it has once commenced, the safety of the plants depends very much on the quality of the stems, with regard to their property of throwing out fresh roots. If the plants stand too thickly together, some of them must be removed so as to leave free space for the rest. The plants removed should be carefully transplanted into a fresh pot, and if their roots appear long and spindly, and deficient in fibres, the ends should be pinched off. This will excite the production of fresh fibres. The plants are inserted into holes made in the soil with a piece of wood or the finger, to such a depth that the seed-leaves may be just above the surface. The object of this is that, when the roots of the plants are affected, fresh roots may be produced from the sound part of the stem under the root-leaves. But even when the plant is healthy in other respects, it is advisable to treat it in the same way, as these additional roots will secure for it a stronger and more vigorous growth. If the soil into which the plants are transplanted be moist, it should only be well watered from above when it begins to get dry. One plentiful watering after transplanting is necessary, in order to settle the soil evenly around the plant; but in the case of

small plants this should be done carefully, so that their root-leaves may not be covered with washed-up soil. With healthy seedlings, no further attention is necessary, after transplanting; but those which are suffering from stem-rot, and whose further growth absolutely depends on the formation of fresh roots from the stem, should be placed near the window and shaded from strong sunshine. Moreover, water should not be given until the dry condition of the soil shews that it is necessary, and the leaves only should be moistened with the "refresher" in hot sunny weather. Rare and valuable seedlings should, also, in the earlier stages, be covered with a bell-glass, which however, should be removed as soon as they have made some growth. This will serve to keep the soil moist by checking evaporation.

Where stem-rot is the result of too much moisture, the pot should be taken out of the saucer and the drainage-hole examined, to see whether it has become choked up. If the plants are covered with a bell-glass, it should either be taken off or plenty of air should be admitted by raising one side of the bell-glass on a wooden prop. In cases where a flat sheet of glass is employed to cover the pot, it should be raised in the same manner. If the plants have grown up spindly and drawn, but yet do not stand too thickly together, sand or powdered charcoal should be sprinkled on them, so that the stems may be buried up to the root leaves. Seedlings which have got the stem-rot, from being kept in too warm a position, may be treated in the same manner. The sand surrounding the stems will keep them cool. If the pot should be already so full of soil that this plan cannot be adopted, or when unsuitable soil is the cause of stem-rot, the plants should be transplanted into fresh and proper soil. Gilliflowers are especially subject to stem-rot when they have been sown in too light soil. A stiff loam is therefore the most suitable for these. The best time for transplanting seedlings in general (unless stem-rot or too thick a sowing renders it necessary at an earlier period), is when they have formed one leaf in addition to the seed leaves. They may be transplanted either separately into small pots, or several together in pans. Strong seedlings of some kinds of plants may have the soil mixed with manure. These plants are noted in the enumeration. After transplanting, the seedlings should be treated according to the special directions given with each kind in the enumeration. Only with respect to the first few days after transplanting, no further attention is necessary in the case of seedlings which have been so carefully removed that the ball has been unbroken, and which have had only the ends of their longest roots pinched off. But plants which have suffered in the removal must be treated for the first few days afterwards in the same way as if they had been transplanted on account of stem-rot. Seedlings raised in boxes are to be treated after the same rules. Kinds grown in heated boxes, which show symptoms of stem-rot, should be placed in the window, but palms and other plants which require a high temperature should be kept in the heated boxes until they have grown strong enough to be removed into the terrarium. —*Dr. Regel.*

(To be continued.)

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

Lycopodium dendroideum.—In New York, we are informed by Mr. Davidson that two thousand barrels of the tree *Lycopodium* (*L. dendroideum*) are used every year for bouquet making and forming wreaths. It is now principally brought from Maine, having become scarce in Connecticut and New York State.

Dracæna heliconifolia.—I find this fine species thrives well in my sitting room, a plant having been growing well in it for the past eighteen months. The leaves are fine in form, and of a pleasing green when kept free from dust by occasional sponging.—*G. W. K.*

The New Holland Pitcher Plant in rooms.—Mr. Ambrose Balfe grows this most interesting plant perfectly in his house in Westland Row. A specimen two years in the house is now in perfect health. It is covered with a bell-glass, and placed on a table near a window. We hope Mr. Balfe will some day tell us how he succeeds in growing so interesting and difficult a subject in a dwelling house.

Ivy as a Window Plant.—Londoners who cannot preserve their window pets, in place of striving to keep Geraniums, Fuchsias, &c., in life, should be contented with plants of Ivy grown in pots as pyramids, or other desirable forms, or suspended in baskets. It will thrive in any close room or alley; and if neat curtains or blinds contrast with the deep green of the Ivy, the effect is extremely pleasing. I noticed this particularly in house windows in Balcony.

DRYING WILD FLOWERS.

I AM anxious to make a collection of dried wild flowers. Will some one conversant in such matters kindly give some information as to the best mode of preserving them?—*M. L. W.* The following instructions, which are slightly modified from the remarks of the eminent botanist and collector Dr. Asa Gray on the subject, will, we have no doubt, supply all the information required:—

For collecting specimens, the only things needful are a small round trowel (or a large knife, strong enough to be used for digging up bulbs, small root-stalks, &c., as well as for cutting woody branches), and a botanical box or vasculum to hold the specimens collected. These boxes are made of tin, and in shape resemble a sandwich case, the lid opening for nearly the whole length on one side. They are made in various sizes; the most convenient and generally useful perhaps is one about fifteen inches in length by six inches across. A strong, well-japanned box of these dimensions will cost about half-a-crown.

The specimens collected should be either in flower or in fruit. In the case of herbaceous plants, the same specimen will often exhibit both at the same time, and both should be secured whenever it is possible. Of small herbs, especially annuals, the whole plant, root and all, should be taken. Of larger ones, branches will suffice, with some of the leaves near the root. Enough of the root should be retained to show whether the plant is an annual or a perennial. Thick roots, bulbs, tubers, or branches should be thinned with a knife, or cut into slices lengthwise.

For drying the specimens a good supply of soft and unsized paper—the more porous and bibulous the better—is wanted, together with some convenient means of applying pressure. All that is requisite to make good dried botanical specimens is to dry them as rapidly as possible between many layers or sheets of paper, to absorb their moisture, under as much pressure as can be given without crushing the more delicate parts. The best drying-paper is that which is made specially for the purpose, and which may be obtained from Mr. E. Newman, 9, Devonshire Street, Bishopsgate, London, E., but the softer sorts of cheap thick wrapping-paper will answer very well. The drying-pads are made by stitching from eight to a dozen sheets lightly together round the edges.

When the specimens are brought home after the day's collecting, each plant should be carefully laid out in a folded sheet of thin, smooth, unsized paper, the flowers and leaves being arranged in the position which they are to retain when dried. The folded sheet with its enclosed specimen is then to be placed between two of the drying-pads, and these again between two smoothly-planed boards of suitable size. Placing the whole on a table or on the floor, a weight of half-hundredweight or more is put on the upper board, and the specimens are so left until about the same hour next day, when the pads are to be removed and fresh well-dried ones put in their place, the boards and weights being also replaced as before. The pads which have been used are to be hung up to dry, so that they may take their turn at the next shifting. This process must be repeated daily until the specimens are no longer moist to the touch, which for most plants requires about a week; after which they may be transferred to the sheets of paper in which they are to be preserved. If very thick pads are used, it is not necessary to change them every day after the first two or three days. It is also to be observed that several pairs of pads, each with its enclosed specimen, may be placed between the same pair of boards, but in that case the weight applied to the upper board must be proportionately increased.

When the specimens are quite dry, they may be kept in folded sheets of neat and rather thick white paper; or they may be fastened on half-sheets of such paper, either by slips of gummed paper, or by glue applied to the specimens themselves. Each sheet should be appropriated to one species; two plants of different species should never be attached to the same sheet. The generic and specific name of the plant should be written in the lower right-hand corner, where the time of collection, the locality, the colour of the flowers, and any other information which the specimens themselves do not afford, should be also duly recorded. The sheets should be all of the same size. The herbarium of Linæus is on paper of the common foolscap size, about eleven inches long and seven wide; but this is too small for an herbarium of any magnitude. Sixteen inches and a half by ten and a half, or eleven and a half, is a more convenient size. The sheets containing the species of each genus should be placed in genus covers (made of a full sheet of thick coloured paper), which fold to the same dimensions as the species sheet, and the name of the genus is to be written on one of the lower corners. These should be arranged under the orders to which they belong, and the whole kept in closed cases or cabinets, either laid flat in compartments like large "pigeon-holes," or else placed in thick portfolios, arranged like folio volumes, and having the names of the orders lettered on the back.

THE ARBORETUM.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE EDIBLE-FRUITED CHINESE THORN (CRATEGUS LAYI).

THIS fine thorn forms a robust, free-growing small tree, from twenty to five-and-twenty feet high, with stout but not very numerous divaricate branches, and long spineless shoots, which are quite glabrous when young. It is a native of the northern parts of China, is perfectly hardy, and one of the earliest in leafing and flowering, and when loaded in the autumn with its large brilliant red haws it makes a fine display, and deserves a place in every pleasure ground, however limited. The leaves are large, broadly-ovate, tapering much to the foot-stalk, more or less deeply divided into five lobes, and regularly serrated on the edges, and when fully matured of a bright glossy-green above, quite smooth on both surfaces, and with footstalks from one to two inches in length. The

C. Layi—full sized leaf.

lobes of the leaves nearest the base are oblong-pointed, while those towards the point are broad and but slightly divided, but all of them are acutely serrated on the margins. The stipules, when present, are small, half cordate, and coarsely toothed on the outer edge, but they are mostly absent. The flowers are rather large, white, and produced in terminal, downy, acute-bracted corymbs, in the end of April or beginning of May. The fruit is large, globular, bright red, and when ripe, in October and November, agreeably tasted. Mr. Tradescant Lay, the British consul at Foo-chow-foo, the capital of the Chinese province of Fokien, who first sent seeds of this thorn to the Horticultural Society in 1844, says that "it grows in the province of Shan-tung, and that the fruit, when ripe in November, is dipped in syrup, stnek on rockets of straw, and sold in the streets of Ningpo and other northern towns." In this country it is one of the handsomest of all ornamental Thornes, and on account of its somewhat ample foliage it is easily distinguished from all other sorts, even when seen at a considerable distance off.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Calycanthus occidentalis.—This fine shrubby plant has been flowering abundantly for these past two months, planted against a wall in the gardens at Kew, and is still in great beauty. The flowers are of a dark red colour, and measure nearly 2 inches across. As a wall plant, it is worthy of more attention than it usually receives.—W.

Indigofera floribunda.—A specimen of Indigofera now in bloom in Mr. Cooke's unique and charming garden at Glen Andred, Sussex, has been flowering for nearly four months, and usually continues to do so till November. It is trained against a wall, and, considering its blooming period, beauty of bloom, and graceful habit, is second to no other wall plant we have; indeed, it is the best flowering wall plant with which we are acquainted.

Shrubby Potentillas.—Two of the best dwarf shrubs in flower at the present time are two species of Potentilla, viz., *P. dahurica* and *fruticosa*. They are capital subjects for margins of shrubberies or for rockwork. The flowers are yellow, and are produced in great abundance. The latter species has been in bloom for these past two months, and is yet, in many places, a mass of blossom.

Alnus glutinosa laciniata.—Only those who have been fortunate enough to see a really fine plant of this tree can form a true idea of what a noble specimen it makes, when it finds itself in a locality "to its liking." There is an exceedingly grand plant of it in Mr. Gassiot's ground at Carshalton, growing within 10 feet of the Wandle, upon soil only about 18 inches above the surface of the stream; its lower branches overhang the water, and are just high enough to walk under on one side, while on the other side they feather to the ground. The expanse of the branches measured 36 feet in one direction, and in other directions nearly as much; and the height was found to be 47 feet.—W. T.

Weeping Birch.—What is the greatest size to which this graceful tree will grow? Books give 40 feet as its height, but I think this is often much exceeded. A few days since I measured one, growing a few yards from the bank of the river Wandle, and I found it to be 53 feet high, and to cover a space of ground 48 feet across one way, and 42 feet another way.—W. T. P. [We believe that the Weeping Birch will grow as high as the normal form. There is a fine specimen of it in Elwanger & Barry's great nursery at Rochester, in the State of New York, which, though not very many years introduced from Europe, was quite 40 feet high when we saw it in 1871.]

The Ash-leaved Box-Elder.—Few trees have so striking an appearance in plantations as the variegated form of this species, which variety is commonly known under the name of *Acer Negundo variegatum*. The very marked difference in the shape of the leaves of the Ash-leaved Box-Elder, when compared with the leaves of other Maples, surely entitles it to removal from the genus *Acer*, and to be better known than it is under the name of *Negundo fraxinifolium*. It is described in some books as a "short-lived tree," which may have tended somewhat to prevent its being so frequently planted as it deserves to be; for the colour of its foliage is of such an unusual apple green that it forms a most pleasing contrast to the foliage of other trees. Books and lists agree in stating its height to range between 20 and 40 feet. It may therefore be of interest if I call attention to an unusually large specimen of it, which stands by itself at the junction of three roads near the Culvers Mill, on the River Wandle, at Carshalton; this tree is 66 feet high, and its branches overhang a circle of about 60 feet in diameter.—W.

THE KITCHEN GARDEN.

THE LATE IMPERIAL KITCHEN GARDEN.

WITH the object of turning to some useful account the *Potagerie* at Versailles, which has been for some years in a state of neglect, M. Joigneaux has laid before the Bureau of the National Assembly the project of a law for converting it into a public school of practical horticulture. By the provisions of this law the kitchen garden at Versailles is to be transferred from the jurisdiction of the Minister of Public Works to that of the Minister of Agriculture and Commerce, under whom it will assume another character as a national school of horticulture. All the pupils of this school are to be extern, and will be admitted only after passing an examination in such branches of knowledge as are taught in the primary schools. A Government regulation will fix the other conditions of admission. The profits on the sales of the produce of the grounds will be secured to the State, being placed in the hands of the Minister of Agriculture and Commerce, and the Minister of Finance. A supplementary credit of 20,000 francs will be opened, to enable the school to commence on the 1st of September. The establishment of this school would be a great national benefit, and would be attended with the happiest results. The pupils, after their two years' instruction, would return to their native villages, carrying with them improved methods and ideas on the subject of gardening, which their friends and neighbours, after ocular demonstration of their value, would not be slow to adopt. The inevitable result would be a general advance in the standard of horticulture throughout the provinces, with its necessary consequences of increased and better produce, and an improvement in the condition of the small *propriétaires*. We wish M. Joigneaux every success, and trust that his patriotic motion will receive a warm welcome from, and be passed with acclamation by, the "collective wisdom" of the National Assembly.

ENGLISH *v.* AMERICAN POTATOES.

SEVERAL articles have appeared in English gardening periodicals on this subject, all viewing the question in an English light; perhaps a few notes, therefore, from an American point of view may not be uninteresting. When the dollar-per-pomd Potatoes were talked and written about, probably English speculators expected to "strike ile" by investing in some, and would naturally praise their new investment, in order to induce English gardeners to take up the novelty. Doubtless many were disappointed, but the same would occur if we depended on the English varieties in this country. My experience confirms the fact that no crop varies so much under different soils and climates as the Potato; but, as a rule, on warm open soils the quality is superior to that of those grown on cold stiff land, and there is also greater freedom from disease. A case in point is the kitchen garden at Chatsworth, Potatoes grown in which were poor in quality, the soil being low and cold, but when grown on hot-beds under glass, the quality was so good that I was requested to send all I had for the family table in London. The garden at Teddesley Park had a light warm soil naturally drained, and the Potatoes grown in it were invariably fine and excellent in quality. What, however, an Englishman would consider to be a first-rate Potato is not to be obtained in this country, although those grown on the light sandy soil of New Jersey are much above the average. We can, however, grow first-rate Sweet Potatoes, a luxury not to be obtained in the cold damp climate of England. I obtained a few tubers from England of a number of the most popular varieties of Potatoes, including several of Patterson's Seedlings, Red Flour-ball, Racehorse, and Rivers' Ash-leaved Kidney, but from the first it was evident that they were not a success; the growth was weak and poor, and, when taken up, the tubers were small in size and number. When cooked, the Ash-leaved were better than any other Potato I have tasted here, and I intend trying them again, for we have no very early variety here, and the Ash-leaved is at least a fortnight earlier than Early Rose; the other varieties were an indifferent crop, and not good when cooked, the Flour-ball being the best, and Racehorse the worst. I gave them two years' trial. We find the Early Rose good in quality here, but from stiff land it is very bad, which accounts for the various opinions expressed by correspondents respecting it, and I have found other varieties just the same. I may say, however, that the Early Rose was a great acquisition for this country, but I never expected it to supersede, or even compete with, the many first-rate varieties already grown in England.

JAMES TAPLIN.

South Amboy, N.J., U.S.A.

Potato Disease.—When the crop is gathered, the apparently sound and good are selected from the diseased, either for immediate disposal or for storing by clamps or otherwise, but a portion of the latter in its early stage will invariably escape detection and be mixed with the sound, to their ultimate, if not speedy, ruin. Dry lime, pulverized, should be thinly sprinkled over every layer of the clamp, and the Potatoes—say in the spring, or when required for use or sale—remain invariably in the same state as when stored, the lime acting as a preventive of infection by contact. I should say a bushel to six pecks of lime would be amply sufficient for a clamp the produce of an acre and a moderate crop. This plan, which is by no means new, I have adopted both in Kent and Essex with unflinching success.—*R.*, in *The Times*.

Potato Starch.—It has been suggested to me by Mr. Gladstone that, now that we are on the eve of a Potato famine, I should give the widest publicity to the very simple method successfully introduced by the late Rev. Professor Henslow into certain villages in Suffolk and elsewhere for utilizing the diseased tubers. This method depends on the fact that the starch of the Potato is not affected by the disease, but retains its nutritive properties, and consists in rasping the peeled tubers upon a bread-grater into a tub of cold water. In a few minutes the starch will be found to have sunk to the bottom, and the diseased matter, woody fibre, &c., will be suspended in the water, and should be poured away with it. Fresh water should then be added, the starch stirred up, and again allowed to settle. Two or three of such washings will remove all impurities, and render the starch fit for use. If thoroughly dried it will keep for any time, and can be used as arrow-root, for puddings and cakes, or, mixed with flour, as bread. A flat piece of tin, prepared as a grater, may be had of a tinsmith for a trifle, and nothing else is required but a knife and a tub of water. But this temporary measure cannot be all that scientific resources may supply. Surely some method (by desiccation or otherwise) is applicable and available to the cottager, by which the sound tubers and the sound parts of diseased tubers may be so treated that they may be preserved for winter use; and I cannot doubt but that chemists will suggest such. Lastly, this season, which has favoured

the Potato disease, has also favoured an abundant crop of green food; and I would urge upon the clergy, medical men, and intelligent classes of the country parishes, combined action, in the way of precept and example, in introducing the Beetroot, the foliage of the Turnip, and various other vegetables as an article of daily consumption. Now, too, is the time for laying in stores of such nutritious articles as dried Haricots, Calavances, and various other Pulses and Beans which form the cheap, agreeable, and most nutritious food of the populations of many tropical countries.—J. D. HOOKER, in *The Times*.

American Rose Potato and the Disease.—Passing through a metropolitan nursery the other day, I saw a fine crop of this Potato that had just been taken up. The tubers were of good size and well formed, and out of a crop of fifty bushels, I was informed that a peck of diseased ones had not been found, whereas such kinds as the Shaws and Sandringham were very much diseased, and I do not expect that more than half a crop would be got of them. Perhaps some of your correspondents will kindly let us know if this Potato has thus escaped the disease elsewhere.—T. S.

GARDEN DESTROYERS.

TENTHREDO ADUMBRATA.

THE Pear trees in the neighbourhood of Dublin have been suffering severely from the attacks of a viscid larva, black, like a little leech, which seems glued and immovable on their leaves, and which eats the parenchyma from one of the sides, usually the

Slug Worms destroying Pear Leaf.

upper side, beginning not at the edge, but in the middle, and leaving the anastomoses of the smallest nerves and the epidermis of the underside intact, so that the leaves which it has attacked resemble a piece of very fine lace. It has a form and appearance which induced Réaumur to give it the name of *ver-limace*, slug-grub, or slug-worm. When at the end of the autumn it has acquired its full size, it has a slight resemblance, with its head drawn under the first ring and its tapering extremity, to a small tadpole. It is provided with twenty feet, but it is necessary to detach it from the leaf in order to see them. After having changed its skin four times the black gluey slimy surface disappears, and it becomes of a yellow orange colour; it descends the tree and makes for itself a cocoon with grains of earth joined by some threads of silk. It appears, however, to be difficult to rear the pupa into the perfect insect, for Boisduval says that he has put hundreds into pots filled with earth which he left out of doors during the whole winter, and yet never succeeded in obtaining a single perfect insect from them. Others, however, have succeeded, and it has been ascertained that it turns into a sawfly, named *Tenthredo adumbrata*, which is two lines and a quarter long, of a shining black colour, with the antennæ almost as long as the abdomen

The feet are black, with the anterior knees and legs of a red brown. The wings are dark.

The larva shows itself on the Pear trees at the time when the fruit is half or two-thirds of its proper size. The havoc which it commits on the leaves by destroying the parenchyma of course prevents the proper elaboration of the sap, the vegetation stops, the Pears cease to increase in size, and soon fall. There are several caterpillars of sawflies which resemble this species, and produce different kinds of sawflies, but they do not all undergo their metamorphosis in the same way. The *Tenthredo cerasi* of Linnaeus, for example, which has been confounded with this species, does not undergo its metamorphosis in the earth, but make a little cocoon between the leaves of the Cherry tree.

Similar slug worms occur in America, probably of different species from those in Britain. One in especial is mentioned by the American entomologist, William Peck, as having been for a long time a great plague in the United States, where it multiplied in a prodigious manner, on the Cherry, Pear, Plum, and Quince trees. There were upon every leaf from twenty to thirty larvæ. Many trees perished from exhaustion, those which resisted remained languishing, developed their shoots at the wrong season, and were struck with sterility. The advice given in America, when these insects are abundant on the fruit trees, is to sprinkle a little quicklime on the leaves. A. M.

A Plea for the Birds.—The bird question comes up as regularly as the "gigantic Mushroom" and the "large Gooseberry" (by the way I miss the Gooseberry this year; probably the late spring frosts nipped our old friend in the bud), but I should not notice it only that frequently there is a slight hint that our American cousins have not displayed their usual "cuteness" in introducing the sparrow into this country, and that at some future time they will repent, &c. This I doubt; at any rate it will not be in the present generation, and, when the trouble comes, I have no doubt there will be a remedy invented, at least greater difficulties have been surmounted. I know the annoyance from birds is very great in England, but is it not caused in a great measure by the almost total destruction of every bird or animal which preys on small birds, as mark the reports in the *Field*. I seldom take up a number of that journal without seeing one or more notes of how so-and-so shot such and such a rare hawk or owl, or the number his keeper trapped, and so on. This being done all through the country, the small birds are left masters of the situation, but even then they are not an unmixed evil, and they are no doubt a positive blessing in this country. A stranger need go no further than the avenues in New York and Brooklyn to see that.—JAMES TAPLIN, *South Amboy, New Jersey, U. S.*

Thrips and Red Spider.—I know of nothing which would be a greater boon to gardeners than a safe, easy, and certain recipe for killing thrips and red spider. I believe there is nothing equal to good tobacco paper for the first, but the difficulty is to get it good. I had some from a respectable source a short time back, sheets of strong brown paper, carefully folded and the outsides as black as pitch, but when unfolded to put into the bellows, it was very little better than plain brown paper, it would not even kill aphides, and of course would scarcely affect the thrips at all. I suppose it is not possible to obtain the juice at any price, else we might make it as strong as we liked, for I am persuaded, after fifty-six years' practice, that there is nothing like smoke for such insects as can be killed with it, as it is easily applied, while the various washes and powders are useless, because of the difficulty or impossibility of applying them. The point is to commence soon enough, for once let the insects get ahead, and then good-bye to handsome plants.—SENEC.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.

The Flower Garden.—This is a good time for visiting the gardens of our neighbours, in order to see what is most effective among bedding plants, which are now at their best. Such visits may afford a hint as to how we might improve our own next year. Arrangements both of plants and beds should be noted, as well as instances in which there is unusually good harmony of colour. In Battersea Park the variegated Maize forms a splendid front to some of the taller growing Cannas, which are further bordered with Geraniums and Heliotropes; Musa Ensete, singly on the turf, is a lovely and attractive object; Fuchsias, both tall and dwarf, seem quite at home, and we also noticed nice examples of New Zealand Flax and India-rubber plants, as well as of Palms of many kinds. The "cosy nooks" under the trees are tastefully filled with tree Ferns, tall broad-leaved Coccotholobas, India-rubber plants, *Monstera deliciosa*, &c.,

and under their shade are planted here and there the Bird's Nest and other ferns, the whole growing on a carpet of the common greenhouse Selaginella (*S. Kraussiana*). The rock-gardens also present some admirable features, for here one may see what would suit his taste best for forming a hardy "carpet," also several of the best and most attractive plants to mix together, either in small masses or as isolated specimens. Other good examples of flower gardening may be seen in Victoria, Hyde, and Regent's Parks, the gardens of the Zoological Society, and in many of the private gardens round London. One of the most neatly and tastefully arranged is that in front of the conservatories at Sion House.

Conservatories.—Of the gayer blooming greenhouse climbers *Lapagerias* at present are among the finest; they love open material in the way of soil, and plenty of water when growing and flowering. Passion-flowers, Cobaeas, and other quick-growing climbers are kept within bounds by a free use of the knife, and clean by means of good syringings in the evening, using occasionally a little weak manure water. Asters in pots are at present very gay, as are also zonal *Pelargoniums*, which, in order to prolong their flowering season, have all seed-pods picked off as they appear. Among flowering plants foliage ones are often mixed, and with excellent effect. The dark-leaved *Coleuses* and *Iresines*, and the white *Centaureas* and *Cinerarias*, form as pleasing contrasts indoors as they do out. Indoors they can be made even more available, for along with them we can group Citrons and other evergreen shrubs, Lilies of various sorts, Fuchsias, Balsams, *Vallotas*, choice annuals, and an innumerable host of other variegated-leaved and handsomely-flowered plants. *Begonias* are now found to be very useful, especially the herbaceous kinds. *Heaths*, *Cytisus*, *Coronillas*, and other hardwooded plants are still kept out of doors on beds of ashes. Cacti, Aloes, *Fouquierias*, &c., are likewise out, or if not, they are exposed to the sun as much as possible, so as to make them a little hardier than they might otherwise be for the winter. Even a little browning by the sun is not objected to.

Stoves.—In these both temperature and atmospheric moisture are being gradually lessened, the main object now being to have the plants well matured before the short days arrive. But little shading is now requisite. Plants, however, having fleshy roots, such as *Musas*, *Palms*, &c., are still allowed a tolerably large amount of water; not even in the depth of winter are they allowed to become quite dry. Several of the *Begonias* that were cut over some weeks since are pushing up afresh nicely, and will be found most useful in another month. Of these, none is better than *B. spatulata*, for it is not only a free bloomer but its large pure white flowers make it also desirable. *Allamandas* growing vigorously receive good supplies of manure water at the root; there is little fear of too much luxuriance, as at this season every forthcoming eye shows a good truss of bloom, which, unless well nourished, will not open large and fine. *Adiantum Farleyense* is kept shaded with pieces of paper or canvas in addition to the ordinary shade of the stove or fernery. Filmy Ferns are also well shaded and gently sprinkled overhead every day, and even twice on particularly warm days. Should the weather be showery, it may be injurious to sprinkle them unless they are getting dry.

Indoor Fruit Department.—Pines from which fruit has been cut, but the suckers of which are hardly fit to take off, are either left a little while longer in the pit in which they fruited, or are taken out and placed in a vinery or some other warm house, where they will be sure to produce good suckers. As soon as the necessary supply of suckers is obtained, they will be taken off and potted; little water, however, is given to the suckers until they begin to emit fresh roots. Plants that have flowered have a few pieces of good fibrous loam placed around their necks, so as to induce a free emission of young healthy roots, which can be fed by occasional waterings with weak manure. Young pot vines intended for next year's fruiting are being ripened by leaving a little air on night and day. Peach and Nectarine trees continue to be well syringed. Those that can be placed out of doors are put out, care being taken to obviate sudden changes at the root. Fig trees on which fruit is swelling receive thorough waterings, which are gradually reduced as the fruit begins to ripen. Strawberries for forcing are being shifted into larger pots.

Hardy Fruit and Kitchen Garden Department.—Sowings of the American Red Stone and Strap-leaved Turnips are being made, as they stand a little later in the ground than the White Stone or Yellow Finland kinds that were sown a fortnight ago and are now being thinned. Early Potatoes are being harvested; the largest are separated from the others for culinary purposes, the second sized ones are kept for seed, and the smallest are given to the pigs. Potatoes are well dried in the sun before storing. The main winter crop of Spinach is being sown, and the first sowing is being thinned out a little. Early Celery is being earthed up as required, but late

crops, which generally get only one earthing, are kept untouched. Lime is dusted over the plants, to prevent the ravages of slugs. Any suckers springing from the plants are removed. Hardy Hammersmith and Brown Cos Lettuces are being sown on sheltered ridges to remain throughout the winter; they come in useful after the late crop is finished, and before the early Lettuces come in. A second sowing of Winter Onions is made in case of any mishap befalling the other. Endive is sown on sheltered ridges; such plants as are fit are planted out, and those that are ready are blanched. For blanching some prefer just to place a piece of matting over the crowns, as it does not break or crush them. Leeks in ridges are being earthed up, mixing at the same time some thoroughly decayed manure with the soil. Seedling Parsley is being thinned, and some crowns transplanted where they can be protected during winter. Netting is stretched over such Pear trees on walls as have fruit on them, to prevent damage being done to it by wasps or birds. All runners are removed from young Strawberry plantations as they appear.

NURSERIES.

Indoor Department.—Glass houses are being repaired, so as to have them in trustworthy condition throughout the winter. Heating apparatuses are also undergoing thorough examination. Dipladenias are being increased by means of layers. One or more plants are placed in a shady part of the stove; the several shoots are loosened from the trellises; little pots are then filled with a peaty compost and finished with a layer of silver sand on the surface; these pots are then so placed that the joints of the shoots may be placed on them and held in position by means of a stone or peg. Under one shoot may be placed several pots, keeping one or two eyes clear between each pot. Epiphyllums are being grafted on Pereskia stocks, on which they seem to take freely, and do not require nearly so much attention, heat or shade, as many other plants. Camellias and Daphnes are also being grafted in close propagating frames in intermediate houses. Conifers are being propagated by means of cuttings of the young wood; on some, however, a small piece of the old wood is retained. These are placed in close frames or under hand-lights in cold frames, and are well shaded. Gloxinias struck from leaves are being potted off singly as they become fit. Old plants are gradually dried off, as are also Achimenes which have done flowering. The ordinary stock of hardwooded greenhouse plants is still kept out of doors.

Outdoor Department.—The training of young fruit trees is still being actively proceeded with. Budding is not everywhere yet finished. There is still a good flow of sap in the branches, and the bark opens freely, but in most cases branch budding was done first, leaving for the last such plants as were intended to be worked on or near the base, where the bark continues longer in a suitable condition than on the branches. Evergreen shrubs are being lifted for purposes of sale, and also for making room for other things. Most people, indeed, contend that this is the best of all seasons for transplanting evergreens. The ground is naturally warmer and moister at this time of year than at any other, and therefore, as soon as the roots are consigned to their new quarters, they begin to grow, consequently the plants get well established before winter, and are in a good position to break away vigorously next year. Cuttings of herbaceous plants, lately struck in pans in frames, are being potted off singly into thumb-pots, placed in cold frames, and kept well shaded for a time. Seed of all kinds is now being secured. What is ripe is gathered, and what is not is being placed under the most favourable circumstances for its maturation. Balsams are found to yield seed from the most double kinds as well out of doors as in pots, and in order to induce them to ripen seed with more certainty, the side-shoots are removed, leaving only the main or central stem. Lilies of the lance-leaved section are being looked over. The ground occupied by summer annuals is now mostly free from them, and is being manured and dug for biennials and perennials raised from seed this summer, to be transplanted therein. Many of the biennials have only just come up; but strong-growing ones, like Hollyhocks, Digitalis, &c., which were sown earlier, are now transplanted into good rich ground, there to remain until there is room for moving them to their permanent or blooming quarters.

MARKET GARDENS.

In these fruit gathering now occupies attention. Vegetable Marrow plantations are still yielding enormously, and the plants are growing rapidly. Stones or half bricks are laid on the rambling vines to cause them to root at their joints, the withered leaves are removed, and in some of the earliest plantations it has been found necessary also to remove some of the shoots. Custard Marrows are also bearing freely. French and Runner Beans are both yielding heavy crops; the former are past their best, but the latter are still in excellent condition. Gherkins, though past their best, are still producing a few. Lettuces that were planted between lines of Savoys

are being cleared off, the Savoys now requiring all the space. Celery is growing apace, and has not from the first received a check from the want of water. To the earlier crops a little earth is added each time they are hoed; a main earthing has just been applied to the first planted. Lettuces on the ridges between the earlier crops are being removed for market. Endive is being planted out in sheltered places a foot or fifteen inches asunder, in lines two feet apart, the top of the late Celery ridges being mostly occupied with this crop. Between the rows Strawberry plants are planted; the Endive, however, will be removed before the Strawberries require the space. Any plants of Carrots, Parsnips, or Beet, running to seed, are immediately removed from amongst the rest, and are either thrown away, or, if not too far gone, the sprouting shoot is removed, and the roots brought to market. Herbs are being cut and dried. Red Cabbages are good this year, and where the greatest distances have been left between them, they are by far the largest. Cabbage plants set aside for seeding are now cut down as the seeds become ripe. Tomatoes are kept well tied to stakes, keeping them on the sunny side of the support, and pinching off any laterals that may happen to appear. Some of the most favoured, in regard to position, have ripened a few fruits, but fruit-bearing is not yet general. There is, however, promise of a heavy crop of good fruit, should we have good sunny weather to ripen it. A nice supply of Spinach is now being obtained from sowings made some weeks since. Late sowings have just come up, and are being thinned and cleaned by means of short-handled narrow hoes. The trampling to which they are subjected in the operation does not seem to harm them much, for in a day or two they appear as fresh as ever. Cabbage plants sown in 4 feet or 5 feet beds, are now forming their fourth or sixth leaves, and are being cleaned in the same manner. The hoes used for this sort of work are about an inch and a half in width, and are very useful for loosening the soil as well as thinning the plants. Beds of Cauliflower plants are being sown in warm sheltered places, where they will remain until hard frosts are likely to come on, when they will be lifted and placed under hand-lights or in frames. Some, however, prefer leaving them exposed a little longer, as they think they stand the winter better by being hardened a little.

LAW NOTES.

Injuring Flowers and Shrubs.—At the Marylebone police court the other day, Charles Davis, seventeen years old, was charged with wilfully damaging flowers and shrubs in Regent's Park. James Scarfe, a park-constable, saw the prisoner stamp on a bed of valuable plants, and after walking over some other flowers, throw himself at length on some laurels and break several shrubs. Mr. Mansfield ordered him to pay a fine of twenty shillings or go to prison for fourteen days.

Marland v. The Lancashire and Yorkshire Railway Company.—This was an action against the company for the non-delivery within a reasonable time of eight bags of onion seed intrusted to them for carriage from Bury to Liverpool, by reason of which the plaintiff had lost his market and suffered damage. The defendants had paid £5 into court as sufficient to cover the loss, but the plaintiff claimed £156. He was, however, subjected to a very damaging cross-examination both with regard to the value of this seed and other matters, and the jury stopped the case, and gave a verdict for the company.

A Right of Common Case.—Mr. Justice Mellor was engaged the other day at the Dorset Assizes in hearing a right of common case. The nominal litigants were Davis v. Thorne, but the dispute was in reality between the Earl of Shaftesbury, Lord Normantou, Lady Bingham, and other freeholders, on the one hand, and Mr. Fryer, lord of the manor of Verwood, in Dorset, on the other hand. The right of common and the right of turbary were involved in the case. The common in question consists of 1,500 acres. The plaintiff Davis was a tenant of Lord Normantou, and before certain enclosures were made—now the subject of litigation—he could drive his cattle at once from his homestead on to the common. But by these enclosures—made by the defendant—he had been shut out, being compelled to go on to the turnpike road in order to get to a portion of his farm, thus putting him to very great inconvenience. A great number of witnesses came forward, it being argued from the evidence that by the making of the enclosures the lord of the manor had enriched himself, while the rights of the freeholders had been destroyed. The case ended in a verdict for the plaintiff, nominal damages forty shillings. This will prevent the formation of any more enclosures on the common by the two hundred tenants at present living there.

What is an Inch of Rain?—An English acre, says the *Builder*, consists of 6,272,640 square inches; and an inch deep of rain on an acre yields 6,272,640 cubic inches of water, which, at 277,274 cubic inches to the gallon, makes 22,622.5 gallons; and as a gallon of distilled water weighs 10 lbs., the rainfall on an acre is 226,225 lbs. avoirdupois. As 2,240 lbs. are a ton, an inch deep of rain weighs 100,933 tons, or nearly 101 tons per acre. For every 100th of an inch a ton of water falls per acre.

THE GARDEN.

“This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE.”—*Shakespeare.*

THE SIX OF SPADES.

CHAPTER XX.

Mr. Chiswick on Bedding-out (concluded).

“You know, my friends,” Mr. Chiswick resumed, after one of those pauses which were made in our readings, not only for the refreshment of the reader himself, but that the other members of our small society might converse upon the subject of his lecture, “you know that I have a brother, who is a huntsman; and, as I hear from those who have seen him in the field, and as I read in the *Field* itself, a very good huntsman too. Well, we had the other day a grand debate, which of us had the most difficult place to fill. ‘To deserve the name of a huntsman,’ says brother Will, ‘you must have a brave heart in a strong body, and a clear head in your velvet cap. You must know the natural history, character, habits, and capabilities of the three most intelligent animals in all creation (not excepting a large number of human beings, such as drunkards, gamblers, and vulpicides), the horse, the hound, and the fox. You must know every wood, plantation, spinney, and gorse covert, every field and fence, every “earth” and drain in the hunt. You must be such an accomplished horseman, you must have such nerve, and hauds, and seat, that you can either make your horse do his hest at full gallop over a big’un or a brook, or cau make him creep step by step down, through, or up that “very nasty place indeed,” in which there is only just room for him and for you. All the while you must be able to think on horseback, to observe the line of your fox, to watch the working of your hounds, and to restrain your “field;” to be calm when your fox, just breaking into the sweetest country you have—all grass, and the next covert five good miles away—is headed back by a young lunatic, racing outside for a start, and makes for the woodland clays; to be serene when some fiend, in the form of a sheep-dog, chases him, and the scent is lost; to keep your temper when that chiropodist, on the rushing chestnut screw, rolls over the best hound in your pack.’

“To be a good gardener,” I made response, “a man must be well acquainted with geology, entomology, and meteorology (expecting that these long scientific words would make a strong impression upon William’s mind, I must confess to some disappointment upon hearing a low whistle), with botany, chemistry, geometry, drawing, and colour. He should have Solomon’s knowledge of all trees, from the Cedar to the Hyssop. He should know not only from what countries his trees, shrubs, flowers, fruits, and vegetables—all things under his care, whether pleasant to the eye or good for food—are brought, but the climate, soil, and situation in which they naturally thrive. He must have both a refined taste and a persevering industry, both mental and manual skill. He should be as strong in health as the hardy Norseman, for that is a perilous life which takes men in the winter-tide from the 75° of the stove to the 20° of the outer air. And with all these qualifications he must submit sometimes to be regarded as a mere brewer of wood (of tallies and pea-sticks) and drawer of water, for his plants. He must be conscious that he is occasionally considered by his fellow creatures (alas! it may be by those whom he serves), only as a useful attendant on the cook. He must be prepared, again, to hold himself responsible for all the inclemencies of the weather, and the injuries done thereby. Like the great patriarch, he must bear the loss, whether drought or frost consume. He must listen at times to strong hints and suspicions that he has layed, incubated, and hatched all the red spiders, mealy bugs, thrip, scale, beetles, aphids, slugs, snails, grubs, and caterpillars, which gnaw the gardener’s heart.”

Our single wicket match ended in “a draw.” We came to no agreement on the main question. On one point, nevertheless,

we were quite unanimous, namely, that a large number of individuals set up to be huntsmen and gardeners, because they possess one or two of the many qualifications required. “I know a fellow,” said Will, “who considers himself quite A 1 as a huntsman, because he has won two or three steeplechases, and can ride eight stone ‘with notice.’ When there are spectators, he is looking for a big fence, instead of looking at his hounds, and his main object in life appears to be to ‘pound the field.’ Half the determination to kill his fox which he exhibits in his efforts to kill himself, would make him a great reputation. Another thinks himself qualified to carry a horn because his father and his uncle hunted hounds; and a third feels himself quite equal to take command of ‘the Quorn,’ because he has been for four seasons one of the most incompetent whips in England.* There are plenty of them, who can do one thing well; who can do well, or at all events look well, in the saddle, who can buy horses, corn, and meal, breed hounds and bring them out in first-rate condition; but a huntsman! why, I tell you, Frank, you would have to chuck fifty such chaps as these into a furnace, before you could get enough of the real metal to make one Will Goodall!”

“It is very much the same,” I rejoined, “with gardeners. A youth has hardly been foreman for a year before he esteems himself competent to preside at Chatsworth. He thinks himself a grape grower, because he has thinned a few large bunches of grapes; a plantsman, because he has produced a huge *Caladium* or *Coleus*; a master in arboriculture, because there happens to be a nice *Wellingtonia*, planted when he was a baby, in the grounds of the place in which he lives. Nay, not a few of our older gardeners quietly ignore, or openly depreciate, important branches of their art. ‘We don’t go in for fruit, we are not great here in kitchen stuff, our soil is too light for this, or too heavy for that,’ they say.

“Now it’s all very well for a gardener to have a speciality, to try for excellence and perfection in some one department (and I would advise him to do so where his range is limited), always stipulating that nothing of consequence shall be neglected; but never, so long as I am in the flesh, and one blackball excludes, shall that man be admitted into the ‘Six of Spades,’ who contracts and confines his admiration to some particular pursuit in horticulture, and sees no charm beyond; who, excelling in fruits, takes no notice of flowers, or succeeding in stove and greenhouse plants, will hardly look at the outdoor garden, the rosery, the fernery, the alpine or herbaceous plants. The true gardener loves them all, and wherever or whenever he finds either beauty or cultural skill, there and then his heart is glad. But I fear that there are many who declare themselves to be passionately fond of a garden who only care for a little bit of it; and I have seen those who were ‘never tired of gazing on the darling flowers,’ signally defeated in single combat with an honest, humbug-hating yawn. I could tell you of a pretender who came from one of the principal places of England to see another yet more beautiful than his own, and when he found that there were no Orchids, he passed through the spring gardens as quickly as though he was late with a letter of importance for the post, and then spent the rest of his day in an adjoining public-house. You say, Will, that many a man blows the huntsman’s horn who knows but little of his craft, and I say that many a man plays *Flora’s fiddle* who is master of but one tune.”

This conversation came into my thoughts when I began to consider what I should say to you of Summer Bedding-Out; and you will accept it, I hope, as an illustration of a fact, which all true gardeners must acknowledge and deplore, namely, that while this branch of modern horticulture absorbs with many of our brotherhood an undue proportion of their time and thought, by many others it is not justly appreciated, and by some is absolutely denounced. I have spoken of the first of these extremes; let me say now, referring to the latter, that the man who can look upon beds, well arranged, of these summer beauties, bright with a soft splendour when the evening sun is low, and feel no admiration nor enjoyment,

* “I’ve a very unpleasant duty to perform this morning,” said a noble and sarcastic master of hounds to his friend, as they rode to the meet. “I’ve an apology to make to my two whips. I told them the other day that they were the two biggest fools in England, and I’ve been out since with Lord —’s hounds, and seen two bigger!”

does not realize my idea of a florist. What, think you, would our gardening grandfathers say if they could return to gaze on those glowing groups of Stella and Cybister, Lady Constance Grosvenor, and fifty other scarlet, carmine, and crimson Pelargoniums; the roseate blushes of Christine, Rendatler, Amaranth, Miss Rose Peach, &c. (how much do we owe to Donald Beaton in the past, and to John Pearson and others in the present, for these beautiful bedding flowers!); the Verbena's rich, kingly, purple; the Lobelia's brilliant blue; the dwarf Ageratum's softer shade of gray; the Calceolaria's golden sheen; the clear, bright yellow of the Pansy and Marigold; the deeper hues of the Gazania, Tagetes, and Tropæolum; the varied tints of the Petunia, from white to velvety purple, pale pink to dark maroon—how could they look on these jewels, in their setting of emerald, this exquisite picture, framed by dark, glossy evergreens, or (as at beautiful Hardwicke), by tall, graceful arches of Honeysuckle and the climbing Rose, and not confess that the scene before them, as a brilliant display of floral beauty, outshone their brightest dreams?

"Will you be good enough," I hear it said, in satirical tones, by some resolute opponent of the summer system, "to invite your gardening grandfathers to stay the night; and will you oblige me by supposing that, while their ghostships are in bed, one of those little incidents, not uncommon in this country, which go by the name of thunderstorms, shall 'drench our steeples, drown our cocks,' and play upon your bedding out? And will you favour me with your opinion, as to what those ancient florists would say, when they looked out o' window next morning, and saw how your fine-weather sailors had weathered the storm, how, with heads drooping, and all the colour gone from their faces, they crouched, limp and draggled, naked and crippled, wrecked and broken-hearted, gazing in mute despair upon all their torn and faded finery, floating upon the green sea around?"

I must honestly answer, that if the beauty of summer bedding-out depended upon the flowers to which I have referred, these ghostly, gardeners would say, that they preferred a thousandfold the simpler prettiness, which no rains could mar, of their hardy and varied plants, and shrubs, and trees, to the brilliant, but ephemeral splendour which delighted them yestereve. I should feel, speaking as a cricketer, that the satirical opponent had made a clean hit for six, and that there must be a change of bowling. Messrs. Flower and Bloom being too much alike in style, I should substitute for one of them Mr. Leaf. The alternation is irresistible.

Since my first acquaintance with the bedding-out system, and I have known it almost from its birth, I have always advised, and introduced into my own garden, a large proportion of those plants which have beautiful foliage, simply because, being weather-proof, they are attractive from first to last, from the time of their appearance in the beds to their removal for safety, or destruction by frost. When Koniga and Cerastium, and "Flower of the Day," and "Manglesi," and "Golden Chain" (still one of the best) Geraniums (we knew not then in our terrible ignorance why they should be called Pelargoniums, and I have been told that there are still two or three gardeners in very obscure localities, who are not quite clear on the subject), when these were our only foliage plants, I used them largely; and well I remember the joyous welcome, which we gave to Bijou and Alma, Cloth of Gold and Golden Fleece (I once saw it designated as "Golden Fleas"), as more recently to the lovely Flower of Spring, Crystal Palace Gem, and May Queen.

Not with the same unmixed gratification do I recall the introduction of the darker foliage. I obtained seed of Perilla nankinensis, before any of my neighbours knew of it, and I determined to galvanise them in the succeeding summer with a shock of astonishment, and to turn them green with jealousy. I turned myself black instead. My vaulting ambition over-jumped itself by several feet, and I came down in the mud before my tittering friends. You know how sparingly this melancholy leaf must be used, and you will therefore readily imagine the effect produced in a garden of which it was made the predominant feature, appearing in more than half the beds. I can only compare its aspect to that of one of the ugliest objects with which I am acquainted, and, I venture to add,

most unchristian also, for it suggests neither faith nor hope—the top of a funeral hearse.

After this, as you know, our gardens were enriched by the far more cheerful and charming leaves of the Iresine and Amaranth, Coleus and Beet. These are grand additions, and are most effective in combination with the bright summer flowers, and in contrast with other foliage plants, such as the gold and silver leaved Pelargoniums, the Centaurea and Polemonium (both introduced as bedders by Mr. David Thomson, then at Archerfield), the Pyrethrum and variegated Veronica. Some complain of difficulties in cultivation, but no plants are more easily propagated from cuttings than the Coleus and Iresine, or from seed than the Amaranthus, Beet, and Perilla. I always throw in a good trowelful of rich manure, when planting the Iresine and Amaranthus (of the former, Lindeni and acuminata are very superior to Herbstii), harden off my Coleus Verschaffeltii carefully and gradually, and plant the second week in June. In adverse weather, Coleus, Amaranthus, and Iresine may look unhappy, and even lose some leaves at first; but if their feet are kept warm, in the socks which I have recommended, they will soon recover. Beet and Perilla require no coddling.

Who forgets his first interview with Mrs. Pollock—how he gazed in fascination upon those lovely tricolor leaves, then worth half-a-crown apiece? The story was told of an enthusiastic florist, that he noticed one morning a sudden and mysterious alteration in the demeanour of his wife. She was cold, sullen, and morose. Insisting upon an explanation, he was reluctantly and tearfully told that he had been murmuring in his sleep fond praises of "a Mrs. Pollock!" Mrs. P., Lady Cullum, and Sophie Dumaresque are the best in this section for planting *en masse*.

And then the bronzes—very striking and effective when properly grown and grouped, and, so far from being injured by our summer storms, smiling upon us more brightly than ever, when they have been "washed, just washed in a shower." I have been very successful with Luna, Mrs. Longfield, and Beauty of Calderdale—but I now prefer, with much gratitude to the raisers, Messrs. Downie, Laird, & Laing—Crown Prince, Imperatrice Eugenie, Lord Rosslyn, and Marquis of Lorne. The variegated Ivies, too, are also extremely pretty, whether as beds or as edgings. Mr. Grieve, of Culford, showed to me, at the Provincial Exhibition of the Royal Horticultural Society at Birmingham, a new variety, having a black and gold horse-shoe on a bright green ground, very distinct, and sure to be popular.

I did not mention, when speaking of the darker foliage, the Oxalis and the Alternanthera, because the former seems too earth-like in colour to be effective in beds, and the latter has been, with me, capricious and weakly. I also think that Echeverias and Sempervivums are more appropriate to the rockery than to the summer garden, and I am inclined to believe that a snug nook in the same habitation will prove most suitable for that exquisite gem, Mesembryanthemum cordifolium variegatum, with its bright little purple flowers peeping out from its golden leaves.

And these latter words remind me how many of our plants with variegated foliage have beautiful flowers as well, to wit, of Pelargoniums, Flower of Spring, May Queen, Silver Nosegay, Bijou, Cloth of Gold, Crystal Palace Gem, Golden Fleece, the Tricolors, and Bronzes, and Ivies.

Let me therefore advise that in the summer garden foliage and flowering plants be intermixed, in circles, diamonds, panels, à la pin cushion, and in other designs, so that the one may support the other, both in prosperity and in adversity, both in wet weather and in dry.

When I have added to this, dig well, dung well, put out plants few and good, rather than numerous and scraggy, but such as will eventually quite cover your beds, note down the defects of this year's arrangement, that you may correct them hereafter, keep your ears open when visitors come, and your eyes when you go a-visiting,—I have only to thank you for your kind patience, and to resume my pipe.

S. R. H.

THE magnificent specimen of Musa Ensete in the Palm house at Kew now shows a strong flower spike. This noble Banana has been planted in its present position a little over two years.

NOTES OF THE WEEK.

— THE Madresfield Court Grape is now fruiting finely in a cool orchard house at Chiswick. Considering its excellent Muscat flavour and general fine character, the fact that it can be grown so well in an unheated house makes it a peculiarly valuable fruit.

— THE grandest plant of *Lapageria rosea* we have ever seen in a pot is now in flower at Mr. Williams's Victoria Nursery, Holloway. It is trained over a large balloon-shaped trellis, and is literally covered with flowers of the largest size.

— WE learn that Messrs. E. G. Henderson have received some striped and otherwise beautiful forms of *Gentiana excisa* from the Alps. These are great novelties among Alpine plants, and we therefore trust that they will not fail to grow and increase, as they would prove precious additions to our rock-garden flora.

— AT the last Crystal Palace Flower and Fruit Show, Mr. Keyncs, of Salisbury, distinguished the 50th anniversary of his career as a floral exhibitor by sending in probably the finest collection of Dahlias ever shown at that place. They were of great size, perfect symmetry, and of every variety of colour. The judges were unanimous in congratulating him on his great and deserved success.

— THE Chinese Quince, which is cultivated as an ornamental shrub, is stated, by a correspondent of a southern American paper, to produce fruit in Georgia so large as occasionally to weigh over three pounds. Instead of being of a greenish colour, as further north, it is of a lemon yellow in the south. It is coarse-grained, dry and woody everywhere, and of no economical value.

— WE have to thank Messrs. Rivers, of Sawbridgeworth, for an opportunity of examining some of the new Nectarines of which we spoke in our last issue, and have only again to call attention to their remarkable distinctness and goodness of quality. Intending planters will do wisely to bear them in mind this season. We hope to notice them individually in due time.

— MR. S. T. KELSEY, of Pomona, Kansas, has a contract to plant trees, 160 acres every 10 miles, with the Atchison, Topeka, and Santa Fé Railroad, for 300 miles. He furnishes the trees and takes care of them for eight years, and has for compensation 640 acres at each place, including the 160 acres planted. The object of the Railway Company is to add to the value of its remaining lands, to ascertain and show the time required to obtain a remunerative forest, the best methods of cultivating, and what trees will succeed best.

— *Polygonum cuspidatum* is the most stately and at the same time the most graceful hardy perennial now in blossom. The stems rise from 6 to 9 feet high, and are laden with branchlets strung with small racemes of creamy white blossoms. The plant is most valuable, and well deserves good treatment and a good position. It is seen to most advantage as an isolated tuft on the grass in the pleasure ground. It loves rich deep soil. Fair specimens of it may now be seen in Battersea Park and in the gardens of the Royal Botanic Society, Regent's Park.

— ANOTHER fatal accident has happened to a market gardener's workman, Daniel Lewin, of Rainham. He fell asleep on the waggon, fell off, and was crushed to death under the wheels. He had then been up eighteen hours, and would not have reached market for two or three more. Occasionally he got to bed at 9 and rose at 4 or 5 o'clock, but when the cart went to market he had to work late. He was sober. The jury returned a verdict of "Accidental death," seven jurors being strongly of opinion that men should not be worked for so many hours.

— WE have received from Messrs. Fisher, Holmes & Co., of Sheffield, some noble blooms of a new variety of *Lapageria*, named by them *rubra grandiflora*, concerning which they state that as many as between two and three hundred blooms have been open on a plant at one time, although constantly reduced for purposes of propagation. The flowers appear to be of a deeper colour and to have longer tubes than those of *L. rosea*, whilst the leaves are longer and possess more substance than those of that sort. It seems indeed to be altogether a freer flowerer and a stronger grower than *L. rosea*, and therefore a great acquisition to the handsomest type of indoor climbers.

— THE old historic site of Say's Court, remembered through its associations with the ancient family of Evelyn, and as a residence of the Czar Peter, during his stay as a shipwright at Deptford Dockyard, is now undergoing a transformation, eight of the 15 acres of vacant ground around it having been set apart as a public recreation ground for the use of the people of Deptford. Mr. W. J. Evelyn, the present representative of the family of the author of the "Diary" and "Sylva," has generously borne the expense of clearing, draining, levelling, and preparing the land for its ultimate purpose,

and the other day visited and inspected the works now in progress, which are under the superintendence of Mr. Evelyn Liardet. It is understood that should his gift be used in a manner satisfactory to him, Mr. Evelyn will probably allow the remaining portion of the ground to be used similarly. The old Manor House of Say's Court is to be restored, and will be an interesting object to future visitors, the remains of an old tree planted by Peter the Great being still shown near it, in a portion of what was once the garden of Say's Court.

— THE *Warrington Guardian* states that Colonel Wilson Patten has announced his intention of giving £3,000 towards the public park now being purchased for Warrington.

— THE Marquis of Westminster has issued an invitation for a picnic to be held in the grounds of his country seat, at Cliveden, to all those masters and mistresses who are recognised by Government as teachers in the numerous schools on his lordship's London estate, including Westminster, St. George's, Hanover Square, Pimlico, and other districts.

— ON Tuesday night week, Kate Black, aged two years, wandered into the road and was run over by a cab. It was proved at the inquest that the sad accident was one of many which resulted from the absence of children's playgrounds. After hearing the medical evidence in the case, the jury returned a verdict of "accidental death."

— AT a flower show held a few days since in the town of Haverfordwest (the first exhibition of the kind ever held there), a very handsome tree of the common Myrtle was sent for exhibition. The plant, which was said to be over 100 years old, at one time belonged to Catherine Warren, the intimate friend of John Wesley, and grand-daughter of Catherine Wogan, of Wiston. The plant was exhibited by Admiral Stokes.

— A PLANT of *Psophocarpus (Dolichos) tetragonolobus*, a Leguminous climber, is now fruiting in a stove at Mr. Parker's Nursery, Tooting. The flowers are of a beautiful sky-blue. The plant has about two dozen pods on it at present, each of which measures twelve inches or more in length: they are large and quadrangular, each angle being very deeply serrated. To lovers of plants remarkable for the singularity of their fruit, this will be a desideratum.

— *AGAVE geminiflora*, a very graceful Aloe, not uncommon in a small state in many good collections of plants, and usually called Bonaparte's juncea, is about to flower in Mr. Williams's fine collection of conservatory plants in the Victoria Nurseries, Holloway. The specimen throwing up the bloom-spike is one of the largest and finest we have seen, and is worth seeing, even if not in its present interesting condition. The plant has very rarely flowered under cultivation.

— AMONG the less common edging plants now used about London, the best is decidedly *Coprosma Baueriana*, a finely variegated glistening evergreen, which may be pegged down so as to form very neat edgings. The leaves are of such a fine shining green and the variegation so rich that the plant reminds one of *Arabis lucida variegata* when in fine condition, though the leaves are much larger than those of the *Arabis*. Good examples of it may be seen at the Wellington Nurseries, and also at Mr. Herbst's Nursery at Kew.

— THERE is a recently imported batch of unusually large specimens of the Elephant's Foot plant (*Testudinaria elephantipes*), now in the Victoria Nurseries. The huge bulb-like rhizomes are dragged off their native plains without roots or stems. Placed on sphagnum, in a moist stove, they soon however begin to emit thick white roots from the lower surface, root at once if potted, and soon commence to send up their twining stems as if nothing had happened.

— THE *Standard* throws out a suggestion that a large farm, or several farms with a variety of soils, should be acquired, either permanently or for a period, on which well-directed attempts should be made to solve the problem of the best means of Potato cultivation. All methods hitherto suggested should be fairly tried, and new ones applied for counteracting the disease. It then goes on to particularise a number of experiments which might be tried, most of which, however, have been tried, and well-tried too, by Mr. George Maw, and other cultivators.

— AN Arboretum was opened the other day at Lincoln. The grounds, which occupy an area of between thirteen and fourteen acres, command a pleasing prospect of the city from the east end, and have hitherto been used as a place of public resort. Since they came into the possession of the Corporation, however, new walks and terraces have been formed, and the whole has undergone extensive alteration and improvement. The close proximity of the park to the town, and the extensive view commanded from its position, must make it one of the most popular resorts of the inhabitants.

"SCIENTIFIC" MEN.

THE following morsel from the *Globe* is a good example of the result of the confused meaning of the word "scientific" that exists in the mind of the public, and too often in that of those who write for it:—"During the former Potato famine, scientific resources [*i.e.*, human knowledge] failed to ameliorate the condition of the crop, and the best means of arresting the disease was to cut the stalk level with the soil. Men of science, at that time, as now, recommended people to plant other vegetables. [This is the course that would probably be followed by most people of intelligence.] We hope ordinary Potato cultivators will not despair, or rely too much upon scientific resources [*i.e.*, on what can be done by man to obviate the disease, we presume.]"

In the above paragraph it is clear that the writer supposes "science" to be something quite different from the knowledge possessed by ordinary mortals.

THE INDOOR GARDEN.

WATER A PLANT CLEANSER.

WE know that water forms the bulk of vegetable matter. But while it feeds it likewise cleanses; and even while doing this latter only, it is rendering the cultivator the highest service. For this end partly, dews are distilled, and the rain is sent down in cleansing showers. They wash leaf, flower, branch, bark, and root; and it is extremely doubtful if, with all our engining and syringing under glass, we wash our plants sufficiently clean. Our heaviest rinsings are but poor substitutes for the hearty downpour of a thunderstorm. What a powerful and thoroughly efficient washing machine is that rent thunder-cloud! and how much of the extraordinary power and energy of vegetable life, noted after it, originates in the efficient and thorough cleansing which it gives to plants! We talk of its having cleared the air, in explanation of its wonderful effects on vegetation; it would be much nearer the truth to say it had cleaned the plants. Let us do likewise under glass, and we may witness similar rapid developments of plant life. Such are by no means unknown. Orange trees, Camellias, vines relieved of their crops, Peaches of their luscious burdens, have been rinsed clean by powerful waterings with the most beneficial results. But to ensure such benefits care is needed to imitate the thunderstorm as closely as we can. Such downpours are mostly soft and warm, and, it may be, surcharged with atmospheric gases. To such qualities chiefly they doubtless owe their sanitary efficiency; while they cleanse they likewise stimulate. On the contrary, our water is too often hard and cold. The result is a check, rather than a help, to growth. We often see this also after a thander shower, when rain like liquid ice or hail falls instead of the warm shower. The plants are battered and bruised rather than cleansed and stimulated. It is often just so with our artificial washings; cold, hard water, charged heavily with lime, is raised often many feet, and dashed against the trembling flowers and shrinking leaves. The results are only evil, as might have been predicated. We must copy nature as closely as possible. Use soft warm water, and charge it slightly with a few knobs of carbonate of ammonia or smelling salts, and then apply it without stint, and we must needs reap the highest sanitary advantages from the artificial thunderstorm. D. T. FISH.

FILMY FERNS.

A LONG list might now be made of these delicate and lovely little plants, which are as well grown and as successfully propagated as any other tribe of Ferns. There are, probably, more than forty species in the fernery at Kew, and scarcely a less number might be found in the nurseries at Foot's Cray, and in those of Messrs. Backhouse, of York; while in almost every other garden of note, a greater or less collection of these pets may now be found. Like everything else, now we know how to manage them, their cultivation seems simple enough, and we wonder how it was that cultivators used to fail with them. Shade and moisture are the two great necessities of their existence; they are absolutely requisite—a gleam of direct sunshine, or a breath of dry air, and the poor little plants would be killed outright. Guard well against these two evils, and all will go well. Soil is a secondary thing with them; they require but very little; the wet surface of a piece of porous stone, or a block of wood, suits them quite as well, or even better. I like best to grow them amongst pieces of sandstone, for though I have several growing well upon the stems of tree Ferns and other vegetable substances, yet

these, with the continued moisture, are apt to rot; they are also likely to produce fungi, both of which circumstances may bring about unpleasant results. A thorough drainage for the pots, and a little fibrous and very sandy peat sprinkled in between the blocks of sandstone, are what experience teaches us to be the best means of growing them. It must be a very snug and quiet corner where they will grow without the protection of a bell-glass; still even this has been accomplished. There is a cavern, deep and shady, with a trickling rill of water in it, in the rockery at Messrs. Backhouse's, where several species grow luxuriantly; but in few gardens can the natural habitat of these plants be so closely imitated. The safest and best plan is to cover them with a bell-glass while young, and as they increase to give them a square hand-glass, the top of which is made moveable. With glasses so made the top can be lifted off without disturbing or injuring the fronds. During summer these plants cannot be kept too moist, if the drainage be good; they may safely be sprinkled with a very fine-rosed watering-pot every morning. They enjoy having their fronds wet. In winter they should be kept a trifle drier, not so much on account of the Ferns, if the air be warm enough, but to guard against mildew. D.

Culture of Melocacti.—In answer to Mr. D. Teasdale's question (see p. 167), as to the best means of preserving and growing his Melocactus, I venture to give an extract from a work which I published a few years since on the culture of Cacti, ("Culture des Cactées," par F. T. Palmer, edited by A. Goin, Paris), in which the numerous plates relating to grafting Cacti explain the different processes respecting that mode of propagation at a glance. "He should take a *Cereus Peruvianus* of about the same diameter as that of the base of his plant, cut off the head of the former, but not so low as to come upon the hard ligneous axis, and then pare off the hard epidermis and ribs for about an inch. He should then take off a fresh slice from the base of his Melocactus, also paring off about an inch of the epidermis all round, and place his plant on the top of the *Cereus*, cut to cut. Then with a doubled string of coarse worsted, tie on the graft firmly, binding the worsted backwards and forwards from the spines of the one to those of the other, but avoiding to cross the apex of his plant, as it might stop its growth. If the weather continue warm enough for about a month longer, the parts will unite before winter, but the ligature had better be left on until the next summer. The precaution of paring off the hard skin and ribs is absolutely necessary, as the juicy centre contracts, and the rind or epidermis does not; there would consequently be a void formed, sufficient to prevent all cohesion, be the graft tied on ever so tightly. His Melocactus will keep very well on a shelf in a dry greenhouse during the winter, and he can graft it the next summer; but an established graft will keep far better, and will start into growth the next spring, thus saving a year and perhaps the plant, as they sometimes rot, even if kept ever so dry. In a hothouse, a grafted Melocactus may be kept in vegetation all the winter."—FRED. PALMER, *Versailles*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Miltonia candida grandiflora.—A fine specimen of this peculiar looking Miltonia is now in flower in Mr. B. S. Williams's collection at Holloway.

Drainage of Pots.—In America in the best nurseries and flower-growing establishments no drainage is used in most of the pots. This applies to *Bouvardias*, *Gardenias*, tree *Carnations*, &c., as well as the softer and commoner bedding-plants.—D.

Oxalis rosea as a Pot Plant.—This delicate and pretty rose-coloured annual is found to be excellent for conservatory decoration grown in pots. The flowers are larger than in the open ground. It has been much used at Kensington this year.

Dendrobium chrysois.—This brilliant-flowered Dendrobe, introduced from Assam in 1870, is now bearing over twenty spikes of golden crimson-blotched flowers at Manley Hall, near Manchester. The striking beauty of the flower is greatly enhanced by the deep fringed margin of the lip. It possesses a vigorous constitution, and grows freely in a moderate temperature.

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM AUGUST 23RD TO SEPTEMBER 4TH, INCLUSIVE.)

BY OUR OWN REPORTERS.

<i>Aplonappus</i>	<i>Colchicum</i>	<i>Podolepis</i>	<i>Tripsacum</i>
<i>Fremontii</i>	<i>crociflorum</i>	<i>affinis</i>	<i>ductyloides</i>
<i>Aster</i>	<i>Inula</i>	<i>Potentilla</i>	<i>Wahlenbergia</i>
<i>bessarabicus</i>	<i>grandiflora</i>	<i>sulphurea</i>	<i>gracilis</i>
<i>leucanthemus</i>	<i>Galatella</i>	<i>Satureja</i>	<i>Valloradia</i>
<i>Bignonia</i>	<i>cana</i>	<i>montana</i>	<i>plumbaginoides</i>
<i>grandiflora</i>	<i>dracunculoides</i>	<i>Stevia</i>	<i>Vernonia</i>
<i>radicans</i>	<i>Mentha</i>	<i>compacta</i>	<i>novaeboracensis</i>
<i>Browallia</i>	<i>Pulegium</i>	<i>Teucrium</i>	<i>Zephyranthes</i>
<i>demissa</i>	<i>Petunia</i>	<i>massiliense</i>	<i>nivea</i>
	<i>nyctaginiflora</i>		

Plants in this list are almost without exception such as have come into bloom during the past week.

THE LARGE FLOWERED MAGNOLIA AT HOME.

BY PETER WALLACE.

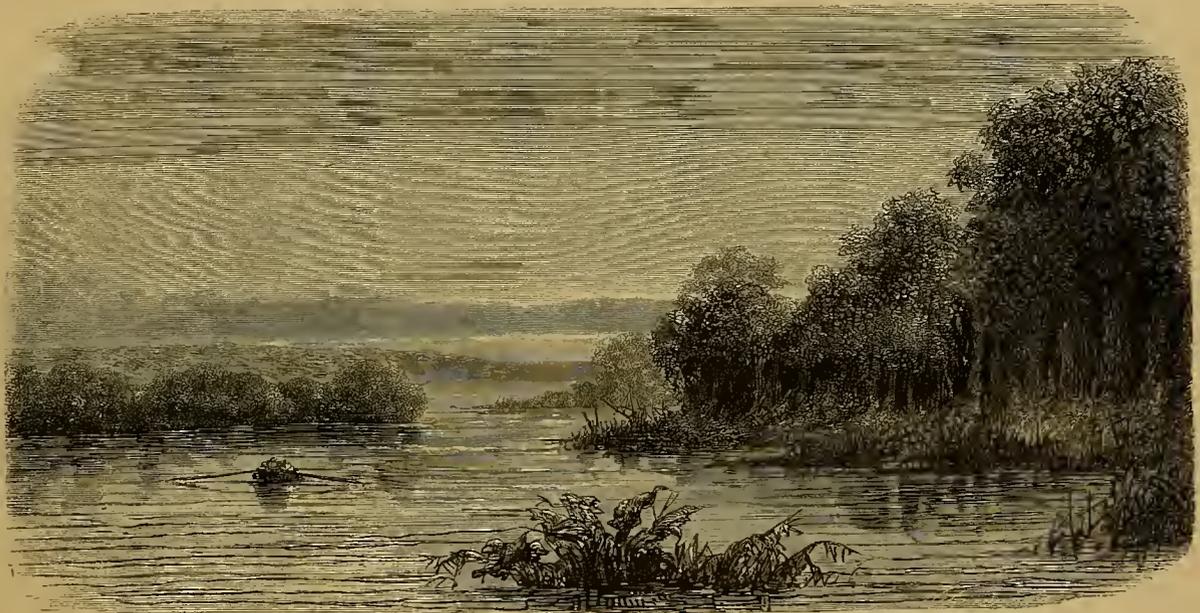

GRAND objects are the Magnolia groves of Louisiana, Southern Texas, and other southern states of America, rising, as they invariably do, on the slopes of the lagoons, bayous, and river banks, and assuming the form of noble forest trees. These Magnolias, individually as well as collectively, are grand, their contour of deep green foliage being bold and majestic, while their large blooms of the purest white fill the air with ambrosial perfume. I am unable, in short, to give in writing anything like an adequate description of these groups of stately trees massed by nature's hands, often in most imposing positions, and in almost every stage of growth, from the thin sapling to giant stems measuring at the base from 6 feet to 9 feet in circumference, and towering from 50 feet to 70 feet in height, affording shade so dense as to defy the sun's rays to penetrate it. To no particular parts of Louisiana, Florida, and Southern Texas are these noble Magnolia trees confined. You come upon them at intervals spread over a wide tract of country, and invariably where the soil is rich and deep, near river banks, by the sluggish waters of the deep bayou, or forming an emerald fringe to the still lagoons, clothing the islets that are scattered among them in

Nature's hand for calm repose, contains some splendid examples of the Magnolias and other fine Texan trees, which I have no doubt will be preserved for centuries to come. Unfortunately, the Magnolia only lives as a standard here and there in the south of England; but it forms a grand plant for high walls.

THE FLOWER GARDEN.

THE CULTURE OF ASTERS.

My beds of broad-petalled Aster, consisting of the following kinds, viz.: three of Pæony Perfection, two of Victoria, and two of Emperor, are now in full beauty; each bed is 40 feet long and 4 feet wide. The Asters are planted in rows, 1 foot from row to row, and 9 inches apart in the row. Of Quilled Asters I have two beds, containing about 400 plants. I do not grow these so extensively; they are exceedingly beautiful, but not so handsome or effective as the others. I prefer planting Asters in beds, and, where possible, in a piece of ground which has been trenched and well-manured in autumn, and exposed to the winter's frost and snow; such is the starting point for success. The beds I have planted with Asters this year were

Magnolia Islands, in Texas.

nature's gayest livery, and affording shelter to the innumerable hosts of duck, teal, and widgeon that frequent the lagoons.

Some of the finest examples of Magnolia grandiflora I saw during my stay in America were on the Buffalo and White Oak bayous, the former being the ship channel from Galveston to Houston. The trees varied from 50 feet to 70 feet in height, having beautiful cone-shaped heads, which in July, 1871, were covered with hundreds of their fine blooms, which the coloured children, with monkey-like activity, managed to secure and carry to the railway stations and elsewhere for sale, and for which they found ready purchasers. Americans have a great love for flowers, and being often unable to spare time from business to cultivate them, they readily pay large sums for cut flowers when they can obtain them. It is to be regretted that the feller's axe spares nothing in its way when opening up a clearing for cotton, sugar, or corn; and annually hundreds of fine examples of Magnolias, as well as other fine trees, are cut down, converted into timber, or burnt. Fortunately for Houston and its neighbourhood, a love for trees and flowers has sprung up, and efforts are being made to preserve some of the best pieces of wood and grove in the vicinity. The new cemetery at Houston, a place shaped by

thoroughly prepared for Hollyhocks last year, and for Dahlias previously, and were in good condition—just in the state I would prescribe. There is a difference between planting and preparing flowers for decorative purposes, and for highly cultivated or exhibition wants. More care, more thought and attention are required for the latter; but how fully is the earnest amateur repaid when he sees in every flower his care and extra attention crowned with success!

Suppose, then, a piece of ground has been secured, and the necessary arrangements made; procure seed from the most reliable source some time during February or March. Half of this I recommend to be sown in the last week of March, in pots or pans; the remaining half to succeed about the 8th or 10th of April. Place on a gentle hotbed, and, as soon as the fourth leaf is produced, transplant carefully into small pots or a warm and sheltered border in due time, not neglecting proper care and attention to the watering, keeping clean, and giving plenty of air when under glass on all favourable occasions. The warm April showers will bring the growing seedlings onwards to the 20th of May. At this time I begin to count up my stock, clean the ground by lightly forking and raking it over, and so prepare for the general planting (which may

be extended till the 16th of June), marking out the beds and paths according to the desired lengths and sizes. If one or more beds are to be planted, take your line and place it up the centre of the bed, and, starting at 6 inches from the end, at intervals of 1 foot, make with a fair-sized dibbler a hole 6 inches deep. On either side of this line make two other lines about 9 inches apart, with holes in a line across the bed. You can then tell precisely the number of plants required. It is my custom to raise separately each colour and sort of Asters, &c., and plant them out, so that the colours contrast; for instance, one or two rows of blue, then white, then red, and so on. Having made the holes, fill up each with water, and allow it to sink before a plant is inserted; then carefully place each plant in its hole; surround it firmly with the earth, never allowing a vacuum to exist between the roots and the soil. Choose, if you can, the time just previous to a good downpour, otherwise, having planted, it is well to give a surface watering to each plant. I have not given a drop of water since planting this season. I well recollect in my school-days a good and worthy old gardener spicing my labours with this good advice (it was a simple lesson, but none the less important; I applied it from his lips and do yet adhere to the plain common-sense teaching, which will not prove a failure in its results): "My boy," said he, "put that water in the hole first and give the plant time to find it; it is better than allowing the water to find the plant." I have proved the good effect of his advice in transplanting trees and shrubs. Just as the Asters show bloom, carefully go over them and remove part of the flower-buds, and, whilst I do not put my faith in the antiquated, worn-out, and tattered garment of "garden secrets," let me advise how many, which, and what to leave, for on this greatly depend the beauty, size, and full development of flower and seed. I usually leave three flowers, the centre and two top terminals, and all the foliage possible. To digress for a minute, if any one wishes to perpetuate a good strain or variety of Stock or Wallflower, and produce doubleness, let him select a good habited simple flower, cut off the flowers from the laterals, and allow only the main or central spike to bloom, which should be reduced, before its seed-vessels are formed, to three, six, eight, or twelve blooms, according to the vigour and energy of the plant. I find on this principle that, if the weather will permit, I can, with certainty, produce better home-grown Asters than from imported seed. The difference is great when one sees them side by side. Having thus far proceeded in thinning, let a top-dressing of well-decomposed strong manure be placed over the beds, and, if the soil is comparatively cold or wet, a sprinkling of about an egg-cupful of guano round each plant, just midway, or two or three sprinklings of soot during the season will benefit them, although not always necessary. I also attach a stake to my plants, and loop the flowers to it in case of heavy wet or wind, so as to secure them. By planting-out a few days later those sown last, the season of blooming is prolonged. Owing to the wet and comparatively hot season we have had, my Asters are forward; the fact is, they have made an uninterrupted growth and are now in full beauty, the central blooms being open, while the lateral ones are more or less backward. The last and not least requirement is to secure good seed; we have only to mark any worthy or beautiful and distinct variety, take it up if the weather is not likely to allow of its maturation of seed outside, pot it, and keep it under glass until it has ripened its seed.

JABEZ J. CHATER.

Gonville Nurseries, Cambridge.

Chrysanthemum carinatum.—Amongst hardy annuals growing from eighteen inches to two feet high, it would be difficult to find anything more noble or showy than this plant and its almost numberless varieties. It is, perhaps, better known as the Tricolour Chrysanthemum, from the three colours that exist in one of the best known forms of it. Much attention has been bestowed upon the different varieties of this annual by Messrs. Carter & Co. at their seed farms; and by saving seed from the largest flowers and the most distinctly marked colours, some beautiful strains of it have been obtained. Long strips of land stretching across one of their farms, planted with these Chrysanthemums, presented a fine effect during the first week in August. The white, the double white, and the double quilled white, with similar differences in the yellow varie-

ties, were associated with several different variations in the tri-colours, many of which had blooms three inches in diameter. The profuse way in which this Chrysanthemum flowers, and the purity of its various colours, combine to render it one of the best annuals we have for clumps, amongst and in front of shrubs, and for telling effect in large bedding arrangements.—W. T.

THE GREAT WATER-DOCK.

(RUMEX HYDROLAPATHUM).

THE lamentably bare and monotonous aspect which the margins of pieces of artificial water too often present, might be very wisely, cheaply, and effectively relieved by the introduction of a few of our larger native aquatic plants, such as the Typhas, taller Carices, Sparganium, Arundo Phragmites, Iris Pseud-acorus, and the subject of our present notice. The great Water-Dock is common in most parts of Britain in wet ditches and by the edges of streams and pools of standing water, growing to a height of from three to five feet, and forming a huge pyramidal mass of immense leaves. During the summer they continue of a dark green colour, but at the approach of autumn change to a deep lurid red hue, which they preserve for a considerable time, mingling their tints not inharmoniously with the various shades of brown and yellow foliage which mark the decline of the year. It is at this period perhaps that the plant is most striking in appearance, but it is at all times a bold and effective object, suggesting more than

The Great Water-Dock. (After Smee.)

any other British plant the development of vegetable growth which characterizes the flora of sub-tropical climes. We call the attention of our readers to this plant as one that will well repay the trifling trouble of procuring and planting it. A root or two deposited in the mud near the bank of a pond or slow stream will require no further attention.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Mesembryanthemum cordifolium variegatum.—This, I find, is one of my best variegated plants in a large collection. It is admirably suited for bedding, and does not suffer in the least from cold or heavy rains.—W. FAIRBAIRN.

Ornamental Grasses.—These are by no means sufficiently known or grown. One of the most graceful of them now in flower is *Piptatherum multiflorum*, a plant which is about a yard high, and which produces elegant airy panicles in profusion. A specimen of it may be now seen in the herbaceous ground at Kew.

Double Portulacas.—These charming little flowers, which look like miniature double Roses, are excellent for various purposes in the flower garden, as for example for planting here and there on the bare parts of the rock garden, as carpeting plants beneath taller subjects, and as edgings to small mixed beds.—LOUISA M.

Roses.—I have a Rose garden which produces very fine Roses in the summer, but after the first bloom most of my plants drop their leaves, or, if not, the leaves are covered with black spots, and have a burnt, shrivelled, unhealthy appearance. I gave them a good coat of manure in the winter, and forked it in in the spring, as directed in Mr. Hole's book. As to watering, we have had plenty of rain, besides which I gave them manure-water.—ROGER. [Defective drainage or the want of a free circulation of air will produce the effects of which you complain. If soil and situation are right, give less artificial moisture to the roots next season; and I would recommend you now to syringe your trees with tobacco-water, or to wash them with soap and water.—S. R. H.]

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 196.)

RAISING PLANTS FROM SPORES.

SPORES are the germ-cells of Cryptogamous plants. Of these only the higher groups of Ferns, Lycopods, and Rhizocarps have, up to the present, been cultivated in our plant-houses and rooms. In rooms, hardly any other kinds than Ferns are raised from spores, and the following remarks are therefore more particularly applicable to them. The spores of Ferns should be sown in pans in coarse fibrous heath soil, with which the pan is filled up to within a quarter of an inch from the rim, in the same way as has been recommended for the sowing of the smaller kinds of seeds; or pieces of close fibrous peat soil may be used. In both cases the soil is kept moist entirely from the saucer in which the pan is placed, or in which the pieces of peat soil have been laid. It is also to be recommended that the heath or peat soil should be previously submitted to a heat of from 170° to 212° Fahr., in order to destroy any seeds of weeds, eggs of insects, worms, &c., which it may contain. Spores taken from Ferns which have lain in a herbarium for ten, and in some cases for fifteen and twenty years, have germinated and produced fine plants. The late Herr Plaschnik, curator of the Leipzig Botanical Gardens, one of the earliest and most successful of German Fern growers, was one of the first to introduce into cultivation a number of species of Ferns which he raised from spores taken from herbariums. The proper time for gathering Fern spores for sowing is when the membranous spore-covers on the underside of the frond have become of a ripe brown colour. Parts of the frond should not be chosen on which these spore-covers have already burst and discharged their spores, as in this case only spore-covers without spores would be sown, and no result would follow. The inexperienced amateur might very easily mistake these small spore-covers for the spores themselves, and so make the same mistake in sowing them as if he were to sow the empty shells or pods of seeds of phanerogamous plants. He should therefore assist his eyes with a magnifying glass in examining the condition of the spores which he intends to sow. This will show him the spores in a very fine powder, and the little sac-like spore-covers, when thus magnified, will be readily distinguished. In the case of Fern-fronds kept in a herbarium, or lapped up in paper, the spores will generally be found to have fallen out of the spore-covers, and adhering to the surface of the frond or to the paper, while the spore-covers or receptacles will, in the greater number of cases, be quite empty.

When spores are taken from the growing plant for sowing, portions of the fruit-bearing fronds should be cut off when the spore-covers begin to assume a brownish hue. These should be placed in a closed packet of smooth paper, and laid in a dry place for some days. When it is required to sow them, the paper packet should be carefully opened and spread out, so that none of the spores which have fallen out of their receptacles may be scattered. The spore-covers with their spores should then be carefully scraped from the frond with a knife into the paper. A pan having been previously prepared with suitable soil, the latter should be moistened and the spores carefully shaken out of the paper upon it. These remarks are also applicable to spores taken from a herbarium. Even with very great care, it will sometimes happen that some of the spores will be scattered and carried by the wind to other pots or pans which stand prepared for other kinds to be sown in them, so that unless special attention is given, the cultivator may see various kinds springing up together in the same seed-pan. He will therefore do well, when sowing Fern-spores, to see that no other prepared pots, or Ferns with ripe spores, stand near. He should also sow each kind by itself, and then carry the pan to its place, wiping his hands well with a cloth before he commences the sowing of the next kind. When the spores are sown in a pan filled with heath-soil, the pan should be covered with a sheet of glass and placed in a shady part of a warm room, where even species from cool climates will germinate much better than in a cool position. The soil is to be kept

moist by pouring water into the saucer. Spores sown on pieces of fibrous peat should be covered with a bell-glass, or placed in a warm box or in the terrarium and kept moist in the same manner. The seed-pan may also be placed inside of a larger pan or a wooden box, and moss placed round it up to the rim. This moss being kept constantly moist, and the pan being covered with a bell-glass or a sheet of glass, an agreeable degree of moisture will be produced and all dangerous extremes will be avoided. From this time forward the seed-pans should be examined every day, and the condensed moisture wiped off from the inside of the bell-glass or sheet of glass from time to time. When a greenish tinge comes over the surface of the soil, it is a sign that the spores have begun to germinate. From this time forward the greatest care and attention are necessary, especially with the rarer kinds. The pans should now be placed in a better lighted, but yet shady position, every excess of moisture must be carefully guarded against, and the glass covering or bell-glass should be slightly ventilated, so that a circulation of fresh air may be always maintained. The condensed moisture should also be so often wiped off the glass that it will never drop on the young plants, as it would prove fatal to them. As soon as a few leaflets are formed, the seedlings should be transplanted, either several together in large pans, or single plants in small pots filled with heath-soil, and covered with a bell-glass or placed in a glazed case.—*Dr. Regel.*

ORCHID FLOWERS FOR TABLE-DECORATION.

It is instructive to note the progress made of late in the art of table-decoration. It appears quite an enormous leap from the mass of rich plate and gorgeous heavy bouquets that used to decorate the tables of the rich, to a style of the greatest possible simplicity, elegance, and grace. I do not condemn simplicity, for it is certainly a decided improvement; but to the use of hardy flowers alone, when tender ones can be had, I quite object. There are few ladies, who, however cultivated their taste, would not prefer an elegantly arranged table, gracefully decorated with sprays of various of our "bridal" orchids, mingled with other suitable relieving subjects, whether tender or hardy, to one composed solely of Harebells, Forget-me-nots, white Water Lilies, Veronicas, and grasses. The tables lately exhibited by Miss Hassard, Miss Blair, and others, sufficiently attest what can be done with hardy and greenhouse flowers; but at all the late exhibitions scarcely was there an instance where the blooms of Orchids and other tender plants were used to advantage. Those who might have successfully done it, no doubt abandoned the thought, when they beheld the tide of success flowing towards the simpler compositions. This, however, should not be so; for although hardy flowers are mostly within the reach of all, those who have, or can afford to obtain, the rich, waxy, and enchanting flowers of some of our Dendrobiums, Odontoglossums, Oncidiums, Phalenopsis, and many others, by an elaborate system of arrangement, can, in union with other suitable flowers, Fern-fronds, and Grasses, produce a style of table-decoration unequalled by the most elegant composition of hardy flowers alone. If the tables are only required for one night's use many flowers could be used that could not if they were required to stand for several nights; as, for instance, our *Aërides*, *Saccolabiums*, and some Dendrobiums, that would be of little service otherwise than wired, could be effectively employed; these may sometimes be advantageously used without wires, but, although graceful in the extreme when growing on the plants, they are too apt to assume a clumsy appearance if used for furnishing table vases unless wired, and if they are so done they cannot get moisture to sustain their blooms in that desirable plump condition they would retain should their stalks be inserted in water, damp sand, &c. Again, Orchid flowers are more capable, after being cut, of maintaining their freshness and colour for a considerable time, if placed in water, than those of most other plants.

Grass as an accompanying or relieving subject is good enough in its place; indeed, its presence is hardly dispensable; still its too lavish use is too often indulged in. We have now various forms of graceful ferns amongst our Pterises, Adiantums, Cheilanthes, Pellæas, &c., that would add nobly to the cause had they only a chance. At the Crystal Palace Great Rose Show this summer I noticed one table so furnished with the fronds of the beautiful Adiantum Farleyense as to make it quite objectionable, for although this is one of the most beautiful of ferns, its fronds are too closely covered with pinnæ to be of great service in this branch; small bits occasionally used may be of some consequence, but its whole character is too heavy to use much of it.

WM. FALCONER.

VASES OF FLOWERS.

WHAT horrid things some of the florists do give us in the way of bouquets! They pack the dear little flowers so closely together, such crowds of sweet faces massed, that you cannot half enjoy any of them. I should think that any one who really loves a flower would do it better justice. Each fine blossom or cluster of blossoms ought to have some quiet background to set it forth. Green foliage, in delicate sprays or handsome leaves, is according to nature's general plan. I remember the exquisite little floral ornaments in that pleasant sitting-room of B.'s. Shells of various kinds were made to do duty as vases; here a few Geranium leaves, with Rosebuds or Pansies in a shell turned up so as to hold water enough to preserve the flowers, and there a cluster of Sweet-pea blossoms, with foliage of some light graceful character. One handsome Lily, with leaves, is often quite enough for a flower-vase. I was not more than half a score of years old when I saw two vases of flowers on a mantel-piece which pleased me better than anything I had ever seen before, and their memory is still pleasing through all the years since that time. The vases were tall old-fashioned wine-glasses, and the flowers were only Nasturtiums, a spray in each, with their brilliant flowers, odd-looking leaves, and smooth curling stems. We want some large wide-mouthed vases and some big bouquets when flowers are plentiful. Some large vases we must have for the children to fill. Some flowers have such short stems that they cannot be managed in bouquets unless they are furnished with artificial stems of wire or straw. Hollyhocks and Balsams are of this kind. The best way to arrange these is in a plate of clean wet sand. Use plenty of Ferns or green leaves with the flowers.

R. L. F.

Plant Screens in Rooms.—To have living screens in drawing-rooms and saloons is a favourite practice at Trentham, Cliveden, and other large houses, and they might advantageously be introduced generally. Upright trellises, covered with the ivy green or any other suitable climber, and springing from oblong boxes, the soil being placed in narrow troughs, which are placed within ornamental ones of various materials and patterns, so that a particle of moisture cannot descend on the floor, and the whole so arranged that they can be conveniently moved to any part of the room where a screen may be desired, are elegant and useful ornaments in large drawing-rooms and saloons. Of course these screens are more suitable to very large rooms than to those of ordinary size. In large saloons and drawing-rooms, where a person reading or writing may desire to be cut off from the general glare or openness of the apartment, they are particularly useful. They are generally made of ivy, but at Trentham they are beautifully covered with the common annual *Thunbergias*, orange and white with dark eyes, and several other slight varieties. These are the common annual *Thunbergias*, which are sold at a few pence per packet. They are stove plants, or nearly so, and therefore only suited to the wants of those with plant-houses. Of course those on the trellises were grown in a warm moist house, and then removed to the mansion when coming into flower. The Ivy screen may be formed without the aid of glass. The best way would be to get a number of young fresh plants, with stems beginning to grow freely, train the stems to the wires of the erect trellis, and leave them in the air in some favourable spot where they might get established previous to being taken indoors. The Irish Ivy is the best variety.

R.

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

Asplenium flagelliforme.—This is the most beautiful of all ferns for growing in the sitting-room. A plant of it in a suspended basket for the past two years is now the admiration of all who see it. The drooping fronds hang down most gracefully, each terminated by the long wire-like midrib, which is prolonged beyond the pinnæ in such a singular manner.

Window Boxes.—Our ordinary London Mignonette boxes have given place, of late years, to fine majolica troughs, overflowing with the most brilliant blossoms. But when we find the glaring colours of majolica associated with brilliant blossoms, it becomes difficult to fully and efficiently condemn the bad taste which groups many-coloured flowering plants in many-coloured receptacles.—W. T. P.

Pomponé Dahlias.—I find these pretty bachelor's-button-like Dahlias among my most useful flowers for cutting. The flowers are not one-fourth the size of the older kinds, and have a neatness and absence of coarseness about them, that makes them very attractive. My most favourite kind is one called German Daisy, which varies agreeably in colour, but there are various others quite as attractive.—Louise.

Creeping Jenny.—This native plant is now much used in London. In window boxes, drooping over their edges, and flowering freely, or grown in pots, or suspended over the area with its long shoots drooping down so as to cover the pot, and fall gracefully for nearly a yard below, it forms the most graceful and attractive plant now to be seen. It seems, above all plants, to have no objection to growing down into dark places. We sometimes see it planted on the edge of the narrow trench-like areas of the small suburban gardens, falling down into them, and perfectly clothing the wall with graceful shoots and yellow blossoms.

HORTICULTURE AS A PROFESSION FOR LADIES.

AN able suggestion regarding a new profession for gentlemen was made a short time since. Why, said the *Pall Mall Gazette*, should not Horticultural pursuits be erected into a "gentlemanly profession?" "Why not, indeed?" echoes a correspondent of the *Queen*. "And why not also, I beg leave to add, into a ladylike profession? I throw out the suggestion as affording a new and perfectly legitimate opening for the employment of women, and in a field in which numbers of ladies excel? Why should we not have our female Paxtons and Kents? Mrs. Loudon, instructed no doubt by her talented husband, imbibed a great taste for and love of the art; and other ladies might find in horticulture a profession which would be remunerative, and could not detract in itself in any way from their social status as gentlewomen. Leaving the laying out of landscape gardens and parks to the gentlemen, there is still, in other branches, a wide field open, in which ladies thoroughly educated in horticulture and botany might find employment, and in which their less fortunate sisters, with ordinary strength and less preliminary training, might work. I remember, a short time since, reading an account of a college or school of horticulture for women in America, and it has long been matter of astonishment to me that, in the present dearth of remunerative employment for women of the middle class, no one has as yet thought of making them 'gardeners.' I remember that one of my sisters and myself, in utter despair of getting any good work or good result in the way of flowers for effect or fruit for eating, from our coachman-gardener, took upon ourselves the superintendence of the greenhouse and outdoor garden. The former was a very large one, the latter a good-sized but pretty suburban piece of ground. We only stipulated for the services of our man to remove large pots, dig the ground (where very heavy), and wash the greenhouse. We went to work with enthusiasm, determined to succeed, and we did succeed of course; women afraid of soiling their hands or spoiling their complexion I do not address. My suggestions are meant for those who look upon the duties of life seriously, and who, being compelled by circumstances to earn their daily subsistence, would find in horticulture not only a remunerative but delightful occupation; and if the *Pall Mall* correspondent be correct in his views, it would pay. 'I,' for my part, he says, 'and I have heard others say the same, would often be glad to pay my guinea for a visit from a skilled horticulturist.' If the want of knowledge among gardeners is as great as this implies, women, by taking up the profession, could do no injury to the other sex; they could oust no one from his place, and would simply step into a void, filling up the gap between the shining lights of horticulture and botany and the obstinate jobbing gardener, who very often takes the name of one without any knowledge of the duties, but a great idea of the perquisites, of the situation."

THE FORGET-ME-NOT.

THERE is a little and a pretty flower,
That you may find in many a garden plot;
Yet wild it is, and grows amid the stour
Of public roads, as in close-wattled bower:
Its name in English is Forget-me-not.

Sweet was the fancy of those antique ages
That put a heart in every stirring leaf,
Writing deep morals upon Nature's pages,
Turning sweet flowers into deathless sages,
To calm our joy and sanctify our grief.

And gladly would I know the man or child;—
But no! it surely was a pensive girl
That gave so sweet a name to floweret wild,
A harmless innocent, and unbeguiled,
To whom a flower is precious as a pearl.

Fain would I know, and yet I can but guess,
How the blue floweret won a name so sweet.
Did some fond mother, bending down to bless
Her sailing son with last and fond caress,
Give the small plant to guard him through the fleet?

Did a kind maid, that thought her lover all
By which a maid would fain beloved be,
Leaning against a ruin'd abbey wall,
Make of the flower an am'rous coronal,
That still should breathe and whisper, "Think of me"?

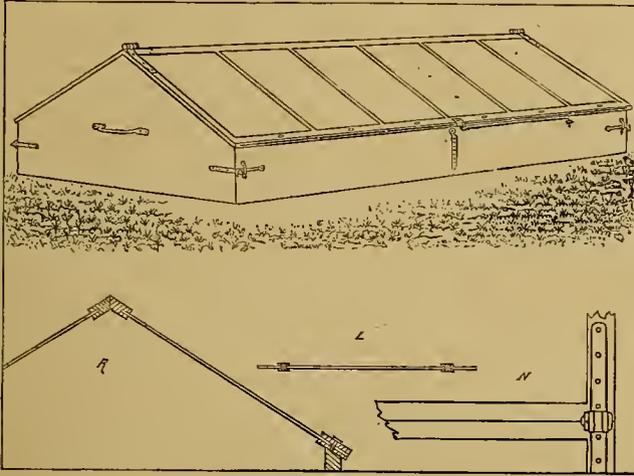

But were I good and holy as a saint,
Or hermit dweller in secluded grot,
If e'er the soul in hope and love were faint,
Then, like an antidote to mortal taint,
I'd give the pretty flower Forget-me-not.

Hartley Coleridge.

GARDEN STRUCTURES.

LLOYD'S GROUND VINERY.

AMONG the various ground vineries shown at Birmingham, one of the best was that shown by Mr. Lloyd of Grantham, of which we give a figure and details, from sketches by our special artist at the Birmingham show. Our engraving represents one fixed together six feet long. They are made from two to six feet wide, and when separated form eight parts. Two wrought iron tie girders, bent as in section fig. R, form the frame, to which are bolted two boarded sides; the loose wood ends, being grooved and tongued together, shut against the iron girders, and are secured by iron hook hasps at the corners. The roof is constructed with patent sashes having grooved bars, and the glass is slid into position, as shown in fig. L; the front edge has a moveable fillet, which, when screwed down, protects and secures

Lloyd's Ground Vinery.

the glass, and allows rain water to run off. Damages in the glass may readily be repaired without sending for a glazier. The sashes are hung with wrought iron rule joints, as shown in fig. N; they are bolted at the angle of the iron girders, and allow the sashes to be turned over and to rest upon each other; a hook and eye are provided to set the sashes at any angle for ventilation and convenience in glazing. These Vineries are easily fixed together or taken to pieces, and, when required, the lengths may be hooked together so as to form rows of twelve, eighteen feet, or more, and when packed for transit occupy a small space. These miniature structures are useful in garden operations for a variety of purposes, viz.:—For wintering Auriculas, Carnations, Primulas, Calceolarias, potted Strawberries, Cauliflowers, Lettuce, growing and hardening off bedding plants, raising delicate seeds, or for Cucumber growing, as well as that of Vines.

United Order of Free Gardeners.—The United Order of Free Gardeners, which seems of late to be making very rapid progress in Shrewsbury, is, says a correspondent, a friendly society, concerning which some little misconception prevails in certain quarters. Its name would lead to the supposition that it was a society formed for practical gardeners alone; but it only needs the slightest acquaintance with the Order and its principles to see that they are intended for universal application. The Order of Ancient Free Gardeners, which has at any rate the merit of antiquity, dating its origin so far back as the thirteenth century, was merged into the United Order of Free Gardeners a little over a quarter of a century ago. The title "Gardener" signifies that the Order originated among a few toilers of the craft, who banded together for their mutual benefit. The idea of unity was a good one. This brotherly feeling having sprung up among them the ties at length became stronger, and the brethren more numerous, until they formed themselves into lodges, and ultimately into a secret Order. They were governed by officers duly appointed, and a law of the society, which dates thirty years back, provided that any person who joined the society must be a practical gardener. Hence the notion which now prevails that it is intended for such persons alone. This law was, however, eventually cast aside, and persons of all ranks became eligible for admission.

GARDENING IN THE SOUTH OF IRELAND.

BY NOEL HUMPHREYS.

PASSING the noble belt of wood that skirts the domain of Mr. Townsend, of Derry, as that picturesque property is called, I was struck with the fine growth of some American Oaks and Spanish Chestnuts, and also with some fine Conifers, of species unusual in this part of the country; in fact, the whole belt of shrubs and trees I am alluding to looked so thriving and handsome, that, when I arrived at the lodge, I enquired if a stranger might be permitted to see the interior plantations and gardens. My request being acceded to, I at once entered. The lodge is a pretty modern structure, in the Swiss-Gothic style, as it is called, and it is covered with Fuchsias and climbing Roses, which make it quite a picture; but, after the fashion of this part of the country, no attempt has been made to surround the lodge with a pretty flower garden, as is almost invariably the case at the entrance of an English domain, of however small extent.

The Rhododendrons and Aucubas form conspicuous objects on either side of the drive, from their great size, and their luxuriant growth; but I did not observe any of the new varieties of the Aucuba, though the female plant, with its large red berries, would make such a fine object here in autumn and winter. The Rhododendrons were apparently all of the old ponticum breed, which is to be regretted, for doubtless all the tenderer kinds would do well. The view from the front of the house (which is of the old Irish manor-house type, rough cast and yellow-washed) is decidedly fine. It extends over the waters of Ross barbour, and the ocean beyond, and the foreground, formed by the grounds, is sufficiently good. But there are two or three trees requiring obliteration, in order to open up and improve the picture. They are not remarkable either for size or growth, but yet they would, as I learnt, be felled with much regret, and naturally so, as timber is the one thing most wanted about Irish country-houses and Irish scenery in general.

In front of the house is a small geometrical flower garden, not at all equal to the situation. It wants both length and breadth, but the young gardener, Mr. Clarke, whose father has the care of the noble collection of plants at Lakelands, near Cork, is doing his best to make the place attractive for the reception of the family, expected shortly from the Continent. Mr. Clarke has introduced a few features in the bedding system which may be worth attention, as, for instance, forming some of his masses of purple by means of the hardy Verbena, *V. venosa*, which will stand even English winters if not very severe, and make gay patches of bright colour early in summer, long before the tenderer species, which are always checked for a while by removal from their places of shelter in frame or greenhouse. As a dark edging, he makes use of the deep puce-leaved Waterloo Beet, which, being naturally dwarf, requires no pinching, pegging down, or trimming. The Geraniums did not appear to be doing so well as with us, but bedding Calceolarias, both yellow and brown, which have been a partial failure this season in England, were answering extremely well, and even growing luxuriantly here. If this front flower garden were considerably extended on both sides, and a portico and low terrace of suitable style added to the old-fashioned residence, the front of Derry House might be made remarkably beautiful, nature having already done so much. These improvements may, however, be already projected; among the many which I noticed in progress, new walks are planned throughout what we should call the park, but which is here termed the lawn—many Irish lawns extending to forty or fifty acres. Most of these improvements are in a more or less forward state; I am speaking of the "lawn" and shrubberies, and not of the handsome quadrangle of new stabling which is nearly completed.

I was next taken to a new vinery, which promises well, the young plants making way strongly, and a few old ones having been got into such good order since last year that they are showing remarkably fine crops; especially two Black Hamburgh plants and a Muscat of Alexandria. The vegetable garden is also being improved, and is a real conquest over rank, ragged, rocky nature; every inch of ground, as frequently happens in this mountainous part of the country, having to be torn from the dominion of the rocks. If one wanted a rockery, rich in Ferns and Stonecrops, creeping Hypericums and purple Heaths of every shade, nature has done it here ready to one's hand, without a single interfering touch of art being necessary; but Cabbages, Broccoli, Asparagus, French Beans, &c., require human aid against the tyranny of the rocks, and war has to be declared, backed by plenty of gunpowder for blasting purposes, before these stony-hearted enemies of Brassica oleracea and its congeners can be driven from their strongholds. When that is once done, however, a good garden is pretty nearly certain, for the *débris* forms a very prolific soil.

There is a detached walled flower garden among the woods here, which is quite a dainty retreat, snug and retired, and disturbed by no sound but the song of birds. A rustic bench under the trees

which droop over the north wall makes a charming "lovers' seat"—no doubt soft nothings have often been whispered there—and often will be again, and the tale told that, old as it is, and hackneyed, never loses its attraction—"the old, old story." In the centre of this pretty garden in the woods is a handsome new greenhouse, in which is quite a splendid show of plants. Among these I noticed the fine double scarlet *Geranium Victor*, and the giant-flowered single ones *Warrior* and *Leonidas*, some exquisitely grown specimens of the pretty variegated ivy-leaved *L'Élegante*, and a great hush of *Eugene Buengoch*, with its profuse masses of blush-toned flowers; while outside was a fine collection of *Gladioli* in full bloom. Altogether my morning visit to Mr. Townsend's place at Derry was a very agreeable one.

THE KITCHEN GARDEN.

AN ASPARAGUS-GROWING COMPANY.

THANKS to favourable conditions of soil and climate, as well as to careful cultivation, the country round Brunswick is acquiring a reputation for Asparagus which bids fair to rival that of Argenteuil in France. Whilst a few years ago the production of that wholesome and much-esteemed vegetable was confined to market-gardeners and men of some means, and the quantity raised merely sufficed to satisfy the wants of the neighbouring town, the area now devoted to its growth is several hundreds of acres in extent, and so great is the demand for it—both in the fresh and preserved state—in the populous centres of Northern Germany, that its cultivation is largely engaging the farmers and even landed proprietors. With the threefold object of increasing the production, keeping up the price and reputation of Brunswick Asparagus, by regulating the supply and placing growers in a more independent position with the different classes of purchasers, greengrocers, provision merchants, &c., some of the principal cultivators formed themselves in 1869 into an Asparagus-growing company, and, as the movement has been attended with highly satisfactory results, it may not be uninteresting to glance at a few of its more characteristic features.

CONDITIONS.

The capital of the company is fixed provisionally at 3000 thalers (£450), to be raised by the issue of shares of 25 thalers (£3 15s.) each. By a vote of the majority at a general meeting it may be increased to 20,000 thalers (£3,000). Only those persons are entitled to become shareholders and members of the association who live within a certain radius of the town of Brunswick, and have in their occupation land suited for raising the best quality of Asparagus. Applications respecting membership must be addressed to the council or board of directors. The latter decides as well on the claims of candidates for admission as on the price at which, on the death of a shareholder, his shares shall be bought in by the company or transferred to another applicant. For each share a member possesses he is under the obligation to deliver during the season, at the company's stores, 150 lbs. of Asparagus grown by himself. He must deliver up to the 18th of May 28 lbs. a week, and after that day 25 lbs. The board is, however, empowered to modify these conditions whenever circumstances may render it desirable. Two-thirds of the Asparagus delivered must be of the best quality, the managing director to decide whether the goods come up to the required standard. Should his decision be called in question by a shareholder, the latter has the right of appeal to the board. The price which members are to be paid for their produce depends upon the favourableness or unfavourableness of the season, and other circumstances, and is fixed periodically by the board. It is the board, also, which decides what shall be the selling price of the vegetable. Any member not fulfilling his obligations towards the company respecting the quality or quantity of the Asparagus, or the time of delivery, is fined three groschen (3½d.) for every pound rejected or deficient, and must submit besides to a proportional diminution of his share of the annual profits. The board is authorised to purchase Asparagus from non-members, provided their goods are equal in quality to what is supplied by members, and not paid for at a higher price. When, however, no advantage is gained by dealing with "outsiders," and the demand can be satisfied by members of the association, the preference must always be given to the latter. As fast as the deliveries take place, they are of course entered in the company's books in the names of the respective growers, and a settlement takes place at the close of each week. The financial year extends from the 1st of January of one year to the 31st January of the next, and during eight days the annual balance-sheet lies open for the inspection of shareholders. What dividend shall be declared, or how the profits are to be applied, is decided at the general meeting convened to receive the yearly

statements. The director and staff are placed under the control of the council or managing board appointed by the shareholders. The members of this board, who are entrusted, of course, with the arrangement of all important details connected with the working and organization of the undertaking, receive no remuneration for their services.

COST AND YIELD.

With regard to the yield per acre of Asparagus, it varies with the soil, climate, situation, mode of culture, &c., from 300 lbs., or, in unfavourable years, still less, up to 1250 lbs. According to its quality, the produce is divided into prima, secunda, and "soup" Asparagus, the first being worth, on an average, 1s. to 1s. 2d., the second 6d. to 8½d. and the third 3d. to 4d. per lb. Last year—considered rather a poor one for growers—the company sold 40,000 lbs. of prime quality, the produce of 125 acres, at 1s. per lb. It thus realised, without taking secunda and soup Asparagus into account, over £16 per acre. According to Mr. Struck, the company's manager, the expenditure (wages, manure bills, &c.), connected with the preparation of land for Asparagus culture, together with the rent and sum put aside as a reserve fund, represent a capital, or first outlay, of £50 to £70 per acre. The reserve fund is intended to cover the loss otherwise entailed on the grower by the non-productiveness of the soil during the first three years, and by its probable exhaustion or unfitness for further cropping with Asparagus, on a large scale, at the end of ten years. Although the first outlay in raising Asparagus is somewhat considerable, the cost of cultivation, &c., per acre, if the average of several years be taken, does not, it is estimated, exceed £25; and, as the gross return amounts to between £35 and £50, in exceptionally favourable years reaching even to £120, the margin for profit is sufficiently ample. Thanks to direct railway communication and a well-organized system of transit, Asparagus gathered in the neighbourhood of Brunswick at sunrise can be delivered in Hamburg, Bremen, Hanover, Magdeburg, and Leipzig in time for early dinner. The price of the vegetable in Berlin and other places formerly fluctuated very much, and was liable, owing to the rapid growth of the crop in favourable weather and the consequent overstocking of the market, to great and sudden depression. The supply is, however, now better regulated. That portion of the produce intended to be sent off in a fresh state must, according to the company's rules, be six inches to seven inches in length, white, and, of course, newly gathered, and free from all damage. It is packed in baskets specially made for the purpose, and which are mostly large enough to hold 100 lbs. The Asparagus not destined for immediate consumption is preserved in tins, for use when fresh Asparagus is not to be had.

SOIL AND PLANTING.

As to the soil considered most favourable for Asparagus culture, a deep and tolerably retentive sandy loam is the one preferred. Neither too great moisture, nor on the other hand over-dryness, suits the plant. Land well adapted for its growth commands a rent of £5 to £7 per acre. The first operation—and it is performed in the autumn—is to mark out the ground into beds 2½ feet to 3 feet wide, and then to cover the latter with soil taken from the intervening alleys. When the beds have been raked smooth, the next step is to put on them a good dressing of moderately well-rotted stable manure, and to spread some of the rich soil over the dung. Upon beds so formed it is usual with some growers to pour liquid manure. Land of a stiffer, naturally more tenacious character can only be rendered fit for Asparagus culture by an admixture with lighter soil, and the cultivator has then to proceed quite differently in the preparation of his beds. It is, however, only in gardens that the vegetable is grown on heavy land, and we are here concerned only with its culture as a field crop. The season for planting is the spring, and it is usual to put in the young plants in two rows, 1½ foot to 2 feet apart in the row. The roots of the plant are carefully spread over the soil, which has been placed ready in little heaps, and they are then covered in with well-manured earth, taken from a basket at the planter's side. As soon as the planting is completed, some more rich soil is put on the beds, until it forms a layer above the roots of about 2 inches to 3 inches deep. Although Asparagus is an indigenous plant, and grows wild on the sandy shores of the sea and in other favourable localities in different parts of Europe, when raised on a large scale it is only by means of careful, laborious cultivation that continuous good crops of the vegetable can be obtained. Much depends, of course, on the seed and on the judicious selection of the young plants, and, knowing this, the Brunswick cultivator raises his supply of plants from seed of his own growing. He chooses for sowing medium-sized grains taken from the thicker, tenderer (more delicate) specimens which are not overlaid with seed, and for the plantation he confines himself to vigorous well-rooted plants. As soon as the young plants have reached such a size as to render them liable, if unsupported, to be broken or bent in windy weather, a small stake is set and attached to

each stem. Care is taken to keep the soil in the spaces between the plants light and free from weeds, and, should the season prove an excessively dry one, it is considered advisable to water the crop. Some growers, with a view to turn the intermediate ground to account, raise on it a crop of Beans, Cabbage, or Kohl rabi. Others condemn this practice because it lessens the productive powers of the soil, and thus has a prejudicial effect on the Asparagus. In the autumn, the dry stalks having been cut off about 2 or 2½ inches above the ground, a 2½ or 3-inch layer of good earth, and often a coat of stable manure, is put on the beds. Should a dressing of manure be applied, the strawy portion of it needs to be removed in the spring, when the ground is dug up. As to the succeeding operations, they are a repetition of those of the previous year. Respecting the application of the manure, as a rule, when the grower can command a sufficient quantity to allow of it, he puts on a dressing of stable dung, liquid manure, or some artificial fertilising material every year. When, on the other hand, the supply is somewhat limited, a dressing is only given every second or third year. Of the different artificial fertilisers, guano, superphosphate of lime, and salts of potash, applied either separately or as a mixture, are amongst the most generally employed. Some cultivators are said to have obtained highly favourable results from a combination of guano, nitrate of potash, and salt. In lieu of stable dung it is not uncommon to spread the haulm or dry stalks of the Asparagus on the ground, to add a layer of earth, and then pour liquid manure over both. Two other natural manures, which experience has shown to act most beneficially on the crop, are pigeon dung and poultry droppings. A dressing half an inch thick is applied at the end of February or beginning of March, and afterwards buried evenly. As regards the gathering of the crop, although the more general and approved practice is to defer it until the third year after planting, there are growers who begin cutting as early as the second. They cannot, however, with safety continue to gather longer than a fortnight, and require to be most cautious not to weaken the plants. When the beds are in full productiveness, May is regarded as the chief harvest month; the gathering continues, however, until about Midsummer-day. In cutting the heads, or rather, gathering them with the fingers, the grower has to exercise great care not to injure the subterranean stock. He frequently makes use of a specially constructed knife to clear away the soil from the stems.

ASPARAGUS PESTS.

Foremost amongst the causes which tend to diminish the yield of Asparagus in the neighbourhood of Brunswick deserve mention the luxuriant growth of fungus on the part of the plant above ground, the attacks of caterpillars on its roots, and the depredations of a certain beetle, *Lema* (*Chrysomela*) *Asparagi*, L. Of these the most serious evil is the parasitic fungus. With regard to the beetle alluded to, it is not so much the insect in its perfect form which proves so destructive, as the larvæ. The beetle, after eating into the vegetable, lays its eggs in the tender, juicy portion of the stalk and leaves, and when the larvæ (the produce of the eggs) issue forth, they totally destroy those parts of the plant with which they come in contact. The most efficient plan of dealing with the insect-plague is to collect and "stamp out" the young brood, or better still, the full-grown beetles, before they have laid their eggs. The work of collection must, however, be carefully proceeded with, for with the slightest movement the beetles will fall down and conceal themselves in the earth. After a time they reappear, and, if permitted, will crawl again on to the plant, lay their eggs, and recommence feeding. In his war of extermination with the beetles, the Asparagus-grower has no better friends and allies than the birds. If he is wise, he does all in his power to attract and protect them. Respecting the fungus, the first symptoms are observable in August. Small dark brown spots, which in a few days attain the length of a quarter to half a centimetre, appear on the stalks, and gradually assume a much darker shade. These spots are surrounded by the ruptured epidermis of the stalk, and are somewhat inflated. On close examination, vertical layers of small powdery spots are remarked under the epidermis: and it is their great accumulation here and there which causes the latter to burst.

The injury done to the parts of the vegetable that are above the ground has an unfavourable effect on the roots, checking their development, and in the ensuing spring the yield of Asparagus will be found materially diminished by the premature death of many of the plants. As to the precise nature and proper designation of the disease, whether rust or another disease greatly resembling it, whether originating in (or greatly increased by) over manuring with nitrogenous fertilisers, and whether—as some maintain—never met with under the shade of trees, these are questions on which some uncertainty prevails, and at the solicitation of the Brunswick Central Agricultural Association, Dr. Kuhn, of Halle, and Dr. Birnbaum, of Cleve, are now directing their attention to them. Should it be

ascertained on further investigation that the disease is not confined to Asparagus—and Dr. Birnbaum has noticed parasitic fungus almost identical in appearance on Couch Grass—the difficulty of combating the evil and preventing it from spreading will be proportionately increased. If it turns out to be rust, the spores alluded to are possibly the *Teleute*, or winter spores, which first develop themselves in spring on another plant, and are afterwards found on Asparagus in the form of mycelium or spawn. On one point, viz., the dangerous character of the disease, there is unfortunately no room for doubt, and the grower has every reason to be careful that it shall not gain ground, or be imported into districts hitherto free from it. Above all things he must endeavour to prevent the discharge of the spores—the organs of reproduction—and, as soon as any signs of disease show themselves, his best course is to remove the parts attacked and burn them.—*Field.*

LAXTON'S NEW PEAS.

THERE has been this season a great trial of Peas, by the Fruit and Vegetable Committee, in the new grounds of the Royal Horticultural Society at Chiswick. In all respects this trial has been most successful and satisfactory. Unfavourable as the season has been for most tender crops, in consequence of so much dripping wet, it has proved extremely favourable for Peas, which have seldom or never been seen under more favourable circumstances. These trials may, therefore, be looked upon as conclusive.

The indefatigable Laxton, the great Pea-maker of the day, has been reaping golden honours, having received no less than eight first-class certificates for his introductions, all of which are undoubted acquisitions in their respective classes. We have him to the front with the earliest, the latest, and the largest; and in the respective classes to which they belong, the several varieties are quite equal in flavour, if not superior, to any of the older sorts. If to these we were to add those of previous years, viz., Alpha, Supreme, Quantity, and Quality, as well as Prolific Long-pod, all established favourites, we should make out a list of Laxton's Peas more than sufficient for the largest supply.

LAXTON'S WILLIAM I.—Early green Marrow. Pods long, curved, rounded, well-filled, of a deep green colour, containing from seven to nine fair-sized deep green Peas. Very handsome in appearance, but deficient in flavour, like all others of this class. Plant vigorous, 4½ feet to 5 feet high, having the habit of the frame class more than that of Prize-taker, to which it properly belongs, producing the pods generally single, but frequently in pairs. Dried seed round, slightly indented, light green and white, mixed. This comes into use about six days after Dillistone's Early. A very excellent and first-class Pea.

LAXTON'S SUPERLATIVE.—Second-early Marrow. A cross raised between *Ne Plus Ultra* and a hybrid of *Supreme*. Pods very large, about eight inches long, slightly curved, rounded in form, and bulged out at the sides, sometimes flattened and irregular, containing from eight to ten large deep green peas, but not sufficiently large to fill the enormously large pods; flavour indifferent. Plant very robust, from seven feet to eight feet high, producing numerous pods, mostly in pairs. Dried seed light blue, parti-coloured, flattish. This comes into use fourteen days after Dillistone's. A very handsome Pea for exhibition purposes, having the largest pod of any Pea in cultivation.

LAXTON'S SUPPLANTER.—Second-early. A cross between *Veitch's Perfection* and *Little Gem*. Pods very large and broad, somewhat irregular and slightly curved, sickle-pointed, of a deep green colour, and containing from seven to nine very large Peas of a fine green colour. Plant robust, branching, about three feet in height, with large deep green foliage, producing its pods in pairs. Dried seed light blue, flat, round, like the *Imperials*. This comes into use about three weeks after Dillistone's Early. A very handsome and prolific Pea; a great improvement on *Scimitar*.

LAXTON'S FILLBASKET.—Second-early Blue. A cross between Laxton's *Standard* and *Supreme*. Pods very long, curved, round, closely filled, of a bright green colour, containing from eight to ten very large deep green Peas. Plant robust, branching, about three feet in height, producing its pods generally in pairs. Dried seed round, blue. This comes into use about fifteen days after Dillistone's Early. A very prolific and very handsome Pea.

LAXTON'S OMEGA.—Late green wrinkled Marrow. A cross between *Ne Plus Ultra* and *Veitch's Perfection*. Pods long, nearly straight, round, very closely filled, showing the Peas in the pod up to both ends, of a very deep green colour, containing from eight to ten very large Peas of a deep green colour, very sweet and excellent; inside of the pods deep green, like *Ne Plus Ultra*. Plant robust, about 2½ feet high, branching; foliage deep dark green, producing from twenty to twenty-four pods, in pairs. Dried seed deep green, wrinkled. This comes into use a day or two after *Ne Plus Ultra*, and a few

days before Veitch's Perfection, but remains green, sweet, tender, and good, several days later than either. A good name for this would have been Dwarf Ne Plus Ultra. A first-class dwarf green wrinkled Pea of the highest quality.

LAXTON'S UNIQUE.—Early dwarf green Marrow. A cross between Laxton's Prolific and Little Gem. Pods long, broad, slightly curved, scimitar-shaped, of a deep green colour, containing from seven to eight fair-sized peas. Plant having the habit of Tom Thumb, robust, about eighteen inches or two feet in height, producing from eight to ten pods in pairs. Dried seed parti-coloured, blue and white. Comes into use seven days after Dillistone's Early and two days after Tom Thumb. A very excellent early dwarf blue Pea.

LAXTON'S DR. HOGG.—Early green wrinkled Marrow. A cross between Prolific Long-pod and Little Gem. Pods very handsome, long, much curved, round, of a bright green colour, very closely filled, containing in each from eight to ten deep green peas of excellent quality. Plant rather straggling, about four feet in height, having the habit of the frame class, producing from ten to twelve pods, frequently in pairs, but sometimes singly. Comes into use eight days after Dillistone's Early. Dried seed deep green, wrinkled. A very handsome Pea, prolific, and of good quality; the earliest of the deep green wrinkled Marrows.

LAXTON'S HARBINGER.—Early round Blue. A cross between Alpha and Ringleader. Pods smallish, round, tightly filled, in appearance very much like those of Ringleader and Invicta, containing from six to eight peas of fair size, and of fine colour. The plant has the habit and character of Ringleader, and is about three feet in height, producing from seven to eight pods singly on the stem. Dried seed pale blue, like Invicta. Comes into use three days before Dillistone's Early and Ringleader, and six days before Invicta. The very earliest Pea in cultivation.—A. F. B., in "Florist and Pomologist."

ECONOMICAL MUSHROOM CULTURE.

ALTHOUGH Mushroom culture is well known, and has been often well described, there are some things still to be said, and those more especially in the direction of economical culture. Any person who can procure stable dung, good loam, good spawn, prepares them properly, and has a snug warm spot to make the bed in, can grow Mushrooms; but there are those who have not these conveniences, and yet Mushrooms may be grown, and that too at a small outlay of either trouble or expense. The great and indispensable desideratum is fermenting material of a kind that will retain a gentle heat for a very lengthened period, and for that purpose some materials may be used which have not recently been named—if at all. First among these may be mentioned sawdust which has been used for bedding horses, or for riding-school tracks. Such a substance, thoroughly impregnated with urine, and mixed with horse droppings, forms an excellent material for Mushroom beds, especially if mixed with one-fourth of good fibrous loam. These mixed and fermented together, and thrown into a bed a foot to eighteen inches in thickness, according to the temperature of the shed in which the bed is made, will be found to form capital material for growing Mushrooms, especially as it retains the heat for a long time. The worst of it is that the material is almost valueless after it has served the first purpose; and used as dung upon light land is rather injurious than otherwise. Then you may use leaves and loam in the proportion of one part of the latter in a turfy state to four or five of fermenting leaves. These may be recently gathered from the trees, and should be allowed to attain a brisk heat before the loam is added, and then, after sweating for a week or ten days, may be turned, mixing the materials thoroughly together, after which they may be formed into a bed.

A Mushroom bed of this kind should not be less than fifteen inches in thickness when thoroughly consolidated, and, so managed, it will grow Mushrooms just as well as dung. Droppings from our streets and cattle markets, especially if paved and much frequented by horses, or from cab stands, &c., if collected when dry and fermented a little, yield capital material for beds. From the cattle market we have the dung of horses, sheep, and cows mixed together in a finely divided state, the heating of which is gentle and regular. Material of this kind procured on dry days from the sanitary authorities thrown together to ferment a time or two, and then made into well consolidated beds, will produce Mushrooms of the finest quality, and continue in bearing a long time. It is of the first importance that this material be collected in a dry state, as the slush of our streets would not do at all. Equal proportions of street sweepings from those parts of towns most frequented by horses, and fresh leaves properly fermented and mixed with loam, would make perhaps as good material for the growth of Mushrooms as need be obtained. The beds, properly made and consolidated, must, if the heat be too violent, be immediately pierced with holes by a broad, blunt stick,

say a foot apart, so as to let the superfluous heat escape, and when it has done so fill up the holes again and spawn the beds. The temperature of the dung or bed at the time of spawning should not exceed 80°, indeed 75° to 80° is the proper temperature. At the time of spawning it is a very good plan to cool the beds with an inch or so of good loam, thoroughly beaten down. This is preferable to waiting until the spawn begins to spread, as at that time the check of the cold soil will throw it back for a considerable period, if not destroy its vegetative powers altogether. The right time for the final earthing of the beds is when the spawn is nicely spreading, which may be told by the white filmy appearance of the surface. The soil, if possible, should be warm at the time of using, and it will at the same time be well to cover the beds with a dry mat or two, until the surface soil attains the proper temperature.

Twelve months ago I made a Mushroom bed upon a viney floor, the dung being very roughly prepared and not very dry at the time of its formation. However, it was formed and allowed to heat, and then a coat three inches thick of strong loam from a Melon frame was forked in and made solid, and a few days afterwards the bed was spawned. I never had Mushrooms do better; they were large in size and very fleshy, and the beds continued in bearing until June. Upon the continuous bearing qualities of a Mushroom bed a word may be said. It may savour of the ridiculous to say that a plant growing upon a dung bed may fail from the want of manure. Yet such is literally and positively a fact. When beds become worn out, and the produce small and spindly, some persons directly do away with them and make fresh ones. Instead of doing this, give the bed a thorough soaking of stable urine and water at the temperature of 80°, using the urine in the proportion of one part to five of soft water, and adding a wine-glassful of salt to each quantity, then coat the bed with fresh soil, cover it with mats, so as to promote the heating, and a second crop as good as the first may be obtained. In this matter I speak from experience, and Mr. Ingram, at Belvoir, has followed the same plan for many years with the most satisfactory result. Mushrooms when in a growing state require greater supplies of water than most cultivators allow, and the produce will be much improved thereby. For the purpose of growing Mushrooms of the finest quality it will be well to cover the beds with double mats, the under one of which may be sprinkled morning and evening with tepid water, and then be covered with the dry mat. This maintains a proper growing temperature around the young plants, in consequence of which they come up juicy, and particularly rich in flavour. Mushrooms may be grown almost anywhere if the proper temperature of the bed can only be maintained; consequently the material of the bed must be such as will maintain a slow process of fermentation for a long time, and that attained, success in the cultivation of them is certain. A.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

New Early Potato.—We beg to send you a sample of a new seedling *Potato*, to be sent out by us next season, under the name of Robson's Challenge. It comes in ten days earlier than Myatt's Kidney planted on the same day. For an early kind it is a wonderful cropper, producing as heavily as any main cropping sort, and is altogether the best early round *Potato* we have seen.—PETER LAWSON & SONS. [Your seedling is a handsome round white *Potato*, which, on being cooked, was found to be beautifully white and of extra fine flavour and quality.]

Ducks in the Garden.—No more valuable help can be procured in the garden, to disturb and destroy insects, than a brood of young ducks. They devour immense quantities of slugs and other injurious pests, and in their continual ranging disturb what they do not destroy. They injure none of the vegetables, unless it may be young cabbage plants.

The Potato Disease.—This is very bad in Suffolk. It showed itself about the 1st of August, and is running in all directions on its errand of destruction with lightning-like speed. There are only two consolatory facts regarding it, viz., that many early *Potatoes* were consumed before it came, and that probably some late ones will escape uninjured.—D. T. FISHER.

Gishurst Compound.—Do your readers know that this compound stimulates plant growth as well as destroys insects? Some of my Lettices and Cabbages being attacked by insect pests, &c., I watered them well with it, and the immediate luxuriant growth was so striking, and so distinctly confined to the watered plants, that I could not but believe that the compound was the cause—I should like to know if any one else has observed this.—E. A. O.

Substitute for Potatoes.—Beet and Mangold Wurtzel would make nutritive and by no means unpalatable substitutes for the *Potato*. If these roots are boiled when the outer skin has been injured, a great portion of the most nutritious part—viz., the sugar, escapes, and the result is a tasteless, stringy vegetable; but if, instead of boiling, the roots are washed and well baked, then peeled and eaten with vinegar, they are very palatable, anti-scorbutic, and, what is a great advantage, will keep good for several days after they are cooked.—E. M. WRENCH, F.R.C.S., Exam., &c., Park Lodge, Burslow, Dorsetshire.

How to Grow Radishes.—In a late issue, one of your correspondents states that he is anxious to know how to grow Radishes with success. I have always found the following simple plan most successful: break up an old Cucumber bed and dig this in where Radishes are intended to be grown, rake over nice and smooth, then sow the seed broadcast, and sift over the bed some good garden soil, after this, pass a light wooden roller over the whole. When the plants are up, water until they are ready for use, only when the sun is shining. They will grow space, and when eaten will be found beautifully crisp and mild, and entirely free from stringy matter. Gather them when young.—T. S. JERROLD.

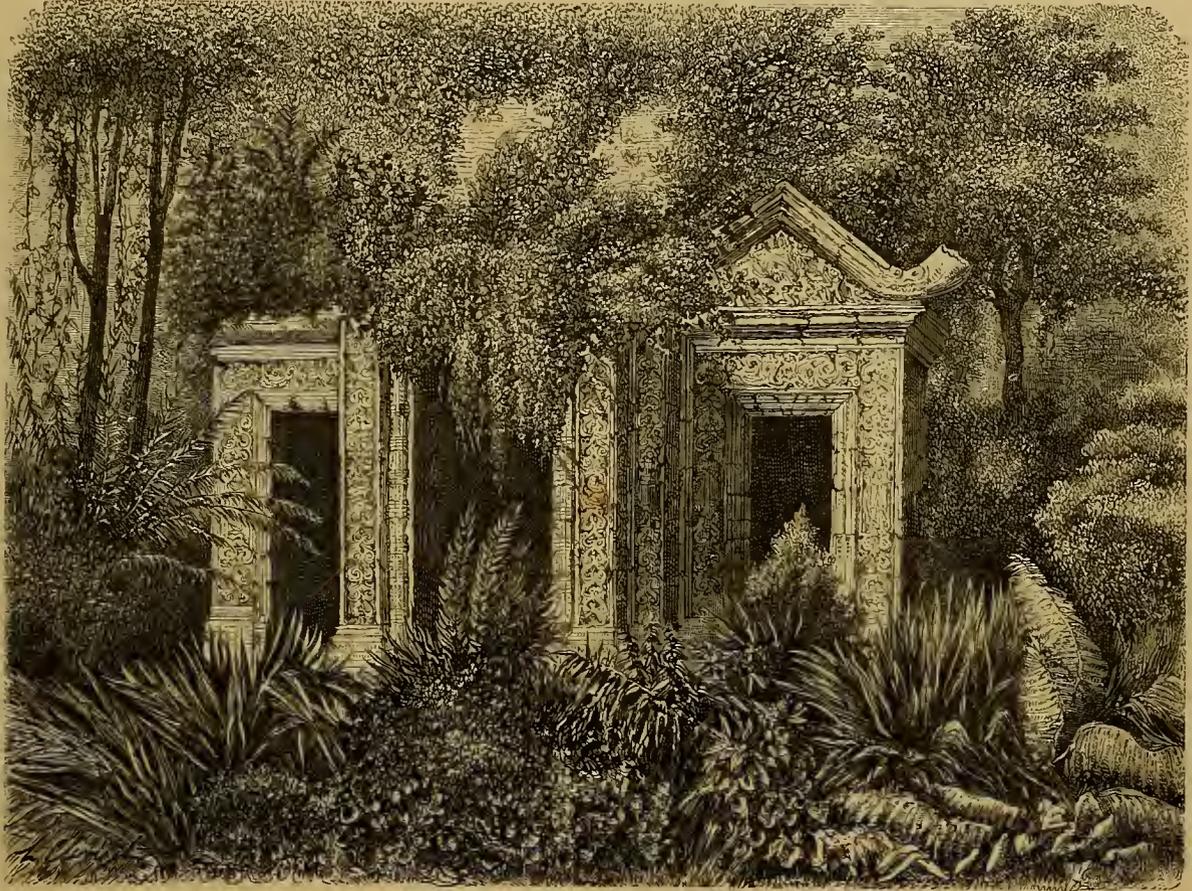

THE TRIUMPH OF VEGETATION.

"Naturam expellas furcâ, tamen usque recurret."—Horace.

WERE the surface of the earth left entirely to itself, we have little doubt that not many years would elapse ere it would present an almost uniform aspect of green, relieved only by the restless changes of the sunlit or the sullen sea. At least it would be so in all but those desert regions where drought forbids plant life. Remove man from the scene, and the ever-invading and space-appropriating forces of the vegetable kingdom, no longer checked, would quickly advance and take possession of every spot of ground from which they are now excluded by man and his works. The weeds which spring up so rapidly in our gravel walks, the grass which so soon hides the pavement of the unused court-yard, and the moss and Ivy which hasten to cover wall and roof and rock

cluding Palms, which clamber over their ruined roofs and walls. Man came in his might and built temples which are wonders even to the engineers and architects of our own day. The poor plants were not among the enemies he thought of; but they came back to hasten the mortar into dust. However, they garland the grave of a race with living immortelles, and make the scene more beautiful than it was before. Where once arose a level forest of tropical vegetation, we now see it spring from ground and wall and high cupola, and some of the aspects of vegetation among the mysterious ruins of this country are among the most strange and beautiful that are known.

A parallel case is that of the ruined cities which not many years since were discovered in the forests of Central America, completely overgrown and hidden by trees and shrubs. Of

The Triumph of Vegetation.

and tree, all attest the unceasing efforts of Nature to re-occupy her old domain. And this not merely in our moist and temperate climes. In tropical regions the silent sleepless struggle is maintained with equal tenacity of purpose, a more vigorous warfare, and more speedy conquests. Our engraving represents the ruined Buddhist shrine of Wat Phou, in Indo-China, environed and besieged by the hosts of the rampant foe. As yet have they only reached the threshold and climbed upon the broken roof, but, slowly yet surely, the time will come when roof and wall shall be prostrated by the sturdy climbers and form a rubbish-heap on which the descendants of the Dracænas, Ferns, Cycads, and other plants which now swarm in the foreground, shall establish themselves in triumph, and live and reign in undisputed possession. In the same country there are many wonderful old temples, some of them of vast size, which are gardens, from the number and profusion of the plants, in-

the race of men who built them no trace remains to us, and they probably passed away from the earth long before our history commenced; but the carvings on the fragments of stone which have been disinterred from the mounds of ruins prove that they possessed no contemptible knowledge of the arts which belong to civilized life. Everything relating to them has vanished, save these relics of their dwellings, and the once busy scene of their life is now buried in the deep silence and impressive solitude of the forest, whose towering trees have usurped the place of all that once belonged to them, and now stand victors over their ashes.

A FEARFUL fire, says the *Levant Times*, has taken place at Rodos, which has completely destroyed the forests on the island of Simi. The conflagration, which appears to have rivalled in extent the prairie fires of America, reached from Boudroum to Marmora, a distance of 70 miles.

THE ARBORETUM.

THE NEW FOREST.

A FOREST officer has lately contributed to the *Times* some sensible remarks on this and similar lands: "I think it desirable," he says "that it should be borne in mind that when we talk of the forest as 'belonging to the Crown,' 'the rights of the Crown' therein, &c., we really mean by 'the Crown' the State or the Government, for, *de facto*, the property is as much public as if it had been formally transferred *in perpetuo* instead of from reign to reign. I consider the idea that the New Forest is Crown property, or that the Sovereign has personal rights in it, erroneous, and likely to lead to false impressions, as, indeed, it has done, and that the whole question must be considered as one between the public or the State, as represented by the Government and their servants, and the privileged few who have certain rights in the forest and who are styled 'commoners.' Any other view, is, I consider, mischievous, as it would represent the interests of the Crown as antagonistic to those of the State, whereas they are identical. In fact, I would ask all interested in the subject to bear in mind what is, indeed, generally known, but not always thought of—viz., that the 'Crown lands' are so merely nominally, and that the New Forest is to all intents and purposes public property. I would also call attention to the fact that up to the present time the commoners have got the best of it in every readjustment or attempt at settlement of the forest, notably under the arrangement provided for by the Deer Removal Act, in 1851, in which case 'the deer have been removed, and each commoner's right investigated and entered in a register, but the Crown is not yet in possession of even the immediate compensation secured to it by the Act, for it has only enclosed one-half out of the 10,000 acres.' In fact, the commoners have so managed as to engender and keep alive a belief that their cause is identical with the popular one, while, in my opinion—and I have had some years' experience, and studied the subject both in India and the Continent of Europe—it is exactly the reverse. I submit that commoners are the natural enemies of all such public property, and that it is expedient to buy them out or commute their rights and servitudes at any price. Such has been done in Saxony thirty years ago, and both the State and those who had rights are convinced that it has proved a most advantageous step for both parties concerned, although at the time both were dissatisfied. The re-arrangement would be best effected by the appointment of a mixed Commission to value all such rights of which a complete register already exists, and submit definite proposals for buying them up, which might, after due consideration in Parliament, be embodied in a Bill and carried into effect. Then, and not till then, the New Forest might be dealt with as a purely national property, and administered to the best advantage by responsible officers subject to Parliamentary control.

I can see no reason why we should not then make of these 109 square miles, now lying more or less unproductive, a State forest of great value, managed on principles of scientific forestry, and at the same time forming a recreation ground for the people, free to all without let or hindrance, save in the case of young plantations where much damage might be done by the admission of men or cattle. I am not sure that even these need be enclosed if a proper act were passed authorising the punishment of trespassers and pounding of cattle found within the prescribed limits, and if the whole subject of a national forest conservancy, its uses and advantages, were made generally known to and understood by all classes. I maintain, further, that the proper management of a forest to the best advantage as a timber-producing area is scarcely, if at all, antagonistic to its retention as a picturesque and agreeable recreation ground, and that by judicious management we may secure the threefold advantage of—1. A considerable surplus revenue, derived without damage to the capital or stock of wood in the forest. 2. A large supply of timber for building purposes and firewood. 3. The preservation of an extensive area as a national recreation ground and the grazing of cattle under certain restrictions, and, if necessary, on payment of a small fee per head. On the first point there can be no reasonable doubt that, if the whole or greater part of the area were considered as available for planting and treatment as a forest, a very large annual income would before many years accrue to the State. Even as it is, with only some 25,000 acres under wood, the great proportion of which consists either of very young plantations or tracts containing only very old and scattered trees, there was a net balance of upwards of £4,000 for the year 1870-71, and I have no hesitation in asserting that this amount might be increased tenfold before the close of the century, while the value, beauty, and usefulness of the forest would have increased in equal, if not still greater, ratio. Nay, I have little doubt that much of the 30,000 acres classed as 'barren heath and moorland, utterly

unproductive,' might and would be gradually reclaimed and covered with timber if matters were put on a more definite and satisfactory footing, and the forest officers allowed to do the best they could for the State property under their charge, and not tied down to planting a comparatively small area, for which it is natural they select tracts presenting the fewest natural difficulties. On the second point I would remind your readers that the supply of timber from abroad is not inexhaustible, and that even now we hear ominous rumours of its becoming scarce in accessible localities in Norway and Canada, while I can vouch for the difficulty of keeping up the supply of teak from India and Burmah. Again, looking to the existing price of coal, and the probability that it will each year become dearer and scarcer, it appears worthy of consideration whether the practice of burning wood might not partially be re-introduced, and with this object the rearing of plantations of quick-growing trees, and encouraging the growth of Beech under Oak (which is universal in Germany), become a matter of paramount importance. England may be said to be the only European nation which has no State forests, properly so called, and I cannot help thinking that it is high time that she followed the example of other nations even in a tentative manner, and we have in the New Forest an excellent field for a commencement. Turning to the third point, I admit that the natural result of the introduction and carrying out of a system of scientific forestry is to convert many sunny glades and open pastures into 'dense Fir plantations,' and to substitute useful but unpicturesque stems 'drawn-up' to 40 or 50 feet without a branch, in place of the garbled Oak or the spreading Beech; but I think the general effect of this is exaggerated, and that even without special endeavour to preserve and set aside portions of the forest as open or park land, to be managed, as is the case in Windsor Park, only for the sake of the picturesque (and this could easily be done if thought expedient), there would still remain ample field for the lover of the beautiful and the natural in the varied and ever-changing forest itself, containing timber trees of various descriptions and of all ages, self-sown or planted, some ripe for the axe, some only just emerged from the nursery, and some patriarchs left towering alone to reproduce their species after all their contemporaries had been cleared away and converted to useful purposes. To any who doubt this I would say, go to Hanover and visit the Communal Forest of Eilenried, in close proximity to the town, and forming at one and the same time a most valuable property and a most lovely and picturesque recreation-ground; or let them proceed to the far-famed Wiener Wald, a State forest of 60,000 acres close to Vienna, and watch the pleasure-loving populace of that gay capital streaming forth every Sunday and holiday to ramble in the Beech woods and admire the beauties of nature, and I think all will readily admit that it is possible to retain the beautiful and picturesque along with the most useful and profitable.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Hydrangea paniculata grandiflora.—This is a good companion to the Oak-leaved *Hydrangea* lately mentioned in our notes. In colour of flower it resembles that kind, but it is quite distinct in habit. Free-flowering specimens of it may now be seen in some of the metropolitan nurseries.

Cupressus Lawsoniana alba pendula.—This new conifer is now in beautiful condition in the Cheshunt Nurseries. The present seems the season in which its silvery hues are brightest, just as the golden colour of *Thuja aurea* is most effective in April.

Acacia Hedges.—People who cannot get white thorn to grow as hedges in dry arid soils, where one often sees the most miserable of stunted moss-covered fences, should plant the common *Acacia*: it will thrive in such soils, and quickly form a strong fence. In very moist situations, in which the thorn is equally a stranger, good fences may be made by planting Willows, and, if good sorts are selected, the hedge becomes a source of profit.

Large Trees.—On the estate of the Count de Dree, in Côte-d'or, are two Plane-trees of remarkable size. The trunk of one of them, close to the ground, measures more than 27½ feet in circumference, while at a height of 6½ feet from the ground it has a girth of over 16½ feet. The other is of still greater dimensions, its trunk measuring over 29 feet in circumference close to the ground, with a girth of nearly 18 feet at a distance of 6½ feet from the ground. The diameter of the area covered by one of these trees is 162½ feet. There are many other large trees on this property—among them some specimens of *Populus fastigiata*, with stems from 9 feet to 13 feet in circumference, and a *Juglans nigra*, the stem of which at a height of 6½ feet from the ground has a girth of 7½ feet.—*Revue Horticole*.

AYRTON *v.* HOOKER.

As one of your contemporaries has been indulging in some little attempt at epigram on this subject, perhaps you will kindly allow me to follow suit with a tiny bantering:—

"If Kew's Director would resign
All work as boiler-overlooker,
And 'hook it' to his proper line
He'd act like a 'judicious Hooker.'"

T.

THE HOUSEHOLD.

THE HORSE MUSHROOM.

(AGARICUS ARVENENSIS.)

THIS species is very nearly allied to the Meadow Mushroom, and frequently grows with it, but it is coarser, and has not the delicious flavour. It is usually much larger, often attaining enormous dimensions, and turning a brownish yellow as soon as broken or bruised. The top in good specimens is smooth, and snowy white; the gills are not the pure pink of the Meadow mushroom, but of a pale brownish-white, ultimately becoming brown-black. It has a big, ragged floccose ring, and the pithy stem is inclined to be hollow. It is the species exposed for sale in Covent Garden Market. Indeed, after knowing the market for many years, I have rarely seen any other species there; when the true Mushroom, however, is there, it is frequently mingled with the Horse Mushroom, which seems to show that the dealers do not know one from the other. In the wet days of autumn, poor people go a few miles from town into the meadows to gather whatever they can find in the Mushroom line; they then bring their dirty stock to market, where it is sold to fashionable purchasers, stale, ravid, and without taste—unless it be a bad one. When young and fresh, the Horse Mushroom is a most desirable addition to the bill of fare: it yields an abundant gravy, and the flesh is firm and delicious. It is a valuable plant when freshly gathered, but when stale it becomes tough and leathery, and without aroma or juice. There is a curious, large, brown, hairy variety, of

Agaricus arvensis (Horse Mushroom). Pastures, in autumn; colour, yellowish white; gills pallid, at length black; diameter, 6 to 24 in.

rather uncommon occurrence, similar to the hairy variety of the Meadow Mushroom, the *A. villaticus* of Dr. Badham. It is a fine form, but, I think, very rare. I have only seen it once. Many country-folks readily distinguish the Meadow from the Horse Mushroom, and show antipathy to the latter, although they are always willing to put it into the jar as one of the ingredients of ketchup. Opinions appear to differ greatly regarding the excellence of this species. Mr. Penrose writes:—"I think young, and especially button specimens of this very indigestible; until they are well opened out, they are unfit for use." Such, however, I must say, is not my experience of button specimens. There is a strong odour attached both to the fungus and the spawn, the ground just below the surface being frequently white with the latter; or if horse-dung be kicked aside in a rich meadow frequented by graminivorous animals, the earth will frequently present a snowy whiteness, from the spawn of this species, from which the young individuals may be seen springing up. I once saw a sheep eat a large specimen with great apparent gusto, although the fungus was full of maggots. Pileus fleshy, obtusely conico-campulate, then expanded, at first floccose, then smooth, even, or rivulose; stem hollow, with a floccose pith; ring broad, pendulous, double, the outer split in rays; gills free, wider in front, at first dirty white, then brown, tinged with pink.

Cottage Cookery.—Now when the Potato disease is likely to leave us without Potatoes, perhaps a word or two on this subject may not be without interest. Food for working people must not only be as substantial as possible, but it must also be made savoury to be properly relished. It is in this particular that cottage cookery is most deficient, though in ancient times books indicate that many things were used to give flavour that are now neglected—Marigold flowers for instance. It is for want of savouriness that soups and stews have acquired the derogatory name of *messes*. It was to give savour that Count Rumford added salt herring to his cheap dishes; it is in this respect that French cookery for all ranks surpasses that of England; and until our housewives become instructed in the means of obtaining savouriness, economical cottage cookery is not to be hoped for. But how is this desirable quality attained in France? It is by the habitual employment of matters that give flavour; in the poor man's cottage those of little cost. A gentleman's cook would be thought shabby if asking at market for less than a sou's worth of "*herbes pour le pot au feu*," but the poorer orders are habitually served with a farthing's worth of vegetables for their soups; for their farthing they obtain a very small Carrot, a small Turnip, Onion or Leek, either full-grown or green, including green leaves, a sprig of Thyme, a little Mint, Parsley, or in lieu of it green tops of Celery, and to complete the vegetable ingredients of the soup either some Lettuce or Endive, often the surplus of a seed-bed, or plants not promising to come to perfection as salads. What would our cottagers say on being supplied with green leaves of Celery? Yet in France they are often substituted for Parsley. So many articles that we throw away are used for giving flavour in France; as the rinds of Oranges, for instance. Our Carrots and Turnips are too large to be only part of a farthing's worth; but why should not these roots be cut up for sale at petty stalls? The cottager has in respect to vegetables a great advantage over the townsman, for in the country an allotment will furnish a variety of vegetables by cultivating it only at odd times; even the yard of small cottages may be made to grow Parsley, Thyme, and other sweet herbs; but a first need is that of teaching housewives how to make good use of the products of their garden by a superior mode of cookery.

NOTES AND QUESTIONS ON THE HOUSEHOLD.

Rice.—This would make a good substitute for Potato food. It is particularly nutritious, and well adapted for use as a vegetable, especially in place of Potatoes, as the mode of cooking it is similar—simply boiling, and it has this advantage, that there is no waste whatever in the preparation for use. It is sold at a low price, and this year especially so, being about 1½d. per lb., or even less if taken in quantity: and 1 lb. of rice is fully equal, I consider, to 2 lbs. of Potatoes.—AN OLD INDIAN.

Horse Mushroom Ketchup.—Are Horse Mushrooms fit to make ketchup with, or is it not proper to use them for that purpose? There are so many Horse Mushrooms this year in proportion to the true meadow ones, that I am induced to make the inquiry.—W. D. [Ketchup made from Horse Mushrooms is very good and wholesome, but not quite so delicate in flavour as that made from the true Meadow Mushroom. The ketchup of the London markets is made almost exclusively from the former, with any fungi added, capable of yielding a black juice.]

Pilaf: a Turkish Dish.—Take three or four large tomatoes and boil them. When they are quite soft mash them well, adding a little salt, and put them back in the same water in which they were boiled, and add half a pound of rice. When the rice has absorbed all the water, and is well done, take the saucapan off the fire, and put it to stand near, so as not to cool; then put a good-sized piece of butter in a frying pan, and when it is well browned mix it up well with the rice, and serve it hot. It can also be made with bouillon in the place of butter.

Artichauts farcis à l'Italienne.—Trim off the top of the leaves of the Artichokes. Boil them for twenty minutes in salted water with the juice of a lemon. Drain them thoroughly. Take some anchovies; bone and wash them clean; then mince them finely with a small quantity of garlic; add some powdered thyme and pepper and salt. Open out the leaves of each Artichoke without detaching them; insert a small quantity of this mixture between each leaf. Tie up each Artichoke with thread; place them close together in a tin; pour plenty of olive oil over them; lay a piece of oiled paper on the top, and set them in the oven for about half an hour. Remove the threads before serving.

—Trim off the top and parboil them sufficiently to allow the small leaves and stem inside to come off easily; open out the leaves and remove the inside with the handle of a silver spoon. Mince very finely some ham and half its bulk of beef suet; add a small quantity of chopped shallot or garlic, pepper, salt, and minced or powdered sweet herbs to taste; then the same quantity of fine bread crumbs as of suet and the yolks of two or more eggs. Mix the stuffing well together, and fill the inside of each Artichoke with it. Pour two table-spoonfuls of olive oil into each, and finish as in the preceding recipe.

Stuffed Vegetable Marrow.—Pound to a paste in a mortar slightly rubbed with garlic, equal parts of veal and of ham; then pass them through a wire sieve, and return them to the mortar. Work into the paste thus obtained a fourth of its bulk of butter, and about the same quantity of bread crumb, with the yolks of one or more eggs, according to quantity. Add some minced parsley and, according to taste, pepper, salt, spices, and powdered sweet herbs. Cut in half lengthways a couple of average-sized Vegetable Marrows; take out the inside, fill each half with the stuffing, and wrap it up in a piece of thin paper well buttered and tied with string; lay them all close together in a buttered tin, cover this up with a plate or another tin, and put it into the oven. When you judge the marrows are quite done take them carefully out of the papers, lay them on a dish, and serve with a small quantity of well-flavoured clear gravy or some Tomato sauce poured over them.

THE FRUIT GARDEN.

THE GUAVA.

THE fruit of the Guava in its fresh state, like the Banana, is only really appreciated by those who have acquired a taste for tropical fruits. Nevertheless, it makes a very nice addition to the dessert, and as the Guava is of easy cultivation, one is surprised that it is not more generally met with. The Psidium Cattleianum is one of the very best, and is the kind from which the Guava jelly of commerce is made. Like all the genus it is a handsome evergreen shrub, sometimes attaining the height of 20 feet, bearing freely its purple, oblong, pear-shaped fruit, somewhat larger than the Morello Cherry. It may be grown in pots or on the back walls of early vineries; and as it makes a very ornamental wall plant, it might also be planted against the back walls of warm conservatories, as its white flowers are very beautiful. However, the best example of its cultivation I have ever met with was growing near the glass, trained to a wire trellis, something after the fashion of the Peach, but wherever grown, light is necessary to mature the wood. It might be grown successfully in any moderately warm plant house, where a little shade was not objected to, and trained under the roof, as by thinning the small branchlets in autumn, the obstruction to light would be considerably reduced in winter. The Guava is not particular as to soil, but a good turfy loam slightly enriched suits it best. It should be planted in a well drained border, as during its growing and fruiting season it requires a good supply of water, with occasionally a soaking of weak liquid manure. Like all the members of the Myrtle family, it is very subject to be attacked by thrips. It should therefore undergo a thorough cleansing every winter with soft soap, and the syringe should be used freely during the spring and summer months, when occasional fumigations of tobacco that will, in all probability, be required by the other occupants of the house, will generally keep it clean. There are one or two species that bear yellow fruit, but all are evergreen and have white flowers and are equally easy of cultivation.

E. HOBDAV.

ROOT PRUNING.

FOR promoting the fertility of fruit trees, root pruning is an operation now generally resorted to. If properly carried out, it is perhaps the most certain way to reduce a luxuriant tree to a fruitful state. We wish to emphasize the word *properly*, because it is quite as possible by root pruning to reduce a tree to a state of permanent sterility as to make it fruitful. Fruitfulness in trees of luxuriant habit, such as Apples, Pears, and Plums, and, in fact, in all other trees, depends upon that balance of force between the roots and branches which, while it ensures sufficient force in the branch, at the same time promotes the complete maturation of the wood, and thus the formation of flower buds. To hit the happy medium, to so balance the forces of the tree that fertility shall be attained without merging either into luxuriance or weakness, constitutes the success of the careful cultivator. If, however, trees are planted and, as is frequently the case with amateur cultivators, are allowed to grow on and on for years with the expectation that they will grow into fruit, the cultivator must not be surprised, if root pruning is resorted to and not very carefully carried out, to find his tree thrown into a state of unfruitfulness—sterile, in fact, until such time as sufficient force is again accumulated to form healthy growth. Fortunately, however, our leading nurserymen are so particular in the stocks they make use of, and resort so systematically to root-pruning and transplanting, that it is only by bad management after the plant leaves the nursery that the balance of force will be disturbed. Such disappointments, however, do occur, and generally result from mistaken kindness in using rich soils and manures. When the luxuriant habit is induced, the wood formed is too strong and sappy to form flower buds, and hence barrenness is the result. This may arise from over-rich soil, or from one or more roots rushing away deep into the subsoil, where they suck up such crude matter that growth is promoted late into the autumn instead of being brought into a maturing state not later than the middle of August. With the luxuriant tree, and when the luxuriance is the result of over-feeding for a series of years, the best plan will be found to lift it out carefully from the place in which it has been growing, to shorten in the strongest roots, and to plant it again almost upon the surface of the ground, using a little fresh soil

around the roots, and mulching the surface of the ground with some spent dung or leaf-mould. Carefully staked to prevent wind-waving, and the branches judiciously thinned out in early spring, and those retained shortened back, such a tree will be moderated in its growth the following season, and will almost invariably produce abundance of fruit buds. But if the check is too great, sterility may be the result for a year or two, which sterility will be the more quickly overcome by liberal treatment. So far, the treatment of unfruitful trees may be said to be confined to those only recently planted. When trees of more mature years are barren, then more cautious treatment must be resorted to. For example, nothing is more common than for Pear or Plum trees, of large size, when trained against a wall, to be entirely fruitless. To take up such trees and replant them would not generally be the right thing to do, because being of mature growth, the check of complete removal might be too great. In such cases the best thing is to commence at the extreme point of the roots, and to lift them, according to the size of the tree, to within two, four, or six feet of the main stem, and then to relay the roots near to the surface of the ground; or, in the case of wall trees, half the roots may be taken up one season, following them to the very base of the stem, and the remaining portion, if necessary, the following season. Such treatment cautiously followed out will generally restore the balance of force, and with it fruitfulness must ensue. Now come we to the ordinary trees—such as are prepared by root pruning before they are sent out from the nursery, and may be said to have been reduced to a moderate and healthy state of growth. These sometimes, if transferred to a rich soil, may start after a time into an over-luxuriant habit. In such a case it is customary to check them by root pruning, simply by digging round one side of the tree this year, and cutting off some of the stronger and more perpendicular roots, and treating the other portion in the same manner the following year. Early autumn, while there is yet some heat in the ground, is the best time for root pruning, as the warmth enables the wounds to heal quickly, and also to throw out fresh feeders so as to become re-established before the active growth of spring commences. Trees thus managed, with bi-annual attention to root pruning, may be easily kept in a constantly fruitful state, and for small gardens nothing looks so neat as bush or pyramidal trees so managed.

R.

How to Destroy Moss and Insects on Fruit Trees.—

Last year some fruit trees on the property of M. Adam, at Chapelles, Indre, an amateur horticulturist, were covered with moss and insects. This season the same trees can hardly be recognized, their bark being smooth, glossy, and healthy. M. Adam explained the cause of the change, and gave his recipe, which has been tried. I have modified it a little, and can advise all annoyed with either moss or insects to daub or besmear their trees from top to bottom with the following composition:—Boil two gallons of barley in water, and then take out the barley, which can be given to the fowls. In this water dissolve three gallons of quicklime. When it is cold mix two pounds of lamp-black, mixing it for a long time with a stick; then a pound and a half of flowers of sulphur (brimstone) and a quart of alcohol. Daub the trees with this by means of a paint brush, after having scraped off the moss with a rough brush. This composition destroys the cocoon (Chermes), the grub (plant louse), moss, and all insects, gives strength and suppleness to the bark, and certainly revives the aspect of fruit trees.—*Ed. André, in "L'Illustration Horticole."*

Greeley and his Pumpkins.—Mr. Greeley is a great man in the art of cultivating Pumpkins. The fame of Greeley's Pumpkins reached the ear of Mark Twain, and being of an inquiring turn of mind he interviewed the great man. The result of Twain's "pumping" is given in the form of a report in the *Pittsburg Gazette*. Mr. Greeley, says Twain, exhibited to an agricultural club a Pumpkin of his own raising. As it embodied his solitary and crowning success, after several years of discouraging failure in Pumpkin culture, the club surrounded it with uncovered heads and mingled motions of surprise, admiration, and envy. It was a superb fruit; and when Mr. G.'s hat was placed on it, to illustrate its size and symmetry, the hat and Pumpkin seemed so perfectly adapted to each other, and together produced an effect so startling, that several enthusiastic members swore they would have known who had raised that Pumpkin if they had seen it anywhere.

Eating Mangoes.—At a dinner-table you have to scoop out what you can of them (the large stone being in the way) with a spoon, but enthusiastic admirers of the fruit suck at it in undignified fashion, take off their coats to the work, and provide for the flow of the juice over their hands and arms by having a bowl (a finger-glass is ineffectual fooling)—a big bowl of water to wash in during the process. I have heard men say that when they give up an afternoon to Mangoes, they would not let their best friends behold them. Some, indeed, settle any question between finger-glasses and buckets, by getting into their baths at once when they court the adored fruit.—J. M.

GARDEN DESTROYERS.

THE NEW VINE PEST.

(PHYLLOXERA.)

WHEREVER this insect has been noticed, both the leaf gall-inhabiting and root-inhabiting types have been found, and I consider the gall-louse and root-louse identical. I have successfully transferred the leaf-lice on to the roots, while others have succeeded in obtaining leaf-galls from lice hatched on the roots, and the winged form obtained from galls in this country agrees in its characters with those from the roots. Moreover, the nodosities on the roots are perfectly analogous to the galls on the leaves, and differ only in just such a manner as one would expect from the difference in the plant tissues—a view greatly strengthened by the fact that when the gall-lice are forced, by their excessive numbers, to settle on the tendrils or leaf-stalks, they produce swellings and knots approaching more nearly to those on the roots than to the galls. These facts sufficiently attest the identity of the two types, and thus we have a case of an insect possessing two distinct habits. It is also like many others of its family, polymorphic, *i.e.*, it exists in different forms; yet we have to do with but one species.

FURTHER FACTS RESPECTING ITS HABITS.

The young hatched from eggs on the roots are absolutely undistinguishable from those hatched in the galls; and the gravid apterous female differs in no respect whatever from the mother gall-louse. There is, however, a different egg-depositing form, which, as it moults, becomes tubercled, and more elongated or pear-shaped, as shown in our illustration at *j*. Some of these tubercled individuals remain without wings, while others seem to be destined from the first to acquire wings. The young, after attaching themselves, become in a measure stationary, and remind one very much of young bark-lice. The fine hair-like setæ, which in their functions and elasticity are analogous to our tongue, become loosened from the more fleshy rostrum or sheath, as shown at *j*, and are often so firmly inserted into the root that the louse, if disturbed from its place, generally hangs by them. Three of the threads of this tongue are sufficiently conspicuous, but there should be, from analogy, four. The females on the roots seem to be less prolific than those in the galls, and their eggs if anything are rather larger. These eggs are always of a bright yellow colour, and, on the dark root, are detected with the naked eye as readily as the lice, which become darker or of a dull orange as they grow older.

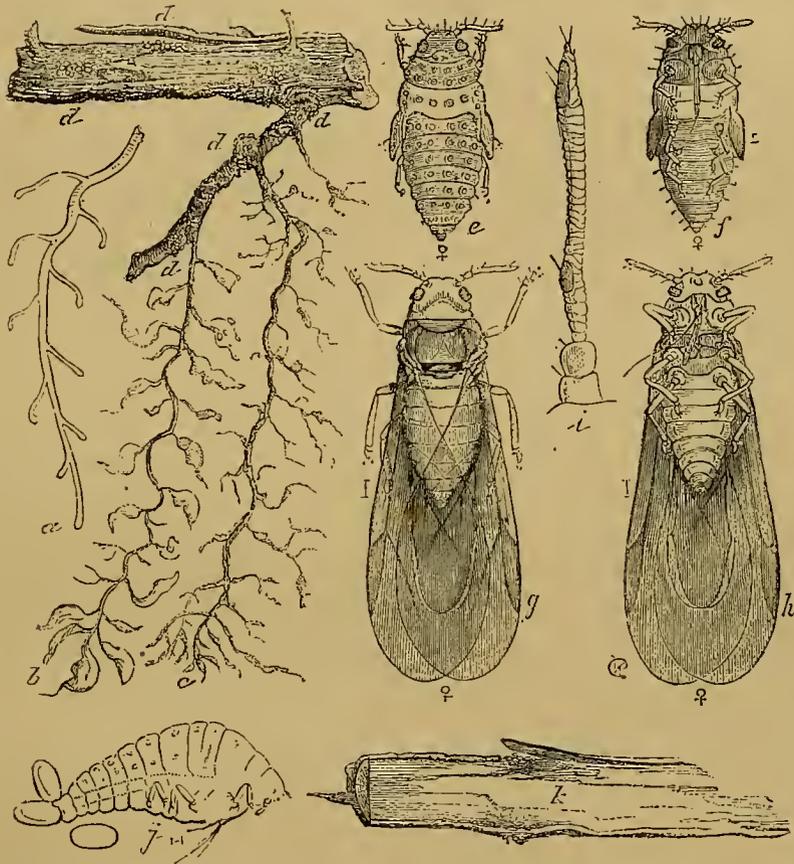

The insect is found on the roots in all stages during the

summer months. In the winter it is found dormant, principally in the larva state, and no eggs are to be seen. With the circulation of the sap in spring, the activity of these young pests recommences, and in a short time afterwards eggs are deposited again. At this season the punctures of their little beaks produce very decided swellings and an excess of moisture at the wounded parts. The winged forms are by no means uncommon, and commence to issue from the ground perhaps as early as July. The pupæ are easily recognizable with a good lens, by the little dark pad-like wing-sheaths at the sides of the body, and the sexes may even be distinguished at this stage by the greater constriction of the body near these pads in the female, compared with the male, her abdomen being larger. Before giving forth the winged insect, these pupæ become quite restless and active, and in a state of nature they no doubt issue from the ground.

The winged female seems to be much more common than the male, and is distinguished by her more lengthened abdomen—the wings, when closed, extending not much more than its length beyond the tip, while in the male they extend more nearly three times its length.

In European varieties the roots get badly affected, but there are no leaf-galls. In American vines both roots and leaves get affected, but it has been noticed that where leaf-galls are few, root-lice have been abundant, and *vice versa*. Few vines are entirely free from the attacks of the root-louse; but the European varieties are most susceptible to it—the Northern Fox next in order, the River Bank Grape next, and the Summer Grape the least affected. From examination, it would likewise appear that galls are occasionally found on all species except the European, but as they have in a few instances been found on this species in Europe, it cannot be considered

entirely exempt. Indeed, I have been informed by Mr. Glover, of the Department of Agriculture, that the leaves of certain European vines, in greenhouses, such as Muscat, Hamburg, and Mrs. Pince were covered with the galls, even as late as December, and that they had begun to spread on to several other kinds of vines. In America, in general terms, the River Bank Grape must be considered the species which the gall-louse prefers, but no vine, whether native or foreign, is exempt from the attacks of the root-louse. Yet, on the principle that a small dose of poison may prove harmless or even beneficial where an over-dose will kill, we find that a small number of root-lice produce no serious effects upon the vine; and that it is only where they are very numerous, and cause not only the fibrous roots, but even the larger ones to waste away, that their evil effects are per-

REFERENCES.—*a*, shows a healthy root; *b*, one on which the lice are working, representing the knots and swellings caused by their punctures; *c*, a root that has been deserted by them, and where the rootlets have commenced to decay; *d, d, d*, shows how the lice are found on the larger roots; *e*, female pupa, dorsal view; *f*, same, ventral view; *g*, winged female, dorsal view; *h*, same, ventral view; *i*, magnified antenna of winged insect; *j*, side view of the wingless female, laying eggs on roots; *k*, shows how the punctures of the lice cause the larger roots to rot.

ceptible. In France, according to M. Laliman, the American varieties which have resisted the root-louse best are the Clinton, Taylor, Herbemont (known there as Warren), and some others which are considered valueless here, such as Pauline, Elsimboro, Lenoir, Mustang of Texas, and a kind of York-Madeira; while those which succumb are Isabella, Scuppernong, Concord, Norton's Virginia, Maxatawny, Hartford Prolific, Cynthiana, &c. This experience differs a little from ours, but shows that the *Labruscas* suffer most.

MEANS OF CONTAGION FROM ONE VINE TO ANOTHER.

The young lice, whether hatched upon the roots or in the galls, are quite active, and crawl about for some time; and that they will spread from one vine to another, either underground upon the roots, or on the surface of the ground during the night, is highly probable. Such, however, cannot be the mode of spreading from one vineyard to another; for were it so, the malady could not possibly have assumed such proportions in so short a time as it has done. One method of transport is upon the roots of seedlings and cuttings, but the insect cannot in this manner find its way to an old vineyard, and there must be still another means. In this country the malady is general, but in France, where it is still spreading from one place to another, they have a good opportunity to watch its progress; and Planchon finds that it always commences at certain circumscribed points, and spreads from these points in more or less regular circles. There is no way of accounting for these nuclei—these starting points in the centre of an old vineyard that never showed signs of the disease before, except on the hypothesis of the winged insect having flown there and started the colony. We have already seen that certain individuals of the root-inhabiting type become winged. Why these individuals become winged while others never do, is, perhaps, not for us to understand; but our winged female *Phylloxera* is a reality! What, then, are her functions? In the breeding jars she invariably flies towards the greatest light, and her large compound eyes and ample wings indicate that she was made for the light and the air. We have also seen that she is burdened with two or three eggs only, and my opinion is that her sole life duty is to fly off and consign her few eggs to some grape-vine or grape-bud, and that the lice hatching from these eggs constitute the first gall-producing mothers.—*Riley's Report on Noxious Insects, &c.*

(To be continued.)

DRYING PLANTS.

As regards the best mode of drying plants, so as to preserve their colours, *Science Gossip* has the following:—The materials required are common cartridge paper, thick white blotting paper, cotton wadding, and millboard, all cut to the same size. The plants should be gathered in dry weather, and soon after the flowers open, when their colours are brightest. Succulent plants (such as Daffodils, Orchis, or Stonecrop) should be put into scalding water, with the exception of the flowers, for a minute or two, then laid on a cloth to dry. Arrange the specimens and paper in the following order:—Millboard, cartridge paper, wadding (split open, and the glazed side placed next to the cartridge paper), blotting paper; the specimens having small pieces of wadding placed within and around the flowers, to draw off all the moisture as quickly as possible; blotting-paper, wadding as before, cartridge paper, millboard. When the specimens, &c., are thus arranged, heavy weights should be put on them; about 30 lbs. the first day, 60 lbs. afterwards. Remove them from under pressure in a day or two; carefully take away all the papers, &c., except the blotting-papers between which the specimens are placed; put these in a warm air to dry, whilst the removed papers, &c., are dried in the sun, or by the fire. When dry (but not warm) place them in the same order as before; put all under the heavy pressure for a few days, when (if not succulent) they will be dry. Flowers of different colours require different treatment to preserve their colours. Blue flowers must be dried with heat, either under a case of hot sand before a fire, with a hot iron, or in a cool oven. Red flowers are injured by heat; they require to be washed with muriatic acid, diluted in spirits of wine to fix their colour. One part of acid to three parts of spirit is about the proportion. The best brush with which to apply this mixture is the head of a Thistle when in seed, as the acid destroys a hair pencil, and injures whatever it touches (except glass or china); therefore it should be used with great care. Many yellow flowers turn green even after they have remained yellow

some weeks; they must therefore be dried repeatedly before the fire, and again after they are mounted on paper, and kept in a dry place. Purple flowers require as much care, or they soon turn a light brown. White flowers will turn brown if handled or bruised before they are dried. Daisies, Pansies, and some other flowers, must not be removed from under pressure for two or three days, or the petals will curl up. As all dried plants (ferns excepted) are liable to be infested by minute insects, a small quantity of the poison, corrosive sublimate, dissolved in spirits of wine, should be added to the paste, which it will also preserve from mould. The best cement for fixing the specimens on to the paper or cardboard is gum paste. It is composed of thick gum-water and flour mixed in warm water by adding the two together, warm, and of a consistency that will run off the hair pencil.

MEMORANDUM OF THE FIRST COMMISSIONER ON THE MANAGEMENT OF KEW GARDENS.

(Continued from p. 189.)

THE APPOINTMENTS BY COMPETITION.

ONE more topic raised by Dr. Hooker which is of public interest remains to be noticed. On the introduction of the system of appointment by open competitive examination, the First Commissioner agreed to surrender to the Civil Service Commissioners his right to nominate to any subordinate technical office in the Department of Works. The system under her Majesty's Order in Council has been found to work admirably for the purpose of providing technical officers. Two cases have occurred in which subordinate offices in Kew Gardens have had to be filled. Dr. Hooker has desired to nominate the person to fill the vacancy in each case, but the First Commissioner has declined to reverse the open competitive system; in one of the cases the system has been eminently successful, in the other it has failed; both are instructive examples. A vacancy being imminent in September 1871 in the office of junior assistant in the herbarium, Dr. Hooker recommended a person to fill the vacancy; he was then informed of the introduction of the new system of open competition. A considerable correspondence took place between the First Commissioner and Dr. Hooker, the Treasury, and the Civil Service Commissioners, respecting the mode of filling up the appointment, and the nature of the examination. In the end a person was appointed by an open competition in February 1872, not being the candidate nominated by Dr. Hooker. Being admitted to probation under the terms of her Majesty's Order in Council, the assistant has proved himself so well qualified for his office, that Dr. Hooker has recommended him to fill a vacancy in the superior grade, and he only waits the completion of the six months' probation to be recommended for promotion by the First Commissioner. Dr. Hooker, however, still proposes to revert to the practice of his own nomination. The First Commissioner having submitted the objection to open competition to the consideration of the Civil Service Commissioners, they concur with the First Commissioner in a course which appears to him to obviate all objection. The other case arises out of the discovery by the First Commissioner that the Curator of Kew Gardens had been grievously overtaxed in the performance of his duties, by being obliged to devote his evenings to a late hour on the accounts and correspondence at Kew.

THE CURATOR'S CLERK.

On the 1st July 1871, the accountant of the Office of Works reported on the management of the accounts at Kew, suggesting the appointment of a clerk. This report being sent to Dr. Hooker, he urged upon the First Commissioner the expediency of adopting that course. The Treasury sanctioned the creation of the office of clerk to the Curator. The usual arrangements were made between the secretary, the Civil Service Commissioners, and Dr. Hooker, for the appointment of the clerk by open competitive examination. On the 1st of February 1872 the clerk was appointed by the Civil Service Commissioners by open public competition. On this appointment being notified to Dr. Hooker, he forwarded a letter from the Curator of Kew Gardens, objecting to it on the ground that the clerk was utterly unfitted for the duties and responsibilities explained to him by the Curator. A correspondence then went on to ascertain what were the duties for which the clerk was fit or unfit, until the First Commissioner at length requested the Director to certify whether the clerk was fit to be employed on probation for the duties of the office as defined in Dr. Hooker's letter recommending its creation. On this the Director certified that he was unfit, and the First Commissioner referred the case to the Civil Service Commissioners for their consideration. The Civil Service Commissioners declined to cancel the appointment, and recommended that the clerk should be

taken on probation, and that if reported unfit at the end of six months, he should be discharged in terms of the Order in Council. The First Commissioner having in vain urged the Director to take this course, finally, after consulting the Treasury, which is the regulating authority, discharged the clerk, and communicated the result to the Civil Service Commissioners and to Dr. Hooker. The failure to appoint a competent clerk appears to the First Commissioner to be due to two causes; that sufficient publicity was not given to the proposed competition, and that sufficient precaution was not taken to ascertain the technical qualifications of the candidate. It is, however, to be observed, that if Dr. Hooker was prepared to nominate a competent clerk, it was his public duty to direct his nominee to go before the Civil Service Commissioners, and submit him to the test prescribed by the Order in Council, for there is no doubt that the clerk appointed by the Civil Service Commissioners was the most competent of the candidates. As these two offices are thus again vacant, the First Commissioner deems it right to institute a comparison between the proposal of the Director to nominate the officer, and the Order in Council to appoint by open competition. The superiority of private nomination can only be maintained on the ground that a person privately nominated will necessarily be better than anyone who may become a competitor when the vacancy is made known, or that the mode of conducting the competition does not admit of the real merits of the competitors being ascertained, and that the person to be privately nominated would be superseded by a person of inferior merit. The first proposition being untenable, it is apparent that the real objection is not to open competition, but to the mode in which the competition is conducted. The First Commissioner sees no reason to doubt that the Civil Service Commissioners can so conduct the examinations for technical appointments as to ensure the person best qualified for a technical service being appointed by them; he is satisfied that the arrangement last proposed by them will effect that object, and he therefore has not seen any sufficient reason to abandon the system of open competition in favour of private nomination in filling up the vacant offices at Kew.

THE ACCOUNTS.

As the correspondence above noticed shows that there is now a disinclination to have a clerk at all at Kew, it is proper to observe that the appointment was recommended not merely on grounds relating to Kew Gardens, but with reference to the general administration of the Office of Works, and the necessity in any properly organised establishment of providing a succession of competent persons for the performance of particular duties. There can be no duty more troublesome than that imposed on public servants, to receive and train probationers and persons newly entering the service, but this is as much a part of their duty as any other service they perform, and from this the establishment at Kew has no claim for exemption. It has now become necessary to revise the system of vouching and examining accounts in the Office of Works; at present all accounts from Kew are only signed by the Director, but every public voucher should be certified in the following particulars as completely as if the form of certificate were annexed to each account:—The authority for the expenditure; the sufficiency of the quantity and quality of the work or goods, according to contract or other proper standard, ascertained by actual weight, measure, or other process; the correct calculation of the rates of charge and of the total amount; the actual payments and receipts, according to the account. It cannot be expected that the Director of Kew is to undertake all these duties himself, but it will be necessary that every account should be signed by the person who actually performs this duty. It seems expedient that the accounts department at Kew should be strengthened, whilst the time of Director and Curator is left for their special functions.

KEW *v.* LONDON.

Without any communication with the First Commissioner, Dr. Hooker attended before the Commissioners on Scientific Instruction, and gave evidence respecting the administration at Kew; this having accidentally come to the knowledge of the First Commissioner, he requested the eminent naturalist, Professor Owen, to favour him with his views, raising very interesting questions. The House of Commons have sanctioned an expenditure of more than half a million of money for the purpose of constructing a new museum of natural history, and these important questions will have to be dealt with when the museum is ready for occupation:—Whether it is desirable on the grounds of science, public utility, efficiency, or economy, that two museums should be kept up, with their libraries and staff of public servants, to prosecute the science of botany, or whether an accomplished botanist might be placed in charge of the whole collection to be brought in correlation with Palaeontological botany, and the other branches of natural history? whether, having regard to the fact

that the Kensington Museum will be close to one station and Kew Gardens close to another, on a short line of railway, with telegraphic communication between one institution and the other, the chief botanist in the public service might superintend a complete botanical collection at Kensington, and illustrate it by lectures to male and female classes, and might give directions to the horticulturist at Kew to cultivate whatever specimens were required, and to forward such of them as might be necessary or convenient to be added to the museum, or to be used for demonstration? whether the chief botanist could visit Kew as often as he desired, with or without his classes, or reside there, coming to the museum during museum hours; whether the sum now spent on the collections, library, and establishment for botany at Kew, might be expended in completing and improving the establishment at Kensington, or be saved? whether the Curator of the gardens, receiving and complying with botanical requisitions, and obtaining botanical advice from the chief botanist, could manage Kew Gardens as effectually as accomplished and experienced horticulturists manage other gardens? and whether, having his efforts recognised by, and known to the public, he would be encouraged to new exertions by the well-merited reward of public approbation? Though these questions need not, and as the First Commissioner thinks ought not, to be solved until the circumstances which may exist at the time of the completion of the new museum are fully considered, it appears to the First Commissioner to be his duty to take care that in the meantime no new expense is incurred at Kew which will in the least embarrass the Ministers of the Crown or the House of Commons in arriving at a decision.

KEW GARDENS.

No one who has known Kew since Aiton's time, and who, like the writer, has watched its progress, can hesitate to say that, judged either from a cultural or artistic point of view, it has been seen in much better condition than it is in at the present time. Its flower gardening, closely looked into, is inferior to that of many of the parks, while the plant cultivation, taken as a whole, is not superior to that of many third-rate establishments. The excuse which a contemporary has made for this is a very feeble one; there is no more reason why the plants at Kew should not be perfectly grown, than that the Duke of Devonshire or Sutherland should not have superior fruits, simply because their establishments are larger and require more management than those of the squire, parson, or tradesman close by. The reason why small establishments are frequently better managed than large ones is often because they do not attempt more than they can manage.

"Oh, hut," exclaims some scientific enthusiast, "look at the botanical interest?" Well, I have looked, and having identified a lot of things which have neither cultural, commercial, nor decorative interest, see no more need for retaining them, except in the herbarium, than for retaining the crop of weeds which, unmoested, would soon choke my supply of Cabbage and Lettuce plants. If the plants have any value in the arts, manufactures, or medicine, retain them; but if they have no value in any of these, and fail as regards decorative purposes, then I say relegate them to the rubbish heap. Apply this rule to Kew, not with an arbitrary hand, and there would be ample room to grow most plants, if some one who knew their wants and capabilities had the management of them. But Kew is great in natural features. Recently when walking through, and noticing that many of the tree Ferns, Palms, &c., were disfigured by dead fronds—further disfigured and wreathed together by mealy-bug and other insect pests—I asked one of the attendants why the fronds were not removed; he answered, "We are forbidden to remove them, the authorities considering it natural that plants should have dead leaves." Nature does her work in her own way; the tornado or the storm may do the necessary plant scavenging, but it is different in our plant houses, where only the soft sighs of the west wind are allowed to breathe upon the plants, and there, in consequence, man must remove the leaves which under other circumstances plants would get rid of in a natural manner. Nature is a capital handmaiden, a safe guide; but if under artificial conditions we follow her slavishly, unthinkingly, we are safe to be landed in a dilemma.

From what Mr. Croucher has said, and from what I have heard from other employes, past and present, at Kew, I am far from believing it is the best managed horticultural establishment in the country. As has been already shown, the flower gardening and plant culture are bad, and the landscape work, whoever may be responsible for it, is simply contemptible. As a botanist, Dr. Hooker is undoubtedly entitled to rank with the foremost savans of the times, but judging by the present state of Kew, I should certainly hesitate, if I wanted a gardener, before engaging Dr. Hooker in that capacity. For the vast sums of money expended, the country is entitled to much more value than we at present get at Kew.

While some of the parks are really well done, we have no right to sit down with respectable mediocrity in the most liberally endowed botanic garden in the world.

R. H.

[We must say that we think the old fronds a great improvement to the aspect of tree Ferns, especially after a good layer of them has fallen down; and some think they are slightly beneficial. We, however, know no other class of plants of which the same could be said.]

GARDENING FOR SEPTEMBER.

THE INDOOR GARDEN.

BY T. BAINES, SOUTHGATE.

Conservatory.—The most attractive flowering plants in conservatories for the present month will be the different varieties of *Lilium speciosum*, *Vallota purpurea*, the good old, but often neglected *Rochea falcata*, and the still rarer *Griffinia hyacinthina*. If these things are grown well in sufficient quantities, intermixed with the general occupants of the conservatory, they will keep up a display for five or six weeks, especially if a portion of the stock is retarded by being placed where it will receive comparatively little sun and abundance of air. See that all these things receive regular attention as regards water, as any omission in this matter will make short work of the blooms, and in the case of the Lilies will destroy the foliage. Keep a good look-out for that most destructive of all plant pests, red spider. If allowed to establish itself even thus late in the year, it does irreparable damage for another season by premature destruction of the foliage of any plant which it happens to attack. *Chrysanthemums* will now require rich and copious waterings twice a day if the weather is dry, and their pots are filled with roots, as they ought to be by this time. Syringe them overhead in the evenings of bright days; if this is attended to they rarely get infested with greenfly. Pay every attention to winter-flowering plants, such as *Cinerarias*, *Primulas*, *Euphorbias*, *Poinsettias*, *Bonvardias*, *Salvias*, &c.; the more stout and robust these plants are now, the better they will bloom, provided they are well ripened. If *Poinsettias* and *Euphorbia jacquiniiflora* have been placed in a cooler situation during the last month than they have previously occupied, they should be removed from such a position before the nights become too cold, or both leaves and roots will suffer, which will be fatal to their blooming. By the third week in the month, all the occupants of the stove and intermediate house that have been used for conservatory decoration during summer should be removed to warmer quarters, otherwise they will be injured. *Achimenes*, *Tydas*, *Gesneras*, and *Gloxinias*, should now be dried off and put to rest, placing them in a situation free from damp, where the temperature will not get lower than 50°, otherwise they are in danger of rotting. See that pot *Roses* out in their summer quarters are sufficiently supplied with water, and that their foliage is kept free from mildew by applications of sulphur, should that pest make its appearance. *Eucharis amazonica* should also now be placed in a warmer temperature than that of the conservatory, or it will suffer. If a late sowing of *Asters* has been made with a view to their being potted for conservatory decoration when coming into flower about the end of the month, provision should be made for covering the bed with loose lights to protect them. See that such things as *Acacias* and *Cytisus* are fully exposed to the sun in an open situation, for the better they get hardened out of doors the more satisfactory will be their blooming. Put in another batch of *Hydrangea* cuttings; these will bloom late in the summer if kept cool during the spring, and will come in when flowering plants are scarce. Attend well to herbaceous *Calceolarias*, so as to get the plants stout and strong; by this means they get so much better through the winter. Conservatory climbers should now be regulated, reducing freely all excessive growth, so as to allow of its being sufficiently thin for each plant to get thoroughly ripened before the short days are upon us.

Stove.—Reduce the shading here to a minimum, but do not remove it altogether, for sometimes we get extremely bright weather even up to the end of the month, by which very much injury is done by scorching, especially as it is necessary now to use much less moisture in the atmosphere, as well as to admit more air; both of which render the foliage more liable to scorch. The object of the cultivator in this matter ought to be to just shade sufficiently to prevent injury, but no more, not even for a single hour. This is a point the importance of which I would urge, as so much depends upon the manner in which stove-plants are treated in this respect, during this and the following month, with a view to their flowering freely the ensuing season. From *Allamandas*, *Clerodendrons*, and *Bougainvilleas*, gradually withhold water, allowing them to flag for a day or so before giving any, and then only give it in reduced quantities; by continuing this treatment the soil in the pots will gradually get to that (at this time of year) necessary condition as to moisture, that it contains just sufficient moisture to maintain the roots in health, without inducing any disposition in the plants to form more wood. *Stephanotis* requires to be kept after this time comparatively dry; but unlike the preceding plants, being evergreen, it will not answer if the soil gets too dry, as the leaves would suffer and drop off. *Dipladenias* should also be kept drier than when it is desirable to encourage

active growth, yet not so dry even as the *Stephanotis*. *Ixoras* again must be kept at this season drier than when their growth is most active, but must never be allowed to get too dry, or they will suffer to an extent that will take the best part of a season to recover them. Nothing adds more to the good appearance of the stove than a few suspended baskets of such things as *Hoya bella* or the different varieties of *Æschynanthus*; of the latter, *A. splendens* and *A. Boschianns* are most desirable plants, of graceful drooping habit, brilliant and free-flowering; growing freely in an equal mixture of loam and peat, with sufficient sand to insure porosity.

Fern House.—Reduce the atmospheric moisture here, and also the roof-shading, but this only in a comparative degree, Ferns having no wood to mature and solidify like flowering plants, neither require, nor will they bear this additional sunlight and drier root treatment being carried so far as in the case of flowering plants, without suffering seriously. What they do require at this season is simply to carry this treatment so far as to check the disposition to make growth and rest the plants, so as to get them in that condition that they will move with vigour when the season of active growth comes round.

Azaleas.—The late-blooming plants will now be setting their flower buds, and should be no more shaded. The syringe should also be withheld, simply throwing a moderate amount of water about the floors and paths, at say four o'clock, when the house should be closed, allowing the temperature to rise by sun-heat, which is at once the most genial to the plants and the most economical. Continue this practice until the flower-buds are up as large as small *Camellia* buds. If their inveterate enemy, the thrips, makes its appearance, give it no quarter; any delay in this matter entails a serious after expenditure of labour. Get all the plants, large and small, tied before they have quite completed their growth and the wood becomes hardened thoroughly, as after this they are too stiff to regain the natural position of their shoots after tying.

Hard-wooded Plants.—These will now be out of doors to harden and mature their season's growth. See that they are well attended to with water, and syringe in the evenings all such as are not liable in the winter to the attacks of mildew. On the other hand, see that they do not get their soil too much drenched by heavy rains, otherwise irreparable injury will follow.

Orchids.—As the days shorten use correspondingly less shading; that is, do not draw down the blinds so early in the mornings, and remove them earlier in the afternoon than hitherto; also diminish somewhat the amount of atmospheric moisture. All plants nearly finishing growth require to be kept drier at the root. Where there is not the convenience of different houses to accommodate plants at rest apart from such as are growing, and which require more heat and moisture, the growing plants ought to occupy the warmest end of the house, at which apply all the moisture given to the house, and admit all the air required at the opposite end, where the plants are placed that have finished their growth. This may appear somewhat of a makeshift arrangement, nevertheless I have seen some of the best grown plants I have ever met with, where such was the only arrangement possible.

Heaths.—These should all be now fully exposed in the open air, except such as evince, by the absence of free growth, that they are weak at the roots. If any such exist it is better to keep them under cover, giving all the air possible night and day, and be careful not to let them get too wet at the roots. Heaths that become somewhat stagnant at the roots in the way described may sometimes be brought round by careful treatment of the soil, whereas if they are subjected to the trying ordeal of full exposure, the chances are that they will perish.

THE FLOWER GARDEN FOR SEPTEMBER.

BY GEORGE WESTLAND, WILEY COURT.

The favourable weather which we have had during the last fortnight has induced most plants to bloom in great profusion, whilst the fresh verdure of the grass sets them off to increased advantage; both foliage and flowering plants are now, indeed, in the best possible condition. Fine, however, as *Geraniums* are, I perceive a great and growing mistake in their excessive use in the embellishment of our gardens. I have seen several places this season where they have been used almost exclusively. I have no hesitation in assigning to them the first place among summer flowering plants; but *Geranium* gardens I consider to be neither elegant nor pleasing; therefore it would be advantageous to confine their use to reasonable limits, especially when there are so many other fine flowering and foliage plants to select from. As the season advances the greatest vigilance will be required to render flower gardens enjoyable to the longest possible period by so regulating the growth as to preserve proper

outlines, more particularly in the case of geometric designs, removing all faded blossoms and decayed leaves.

Dahlias and Hollyhocks should have their branches occasionally tied up, so as to secure them from being broken by high winds. A successional sowing of hardy Californian annuals should now be made, as those sown now stand the winter best. The most suitable situation for them is one that is somewhat sheltered, yet not overhung, by trees, and they like a rather poor soil. As a list of the best for spring decoration may be desirable, in addition to those previously named, the following will be found useful, viz.: *Eucharidium graudiflorum*, *Clarkia pulchella*, *Eutoca viscida*, *Nemophilas*, *Whitlavia grandiflora*, *Silene vespertina*, *Godetias*, and *Virginian Stocks*. Attend to the thinning out of those previously sown as soon as they are fit to handle. Plant out Pinks, Pansies, Carnations, and Picotees that are sufficiently rooted, and pot up such as have been prepared from the open border for early forcing. This is a good time to apply salt to garden walks; choosing a dry day, if possible, for the operation. It is a good plan to turn up the edges of the walks with a hoe previously to scattering the salt, which will protect the verge from being damaged; otherwise do not salt nearer to the edging than a foot without proper precautions. I have known it washed into the edging with the most destructive effect.

The propagation of evergreens should now be seen to; and from the middle of September to November is the most favourable season for transplanting the generality of trees and shrubs. Anything in the shape of disarrangement, however, must be avoided; but the earlier in the season the planting can be done the greater are the chances of success, and that, too, with little after labour. Clematises are now flowering in great splendour, creeping over beds, and are worthy of every attention so as to lengthen the season of bloom. For this purpose water freely with liquid manure, which should also be extended to all plants that show the least signs of exhaustion, either from flowering or poor soil.

Pits and Frames.—Propagation should now be vigorously pursued. The young shoots of the Japanese Honeysuckle (*Lonicera aureo reticulata*) will strike now as freely as a Verbena, and when seen in really good trim it makes a most charming edging, perhaps unequalled by any other golden edging we possess when frequently cut down. Geraniums should be potted from the open ground as soon as rooted. I never had a finer strike of these than I have this year in the open ground. Continue to pot off all kinds of cuttings as they become sufficiently rooted, and expose such as are thoroughly established by placing them in exposed places upon a bed of ashes, as they stand the winter with far less care when properly hardened than when in a comparatively soft state. Sow Ten-week Stocks and Mignonette for succession.

One of the most important things claiming attention at this season is preparing bulbs for early forcing; success in a great measure depends upon their being obtained in time and potted early in the month. The common cheap single kinds are by far the best for early work, and a turfy loam and thoroughly decayed manure, rendered porous with sand, will be found a good compost. For the earliest batch I do not think that so large or deep pots as are recommended are at all necessary; indeed, I find growing the majority with three and five roots in a 6, 7, or 8-inch pot to answer well; we look upon it in short as a great mistake to plant roots in large pots for early forcing. I have for years selected from the best bedding-out sorts, which are bought cheaply, the best roots, and plant from ten to twelve bulbs in 12 and 13-inch pans, from which I get good spikes of flower, and I have often been better satisfied with these than with large and more expensive roots. After potting give a good watering, and place the pots upon ashes, to prevent the ingress of worms, and when the surface has dried a little, cover the whole with sifted ashes for a month or so, in order to encourage root action before the top gets excited.

THE FRUIT GARDEN FOR SEPTEMBER.

BY WILLIAM TILLERY, WELBECK.

Outdoor Fruits.—The rainfall in the beginning of August was again excessive, nearly two inches having fallen up till the middle of the month in this locality. On the 15th a fine, dry, warm period set in, which has helped to ripen the buds of fruit trees on walls and in the borders. Where the foreshortening and nipping in of the shoots and laterals of the bush and pyramidal trees in the borders have been neglected, no time should be lost to get this done so as to give the trees a chance of ripening their wood. The gathering and storing of the crops of Pears and Apples this autumn will not take up much time or attention, but what there are will soon have to be looked after as they ripen, and the fruit-room cleaned and prepared for their

reception. Pears should be laid singly on the shelves of the fruit room, as well as the best sorts of Apples, and they are much improved in flavour by keeping them in a dry, warm place for a few days, before being used for the dessert. That beautiful little early Pear, the Doyenné d'Ete, has with me been very fine this year on an east wall, as well as on standards; Maria Louise, Bœurré Superfin, Glou Morceaux, the Seckle, Louise Bonne, and Winter Nelis on the walls and on a wire trellis, have likewise cropped well. With me, Apples of all sorts are a complete failure; the Oldenburgh, a Russian sort, and Lord Suffield, being the only varieties that have shown a fair sprinkling on the trees. There never was a finer show of bloom, but the frost and sleet showers in the spring cut it all off. Small fruit, on the whole, was a better crop than was expected here, and if the Strawberries had not been injured by the constant heavy rains in July, there would have been a very plentiful crop. In making a selection of Strawberries for planting out, the Elton Pine should not be overlooked, for it is the best late sort we have to prolong the season; the Frogmore Late Pine is another good-flavoured late kind, but on some soils it does not grow well. For the last two seasons I have grown immense crops of the Lawton American Blackberry, and the fruit makes the most delicious of all preserves, mixed with a few Apples to take off the sweetness. Some of the varieties of the autumn fruiting Raspberries are likewise deemed invaluable here for furnishing nice dishes of fruit for the autumn dessert, or for making ices with. I therefore highly recommend the planting of these fruits to all who do not grow them. The Strawberries intended for forcing should be in their fruiting pots as soon as possible. They should be set in beds in some open, sunny situation, and on a stratum of ashes to prevent worms from entering the pots. All the runners must be pinched off as soon as they appear, and, if the weather be dry, the plants must be freely watered.

Vineries.—The foliage of the vines in the early house will now be quite ripe and falling, and the vines may be pruned and dressed for forcing in November. Vines in pots for early forcing may be placed out of doors, and the pots should be laid on their sides in very wet weather, to prevent the roots from being too much drenched before they are taken into the forcing houses. Late vineries, wherein Grapes are ripening, should have plenty of air in favourable weather, and some at night in dull cold weather, when fire heat is applied. All outside borders should, if possible, be covered with lights, or wooden shutters to keep them dry, before the cold autumn rains chill the roots.

Peach Houses.—The crops of Peaches and Nectarines in the late houses will now be nearly all ripe, and when the fruit is all gathered the trees must be well syringed with soft soap, or Gishurst's Compound, to prevent the brown scale from attacking the wood. The trees in the early houses which have ripened their wood may now have the foliage brushed off with a new broom, and the wood loosened from the trellis. Now is a good time to get a store of turfy loam stacked up to keep it dry, should the planting of Peach and Nectarine trees be decided on in October or November, either for out of doors or in the houses. I find Peach and Nectarine trees do best in fresh turfy loam without the addition of manure of any kind in the soil, as it only makes them produce strong watery shoots, which never ripen well. Of all things to be avoided in the soil is rotten old tan, vegetable mould, or any material containing pieces of rotten sticks, for they all breed fungi, and when they attack the roots of Peach trees they are soon totally unproductive. The roots of vines are likewise liable to be attacked by them, and the failures in crops of Grapes from these are often attributed to some other cause.

Orchard Houses.—When the fruit is all gathered from the trees in pots in these structures, the pots may be placed out of doors, and if they are plunged in some warm corner, it will save some watering. The late crops of Peaches and Nectarines, Plums, and so on, will want a thorough watering now, to swell the fruit. In cool orchard houses, some of the late varieties of Peaches and Plums can be kept later than those on the walls or open borders.

Cucumbers.—Too much syringing will now be injurious to late Cucumber plants, as the sun's heat will be gradually declining. If thrips put in an appearance, remove the infested leaves, which are generally the old ones, and famigate two or three times at the intervals of four or five days, till that pest is conquered. Mildew will sometimes attack Cucumbers in frames or damp pits, and flowers of sulphur must be applied till it disappears. The plants intended for the winter supply must now be planted in the house or pit as early in the month as possible, on purpose to get them strong before the short days set in. The soil for them is most suitable when of a light sandy loam, enriched with old frame manure, or that from a spent Mushroom bed.

THE PINERY FOR SEPTEMBER.

BY JAMES BARNES.

WE have now arrived at the kindest growing part of the season, so that little trouble or anxiety is necessary in any department. Fruit will colour freely by the application of abundance of light and air, and the withholding of humidity. Swelling fruit requires applications of tepid, clear manure water, kindly applications in suitable weather of atmospheric humidity, and the interior atmosphere charged with ammonia. Air freely by day, and use no shading. From plants now showing flower, atmospheric moisture should be withheld till after they have bloomed, after which apply it freely. Plants intended to show fruit in October and November should now be aired freely, night and day, humidity withheld, and root waterings not too freely applied; but never let them be famished for lack of water, or they will produce weak and abortive fruit. Plants intended to rest and harden in October and November for starting into fruit in December and January next, should meet with every growing encouragement by the application of tepid manure-water at root, humid, kindly heated atmosphere, plenty of air night and day, gradually reducing the atmospheric heat as the days decrease. Succession plants in every stage have arrived at the very best part of their growing season, and require previous instructions fully carried out, and the night atmosphere reduced somewhat as the days decrease. The application of abundance of air in maintaining healthiness and a robust growth, abundance of heat, air, and humidity, and no shading, is sure to command all that can be wished. Suckers, of course, should be taken off and potted at once; to grow on, without loss of time or check, is the only way to succeed in always having at command fine, healthy plants, in every stage, at all seasons.

THE KITCHEN GARDEN FOR SEPTEMBER.

BY JAMES BARNES.

CONTINUE to prick out Cabbage plants a few inches apart as fast as they are large enough to be handled. Do not select over-rich land for this purpose, but sweet, healthy, rather poor soil; more particularly for all the late prickings intended to stand the winter, in order that the plants may not become too soft to stand the winter well. There is no need of having long, crooked, or shanked Cabbage plants that are awkward to handle and take more time to plant than others; besides they are not likely to thrive so well; it is only by thick sowings and neglect of timely thinning that such distorted rubbish is produced. The right time of year, to enjoy pretty little and sweet Cabbages and Coleworts is from September to February, and good spring Cabbages in March, April, and May. In order to have these then, it is necessary to plant timely and thin, keep the ground constantly open and loose by a free use of the hoe. The Cabbage is a wholesome and useful vegetable for every day's consumption, a substitute for which is not easily found. It is also on it we place our greatest dependence in case of Potato failure. Manure, trench, and ridge up in as rough and open a manner as possible the ground from which the Onion crop has been harvested, in order that it may readily receive the beneficial influence of the sun and atmosphere, a rare change for Cabbage if the ridges are cast into 30-inch trenches. When the first batch of pricked-off plants are strong enough, they should be planted on each side of the ridge 15 inches apart. If the ridges are cast 24 inches apart, insert the plants on each side 12 inches apart each way; this brings your plants even 12 inches apart each way; and this distance gives abundant room for pretty-sized early Cabbage, if timely thinning is attended to. The roughly cast ridges will shelter and break the cold winds, and the scarifying down and about the plants as the season advances encourages a healthy sturdy growth, a practice everywhere to be observed. The plants placed 2 feet to 2 feet 6 inches apart on flat ground, open to the full exposure of all cutting winds and weather during the winter, by the month of March, when nice little healthy Cabbages should be ready for use, there are only weather-beaten, crippled, and diseased plants, and many quite dead, after a severe winter; while those that are alive have still their growth to make, coming in late, and at a time when other vegetables are plentiful. There is little pleasure or enjoyment in a large or small weather-beaten, sunburnt Cabbage during the long hot summer days when other vegetables should be fully in season, and when caterpillars and grubs are abundant; besides, what is the enjoyment or value of those great, heavy, hard Cabbages that we see so commonly offered for use, and frequently meet with weighed and cut open for competition at our country summer exhibitions, except for cows and pigs? There is a time to be observed every season in the spring months when vegetables are scarce and dear, when they should be abundantly supplied, and most assuredly can be, which I can fully vouch by my own long practice. In many localities it is

distressing to observe the negligent manner in which the soil is cultivated, and the trash it is burdened with, for we often see lumbering slow-growing wild leafy Cabbage, not far in advance of our native wild Cabbage, to be found growing round our coast. Plant out with Coleworts any spare ground you may have, and continue to use the hoe frequently amongst them.
